Mr. John Talbot asked the President of the Local Government Board whether, after the recent decision of the House of Lords in the Hampstead Hospital case, he is prepared, by legislation or otherwise, to secure to the inhabitants of the metropolis the advantages which were intended to be conferred by the establishment of hospitals for fever and small-pox under the provisions of the Metropolis Poor Act, 1867. Mr. Dodson said he was desirous of securing to the inhabitants of the metropolis the advantages intended to be conferred by the establishment of hospitals for small-pox cases under the Metropolis Poor Act; but the matter was one of much complication, and he was not prepared, until he had had more time to review the whole subject, to indicate what steps should in his opinion be taken to meet the present difficulty. He might add that the recent decision of the House of Lords had only been given with regard to one of the appeals in the case, and a month had been allowed to the managers to prosecute the second appeal if they thought proper to do so.

Scotch Medical Relief.

Mr. Crum asked the Financial Secretary to the Treasury whether, after hearing the statement of a deputation from the parochial boards of Scotland, he had given an undertaking that he would grant an increase in the medical poor-law grants if the parochial boards were willing to allow the poor-law supervision to exercise some control over the appointment and dismissal of their medical officers. Lord F. Cavendish thanked his honourable friend for the opportunity thus afforded him of removing a misapprehension. He pointed out to the deputation that if Scotland was to be placed in the same position as England with regard to grants in aid of medical relief the conditions must be the same, which could only be done by legislation. In equalising these grants consideration should be given to others, such as that for pauper lunatics. The Government were considering the subject at large, and meanwhile they would not increase the grant.

On Tuesday, in reply to Mr. Hopwood, the Marquis of Hartington admitted that the Contagious Diseases Acts had been reapplied to Bombay, in spite of a strong objection expressed by a large number of influential natives and Europeans; but stated that it was found necessary to do so, and every precaution had been taken to limit the operation of the Acts strictly to the class of women for whom they were intended.

Army Medical Officers.

On Wednesday the following notice was given for Monday:—Mr. Findlater, to ask the Secretary for War whether, having regard to the cases of wounds and sickness which have occurred amongst medical officers during recent campaigns, he will take into consideration the justice of extending to the Army Medical Department the privilege now enjoyed by all combatant officers of counting as full-pay service towards retirement any time on half-pay, not exceeding one year, when such half-pay has been necessitated by sickness incurred in and by the Service; also such half-pay as results from reduction of the department, not exceeding two years, as laid down in Army Circulars, March 1st, 1880.

On Thursday, on the motion of Mr. Pease, an address was agreed to for a return of the number of painless and painful experiments performed on living animals during the year 1880 under the 39th and 40th Vic. On the motion of Mr. Courtney a return was ordered of the annual report of the Assistant-Commissioner of Metropolitan Police for the year 1880 relating to the Contagious Diseases Acts.

Animal Vaccine.

Mr. P. A. Taylor gave notice that on Tuesday next he would ask the President of the Local Government Board if he would state to the House the source whence the new animal lymph was to be obtained, whether the calves were now inoculated from a diseased horse, or from a human being suffering from small-pox, or from what other source. Dr. Cameron asked the President of the Local Government Board whether any steps have been taken to give effect to his promise, made on the 11th of June last, that the Vaccination Department should supply calf lymph as "stock" for vaccination to such medical practitioners as preferred it to ordinary humanised lymph; and whether, in view of the alarming spread of small-pox in London, the department would consider the propriety of taking measures to secure a sufficient supply of vaccine lymph for the purpose of revaccination. Mr. Dodson: Yes, sir; steps have been taken in pursuance of that promise. Careful inquiry has been made by the medical officers of the Local Government Board as to the arrangements in Belgium and elsewhere for the supply of calf lymph, and we have been engaged for some time in endeavouring to find suitable premises for an establishment in the metropolis. This has been a matter of some difficulty, but I am happy to say that the matter has so far progressed as to enable me to appoint a medical director for the establishment, and to arrange with the Treasury as to the staff. In answer to the last question I have already stated that the department is not intended to supply a sufficient quantity of lymph for revaccination. The object for which the National Vaccination Establishment was set up was to supply a certain quantity of lymph for the purposes of primary vaccination.

The Indian Army Medical Department.

Sir Trevor Lawrence asked the Secretary of State for India when the despatches regarding the reorganisation of the Indian Army Medical Department promised by him will be placed upon the table of the House; and when the Royal Warrant fixing the new scale of retiring allowances for Indian medical officers will be published. The Marquis of Hartington said papers on the subject were being prepared for presentation to Parliament, but in order to make the case complete it was thought desirable to include a despatch of the Government of India containing a statement of the nature of the improved scale of pensions for the medical service. As soon as the despatch was approved by the Council papers would be presented.

Correspondence.

"Audi alteram partem."

FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

To the Editor of The Lancet.

Sir,—More than a quarter of a century since, when I became a Fellow of the Royal College of Surgeons of Edinburgh, by examination, and after a long course of study, it was an honour and a distinction to possess this diploma. The older Fellows must have seen with regret the deterioration of the qualification during the later years, and must, as I do, feel great cause of thankfulness to yourself and others who are endeavouring to awaken the Edinburgh College to a sense of its responsibilities to the public, the profession, and to its own members.

It is humiliating to have a qualification which I have held and valued so long dragged in the dirt as a bogus diploma, and it is, besides, a great injustice.

Yours faithfully,
March 8th, 1881. An Old Fellow by Examination.

To the Editor of The Lancet.

Sir,—I have read with interest the leader in your issue of March 5th on the Fellowship of the Royal College of Surgeons of Edinburgh, and must applaud your outburst of virtuous indignation against honorary distinctions. I should, however, be glad to see you go a little further, and include in the condemnation the other Colleges besides those of Scotland which also grant Fellowships and other higher titles without further examination. These are the Royal College of Physicians of London, the Royal College of Surgeons of England, and the King and Queen's College of Physicians in Ireland. From an answer to a correspondent in The Lancet for Oct. 23rd, 1880, I learn that there were in the Calendar of the College of Surgeons for that year the names of 1215 Fellows, 558 of whom obtained the distinction after examination. On 657, therefore, the distinction must have been conferred without examination; and many of these took their diplomas of Member years ago, when the examinations for that qualification were, to put it mildly, less severe than they are now.

The whole question of the granting of higher distinctions to gentlemen already qualified, without further examination, is one well worthy of discussion; but it is scarcely fair that the Scotch Colleges should be held up for execration as if they were the only corporations which followed the practice. Nor has the Edinburgh College of Surgeons been so lavish in its bestowal of Fellowships as might be supposed from your article. On the 20th October, 1880, the number of Fellows of the College was 463, whereas at the same period it appears, from what I said above, that there were 657 Fellows of the English College who had obtained the distinction without examination. I hope you will follow up your leader with an equally vigorous attack on *all* honorary medical qualifications.

Trusting to your sense of justice to insert this, I remain, yours faithfully, F.R.C.S. Ed., M.R.C.S. Eng.
March, 1881.

INTRA-UTERINE STEMS.

To the Editor of The Lancet.

Sir,—In The Lancet of March 5th, under the heading "Ovarian Dysmenorrhœa, with Retroflexion," &c., Dr. Ernest Herman states that his letter "has elicited from Dr. Wynn Williams that he does not know the termination of many of the cases which he has treated with his intra-uterine stems," and enters into a tirade against uterine stems generally, but considers that the one associated with my name is the least dangerous. I should strongly recommend Dr. Ernest Herman to read over his request for information, and he will find he asks to be informed how many cases were followed by impregnation after wearing the stem and shield, not whether any dangerous symptoms followed the introduction. Dr. Ernest Herman makes a most unjustifiable statement in the remark, "Dr. Wynn Williams has not seen any bad results, because he has not inquired as to the subsequent course of all his cases." The knowledge as to the termination of the cases, and the knowledge as to whether the patients became pregnant, is, as your readers can well understand, quite another thing. I defy Dr. Ernest Herman to bring forward a single instance of death following the introduction of the stem and shield in one of my own patients. That death has followed the introduction and use of *fixed* instruments I think no one will be found to deny. I never heard of but one instance where a patient of mine fell into the hands of another practitioner when anything like serious symptoms followed the use of the stem and shield, and that was mentioned at the Obstetrical Society some years ago by Dr. Edis. The case mentioned by Dr. Daly had nothing whatever to do with the stem and shield.

In my own practice I have never seen any ill consequences follow the introduction of the stem and shield that has not been immediately remedied by its removal. I have seen much more serious mischief follow the clumsy introduction of the sound, and how many deaths have followed the abuse of the hysterotome it would be difficult to state. In conclusion, I beg to assure your readers that I am fully cognisant of all the cases I have treated with the stem and shield, and they amount to many scores; so far no death has followed, but as to how many became pregnant, the greater majority having been unmarried, it is impossible for me to state. I may, however, be allowed to state that since the publication of my remarks in your valuable journal I have received several letters from medical men informing me of patients who have become pregnant after wearing the instrument associated with my name, and also from patients themselves who had heretofore been sterile and suffering from dysmenorrhœa, due to anteflexion.

I am, Sir, yours truly,
Montagu-square, March 7th, 1881. A. Wynn Williams.

"ABERYSTWYTH: A FASHIONABLE WATERING-PLACE."

To the Editor of The Lancet.

Sir,—We, the undersigned members of the medical profession practising in Aberystwyth, beg to express our astonishment at the remarks made in the last issue of The Lancet under the above heading. It is quite clear that you have been misled by the misrepresentations that have from time to time appeared in the *Cambrian News*. We fearlessly assert, and are prepared to prove, that nothing exists in this town to justify the conclusions you have come to as to its sanitary condition.

As to our sanitary arrangements we submit the following facts. Our new gravitation scheme provides the town with an abundant and continuous supply of water, pronounced by Frankland as one of the finest and purest in the United Kingdom. The drainage of the town, which was thoroughly carried out by an eminent engineer at a very large outlay, was finally inspected and highly approved of by Mr. Arnold Taylor, one of the Local Government Board Inspectors. As to the general sanitary arrangements of the town, we can safely pronounce them to be all that can be wished for. It is scarcely necessary for us to point out to you how seriously a paragraph such as the one referred to appearing in your valuable journal affects the interest of a town which so much depends upon visitors.

We confidently appeal to you to give the same prominence to this refutation that was given to the paragraph in question.

We are, Sir, your obedient Servants,
THOS. D. HARRIES, F.R.C.S. (Exam.) Eng.
C. RICE WILLIAMS, M.D.
RICHARD GILBERTSON, M.R.C.S.
MORRIS JONES, Med. Off. of Health, Aberystwyth.
JACOB ROBERTS, M.R.C.S.
JOHN MORGAN JONES, M.R.C.S.E.

THE DANGER OF NON-COMBATANTS IN BATTLE.

To the Editor of THE LANCET.

SIR, — As many people not conversant with military matters are undoubtedly under the impression that medical officers are but little if at all exposed to danger in war, and as they are consequently relegated to a position less honourable than their combatant brothers (for in battle the post of danger is the post of honour), it appears to me that every opportunity should be taken to dissipate these erroneous opinions.

Recently in the House of Commons the Under-Secretary of the Navy pointed triumphantly to the number of fatal casualties among the officers and men of the Naval Brigade engaged in the defence of the Majuba mountain as affording abundant evidence that the British sailor, now as in the days of Nelson, knows how to do his duty. Accepting this as a fair standard of the bravery of combatants, whose duty is to fight, it must also be accepted as regards the so-called medical non-combatants, whose more special duty is coolly to aid their wounded fellows in times of danger, but who, as the records of battle and the following statistics show, often combat the enemy as well:—

	No. of Officers engaged.	Killed or died of wounds.	Wnded.	Un-wounded Prisoners.	Wounded Pri-soners.	Escapd.
Army Officers	31	2	7	6	1	13
Naval Officers	2	2	0	0	0	0
Medical Officers	2	2	0	0	0	0
Army Service Corps	1	0	0	0	1	(?)

These records speak for themselves. The number of medical officers may be too limited for strict comparison, but they are as numerous as the officers of the Naval contingent. And if of these and also of Army officers it has been truly said that they nobly did their duty, it cannot be denied that the non-combatant medical officers most nobly did theirs.

I assume I am correct in stating that the number of medical officers engaged were two, as it is very unlikely that more would be attached at the front with three or four hundred men; moreover, no others appear in the lists from the seat of war.—I am, Sir, your obedient servant,

D. H. CULLIMORE,
Surg. I.M.D. (retired).
Connaught-square, March 6th, 1881.

IRELAND.

(*From our own Correspondent.*)

UP to the present, so far as can be gleaned in reference to the plan of organisation for the Royal University of Ireland, it appears that the inducements to students are of the amplest kind, the pecuniary attractions being most profuse. It is, however, one thing to formulate a scheme for endowments in connexion with a university, and a totally different thing to find that the Government will adopt the scheme as proposed in its entirety, and pledge itself to support it in the liberal manner suggested.

Dublin, for a considerable period, has exhibited an excessive death-rate as compared with other cities, and the returns for the past year prove that no improvement in this respect has taken place. So far back as July last, a resolution was adopted by the Council of the Irish College of Surgeons that an expression of opinion should emanate from them in reference to the causes which had produced, and were still producing, the unhealthy state of the city, and the abnormally high death-rate in Dublin. For this purpose a committee was appointed to confer with the College of Physicians in Ireland, and make a report as soon as possible to the council. Eight months have now elapsed since this resolution was passed, and at last the conjoint report of the colleges has been issued. The report attributes the extraordinary mortality of Dublin chiefly to the general insanitary arrangements of dwellings, the uncleanly and intemperate habits of certain classes of the people, and the spread of infection. The Colleges suggest the adoption by the Public Health Committee of certain measures calculated to remove the evils and defects indicated.

The Committee of the National Eye and Ear Infirmary, Dublin, in their report for 1880, state that there was an increase in the number of patients admitted to the wards of the hospital, and in the total number of patients registered. The hospital will continue in its old premises, Stephen's-green, until the end of March or beginning of April, when it will be moved to Molesworth-street, when some important alterations and additions have been completed. The new hospital will contain thirteen male beds, and an equal number for females, with separate day-rooms for each sex, operating-room, ample accommodation for nurses, and also, if desired, accommodation for a resident surgeon.

In the report of the Education Committee of the Royal College of Surgeons upon the proposed Scheme of Education and Examination for this College, which is now under consideration by the Council, it is satisfactory to learn that Midwifery is included in the list of subjects upon which a candidate will be examined. A considerable amount of doubt exists as to whether, when the various suggestions of the Education Committee are approved by the Council, it will come into force, or whether it must first receive the sanction of the Fellows at large.

It is intended by the friends of the late Dr. Peele of Dublin to erect a window with a mural tablet in St. Patrick's Cathedral to the memory of the deceased. An influential committee has been appointed to carry out this object, and to receive subscriptions, which are limited to one guinea.

Dublin, March 15th.

Obituary.

FRANCIS GODRICH, M.R.C.S., L.S.A.

MR. FRANCIS GODRICH, whose death occurred, as already announced, on the 8th inst., at Fulham-road, West Brompton, at the advanced age of eighty-five years, had been in practice in that neighbourhood for sixty years. For half a century he had been officially connected with St. George's Workhouse, and for nearly the same period he was medical officer of the Brompton District of the Kensington Union, as well as surgeon to the Police for upwards of forty years. He became a Licentiate of the Apothecaries' Society in 1818 and a Member of the Royal College of Surgeons in 1819. He was a life governor and one of the original founders of the Medical Benevolent College at Epsom, one of the founders of the Chelsea Benevolent Society, and for the greater part of his long life took a prominent lead in all the movements for the improvement of the district in which he resided, and of the condition of its inhabitants.

Few men have done more to raise the status of the profession. Of this, one fact may be recorded. In 1834, when called upon to give professional evidence on an inquest, he refused to do so without remuneration; he was threatened with the usual pains and penalties, but persisted; the result being that he was appointed chairman of a committee through which the late Mr. Wakley, M.P., introduced, and carried, in the House of Commons the Medical Witnesses Bill, a measure by which the payments of fees to medical witnesses was rendered compulsory. For many years he devoted special attention to small-pox and revaccination, and was an earnest and persistent opponent to the Fulham Small-pox Hospital; holding the opinion that it was a centre of infection to the immediate neighbourhood surrounding districts. His experience as Medical Officer to the Brompton District, adjacent to the Hospital, led him to this conclusion, and to the decided opinion that the aggregation of large numbers of cases of this disease intensified and extended its area of contagion and its infecting power to a far greater extent than is at present generally supposed; indeed, his death may be attributed in some degree to his advocacy of this opinion, for it was soon after delivering an excellent speech at the Chelsea Vestry Hall on this subject that he was seized with apoplexy, which in less than two days afterwards terminated his long and useful life. His death will be greatly mourned not only by his relatives and friends, but by the inhabitants of the district generally, for his long career was distinguished by kindness and generosity to all—more especially to the poor, to whom he was a true friend.

SAMUEL RICHARDS, M.D.

DR. RICHARDS was born on March 30th, 1808. He was articled to the late Mr. Jarman of Nottingham, and afterwards studied at Guy's Hospital. He commenced practice in Bedford-square, and continued it in the same locality for nearly fifty years. Dr. Richards was associated with the late Mr. Wakley, Dr. Beaman, Dr. Tyler Smith, and others, in the foundation of the New Equitable Life Office, in 1851. This office was established to enforce the principle that medical men should be paid a proper and remunerative fee for their professional opinions of the health and probable longevity of proposed assurers; insisting that the opinion was asked for in the interests of the office, and not of the patient: also that medical men should be regarded as agents, and receive the same consideration in cases sent by them to the offices that is awarded to solicitors. In 1862 the New Equitable was amalgamated with the Briton. It is computed that the profession has received in fees from the New Equitable and the Briton offices over 250,000 guineas.

Dr. Richards suffered from disease of the heart for many years, but his devotion to the profession was such that, in spite of the advice of medical friends, he continued to practise until last June, when failing health obliged him to retire and abandon the hope he so often expressed, that he might "die in harness." He died on March 7th from bronchitis and heart disease, with the usual complications.

Medical News.

CAMBRIDGE UNIVERSITY.—At a special congregation on the 9th inst., the degree of Bachelor of Medicine was conferred on Samuel Nall, St. John's College.

MR. W. F. FULLER, late Assistant Resident Medical Officer of the St. Marylebone Workhouse, has received a superannuation allowance of £80 a year.

THE GLASGOW OPHTHALMIC INSTITUTION.—At the annual meeting of the friends of this charity, it was announced that the subscriptions during the past twelvemonth had been in excess of the year preceding by £199, chiefly derived from workpeople. The hospital is to be extended, by the addition of a storey to the main building and one to the wing in Wellington-street, thus supplying a new operating theatre lighted from the roof. It is proposed to make the consulting physician, acting surgeon, and acting physician *ex officio* members of the Board of Directors.

SANITARY ASSURANCE. — On Tuesday night Professor F. de Chaumont delivered a lecture to a large audience at the London Institution on Sanitary Assurance. Mr. Erichsen, F.R.S., took the chair. The lecturer observed that of the 700,000 deaths per annum recorded by the Registrar-General consumption caused about 70,000; diseases of the respiratory organs, 100,000; diarrhœa, 33,000; enteric fever, 11,000; scarlet fever, 25,000; and diphtheria, 3500. Some of these diseases could be prevented altogether if dwelling-houses were put in a good sanitary state, and others might be modified to a very material extent. These diseases were propagated by foul air and foul water. The lecturer went on to show the fearful extent of mortality and sickness caused by defective sanitary arrangements, and to call attention to the Sanitary Assurance Association which had been formed last November. The object of this association was to inspect the sanitary arrangements of the dwellings of those who chose to become members. When a house was found to be in a proper sanitary condition a certificate would be granted. This work would be carried out under the personal supervision of the appointed officer, who would direct what had to be done, leave it to the occupant of the house to employ, if he chose, his own workpeople, and then, after seeing that the work had been properly done, grant the certificate above referred to. These advantages would be secured by the payment of a small entrance fee and annual subscription. Mr. Erichsen said that the work of the surgeon was materially retarded or aided by the sanitary state of the house in which the patient lay. He cordially approved of the association, and thought it had a large field of usefulness before it. On the motion of Sir Joseph Fayrer, seconded by Mr. Brudenell Carter, a vote of thanks was passed to the lecturer.

THE INTERNATIONAL MEDICAL AND SANITARY EXHIBITION.—The Committee, which met on Tuesday last, made considerable progress in the appointment of judges for the various sections. Among those who have consented to act as judges are, Dr. W. B. Carpenter, C.B., F.R.S., Dr. Garrod, Dr. Bristowe, Dr. Farquharson, M.P., Dr. Playfair, Dr. Buchanan Baxter, Mr. John Marshall, F.R.S., Mr. Critchett, Mr. H. Power, Mr. Tomes, F.R.S., Sir Joseph Fayrer, Mr. C. Heath, Mr. Bryant, Mr. T. Smith, Surgeon-General Longmore, C.B., Major Duncan, R.A., Captain Douglas Galton, C.B., Dr. Thorne Thorne, Professor Prestwich, F.R.S., Mr. Alfred Waterhouse, A.R.A., &c., &c. The Executive Committee of the International Congress have guaranteed £50 towards the guarantee fund (which now amounts to £1026 7*s.*), and it has been arranged that all members of the Congress shall be admitted free to the exhibition. We would remind our readers that the 31st inst. is the last day for making applications for space. It must be remembered that the Exhibition Committee are glad to receive *single articles* for exhibition, and thus scientific inventors will have an opportunity of displaying apparatus, &c., for a fee which is merely nominal. It is hoped, also, that hospital construction and arrangement will be represented, and that the medical officers and managers of public or private institutions will take steps to show ground plans and elevations.

THE FULHAM SMALL-POX HOSPITAL. — "The Times" of the 17th inst. contained the following:—"The Central Committee formed to take steps to prevent the reception of further small-pox patients into the Fulham Hospital has been sitting daily; and sub-committees have now been elected for the Kensington, Fulham, Hammersmith, and Chelsea districts respectively. A resolution has been passed by the Central Committee requesting their chairman, Mr. J. F. B. Firth, M.P., to ask Mr. Dodson, the President of the Local Government Board, to now receive a deputation of a small number of representative inhabitants of the borough of Chelsea on the subject of the spread of small-pox through the cases brought to the Fulham Small-pox Hospital, as the position of affairs is very different from that which existed when the right hon. gentleman was first asked to receive a deputation on account of the decision of the House of Lords in the Hampstead Hospital case, and as the two cases—those of Hampstead and Fulham—are precisely similar. The reply of Mr. Dodson has not yet been given. In the meantime subscriptions to the Guarantee Fund are flowing in to the committee; and it is understood that the latter will at once proceed to move for an injunction to prevent any further new cases being received into the hospital, and to close the same when the epidemic shall have ceased."

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest*

AITCHISON, J., L.R.C.P.Ed., L.R.C.S.Ed., has been reappointed Medical Officer of the Wallsend District of the Tynemouth Union.

ANGELL, Mr. A., has been reappointed Public Analyst for the Borough of Guildford for three years.

BYRNE, E. H., L.M., has been appointed Medical Officer to the High-street Dispensary District, Dublin, vice Peele, deceased.

COX, M. F., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Physician to St. Vincent's Hospital, Dublin, vice Cryon, deceased.

CRAWFORD, C. H., M.D., has been appointed Physician to the Staffordshire General Infirmary.

DAVEY, F. A., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Fifth District of the Royston Union.

EDWARDS, D. T., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Pentyrch District of the Cardiff Union.

FAVELL, R., M.R.C.S.E., L.S.A.L., has been appointed one of the Medical Officers of the Jessop Hospital for Women, Sheffield, vice Dr. E. Jackson, resigned.

HOOPER, E. E., M.R.C.S.E., has been appointed Medical Officer for the Fourth District of the Reigate Union.

JOHNSTON, R., F.R.C.S. & M.R.C.P., has been appointed Medical Officer of Health and District Medical Officer of the Wymondham Division of the Melton Union.

KISBY, G., L.F.P.S.G., L.K.Q.C.P.I., has been appointed to the Seventh District of the Ashton-under-Lyne Union.

LANSDOWN, F. P., M.R.C.S.E., L.S.A.L., has been reappointed Senior Surgeon to the Bristol General Hospital.

LUNDY, L. F., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer and Public Vaccinator for the Sunbury District of the Staines Union.

MOORE, T., F.R.C.S.E., has been appointed Visiting Surgeon to the Seamen's Hospital, vice Davies-Colley, resigned.

NELL, R. F., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Penarth District of the Cardiff Union.

PLUMMER, C. J., M.R.C.S.E., has been appointed Medical Officer for the Fourth District of the Alton Union, vice Woods, resigned.

PYBURN, G. W., B.A., L.R.C.P.L., M.R.C.S.E., has been appointed Surgeon to the Hull, Barnsley, and West Riding Junction Railway and Dock Works.

REID, G., M.B., has been appointed Physician to the Staffordshire General Infirmary.

ROBINSON, A. H., M.D., M.R.C.S.E., has been appointed Surgeon to the Hull, Barnsley, and West Riding Junction Railway and Docks Works.

RUSSELL, W., M.B., has been appointed a Honorary Physician to the Carlisle Dispensary.

SAUL, W. W., M.D., has been appointed Surgeon to the Duke of Lancaster's Own Yeomanry Cavalry, vice Moore, deceased.

SPRAKELING, R. J., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Bootle Urban Sanitary District for one year.

TREHARNE, J. L., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Spottland District of the Cardiff Union.

WALSHAM, W. J., F.R.C.S.E., has been appointed Assistant-Surgeon to St. Bartholomew's Hospital.

WARD, H. D., M.D., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Blythe Urban Sanitary District.

WELCH, J. B., M.B., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Handsworth Urban Sanitary District for the ensuing year.

WILSON, F., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed to the Heighington District of the Darlington Union.

Births, Marriages, and Deaths.

BIRTHS.

BABER.—On the 14th inst., at Langton, near Tunbridge Wells, the wife of Henry Aitkens Baber, M.R.C.S.E., of a daughter.

COLGATE.—On the 3rd inst., at Tresserans, Eastbourne, the wife of Henry Colgate, M.D., F.R.C.S., of a son.

ELLISON.—On the 28th January, at North-terrace, Adelaide, South Australia, the wife of S. K. Ellison, M.R.C.S.E., of a son.

HIND.—On the 12th inst., at 3, Whitehall-place, Stockton-on-Tees, the wife of Henry Hind, F.R.C.S., of a son.

HORMAZDJI.—On the 11th inst., at the General Hospital Branch Dispensary, Cheltenham, the wife of R. N. Hormazdji, M.R.C.S.E. L.R.C.P. (Resident Surgeon), of a son.

MARRIAGES.

CHAPMAN—CRUMP.—On the 9th inst., at St. Margaret's, Westminster, Walter Chapman, F.R.C.S.E., of Lower Tooting, Surrey, to Martha, widow of the late Albert Crump, Esq., of Forest-hill, Kent.

DOUGLAS—FULLER.—On the 26th ult., at St. Andrew's Church, Pittsburg, U.S.A., by the Rev. Reese F. Alsop, Rector, William Douglas, M.D., of Belfast, Ireland, to Anna Marie, youngest daughter of the late Captain S. J. Fuller, H.E.I.C.S., of Canada.

RAE—DUNCOMBE.—On the 8th ult., at Christchurch Cathedral, Nassau, Bahamas, by the Rev. W. H. Strombom, Rural Dean, William Masters Rae, Esq., Surgeon, Royal Navy, R.N. Hospital, Bermuda, to Beatrice de Saussure Kelsall, youngest daughter of the Hon. Frederick Duncombe, M.D., J.P., of Nassau.

DEATHS.

CHEYNE.—On the 6th inst., at Naples, after four days' illness, of acute meningo-encephalitis, George Cheyne, Esq., M.D.Edin., of 5, Bryanston-street, London, formerly of Mexico.

DAVIDSON.—On the 8th inst., at Bexley-road, Erith, Kent, James Davidson, M.D., M.R.C.P.L., Retired Fleet-Surgeon, R.N., aged 63.

STACY.—On the 12th inst., John Edward Stacy, F.R.C.S.E., of Cavendish-road, Brondesbury, in his 82nd year.

THORNTON.—On the 4th inst., suddenly, at his residence, Bank Lodge, Scarborough, William Henry Thornton, M.D., F.R.C.S.E., J.P., deeply regretted.

WILSON.—On the 4th inst., suddenly, at 9, Woodside-crescent, Glasgow, James George Wilson, M.D., F.R.S.E., F.R.C.S.E.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, March 21.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Professor Henry Trentham Butlin, "On the Relations of Sarcoma to Carcinoma."

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—5 P.M. Dr. Julius Althaus, "On the Physiology and Pathology of the Olfactory Nerve."

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Spencer Watson, "On Unusual Affection of the Nose."—Dr. Wynn Williams, "On a Case of Rupture of the Perineum in a Child."—Dr. Gilbart Smith will exhibit a Specimen of Endocarditis with Embolism.

Tuesday, March 22.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

ROYAL INSTITUTION.—3 P.M. Professor Edward A. Schäfer, "On the Blood."

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8 P.M. Ordinary Meeting.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. C. Higgens, "On a Case of Vascular Protrusion of the Eyeball."—Mr. C. T. Dent, "On a Case of Innominate Aneurism treated by simultaneous Distal Ligature of the Carotid and Subclavian Arteries, with remarks on the behaviour of a Tendon Ligature."

Wednesday, March 23.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Professor Henry Trentham Butlin, "On the Relations of Sarcoma to Carcinoma."

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Croonian Lectures: Dr. Moxon, "On the Influence of the Circulation upon the Nervous System."

HUNTERIAN SOCIETY.—8 P.M. Adjourned Discussion on Dr. Herman's Paper ("Prolapse of the Ovaries").—Mr. McCarthy and Mr. James E. Adams, "On Cases of Varicocele treated by Excision."

Thursday, March 24.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND SCIENCES.—Professor John Perry, "On the Future Development of Electrical Appliances."

ROYAL INSTITUTION.—3 P.M. Mr. H. H. Statham, "On Ornament."

Friday, March 25.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Professor F. Treves, "On the Pathology of Scrofulous Affections of Lymphatic Glands."

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Croonian Lectures: Dr. Moxon, "On the Influence of the Circulation upon the Nervous System."

ROYAL INSTITUTION.—8 P.M. Mr. A. Buchan, "On Weather and Health of London."

QUEKETT MICROSCOPICAL CLUB.—8 P.M. Mr. J. G. Waller, "On Cliona Celata: Does the Sponge make 'the Burrows?'"

CLINICAL SOCIETY OF LONDON.—8½ P.M. Mr. J. R. A. Douglas, "On Cases of Varix treated by a new Instrument for Obliterating the Veins.—Dr. Whipham and Mr. Rick, "On a Case of Extirpation of the Larynx.—Mr. Spencer Watson, "On a Case of Intra-Cranial Disease involving several Cranial Nerves."—Dr. B. O'Connor, "On a Case of Syphilitic Psoriasis."

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND SCIENCES.—Sir George Campbell, "On the Tenure and Cultivation of Land in India."

Saturday, March 26.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Rev. H. R. Haweis, "On American Humorists."

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

PRELIMINARY EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

IN answer to a large number of perplexed correspondents who have written to us respecting the preliminary examinations at the Royal College of Surgeons, we reproduce the subjoined official notice, dated January 13th, 1881:—

"Notice is hereby given that from and after the 31st December, 1881 the preliminary examinations for the diploma of member and of fellow of this College, at present conducted by the College of Preceptors under the authority of the College, will cease, and that, from and after the date of this notice, candidates for the diploma of Fellow will not be required to undergo any preliminary examination beyond that required for the diploma of member of the College."

MORBIFIC ODOURS.

To the Editor of THE LANCET.

SIR,—Taking a broad and therefore perhaps the only useful view of zymotic complaints, surely there can be no reason to puzzle oneself for an explanation of the phenomena mentioned by Mr. Bernard—at least, presuming the period of incubation in small-pox to be longer than a few days, the one word coincidence seems to me to be explanation enough. For example, my experience would tend to show that a day or two before a good honest "cold in the head" appears in its open form a state of exaltation or tension of the nervous system is usually felt, in which state one might easily imagine an extra keen sense of smell to exist.

Exposure to a draught or chill may be said to be the immediate or direct cause of a cold, but surely the proper view is that it acts merely as the "last straw," added to the pre-existing load, and if there is any point at all in that well-known saying about the camel's back, it lies in our attention being drawn to the heavy load, which, without the last straw, might have escaped our notice altogether. The period of incubation in all zymotic complaints is probably of much longer duration than we are apt to imagine, and unless we have faith to believe it, we might frequently be puzzled by such like coincidences as Mr. Bernard narrates.

I remain, Sir, yours obediently,

March 14th, 1881. F. ORTON, M.D.

To the Editor of THE LANCET.

SIR,—With reference to Mr. Alfred Bernard's letter in a recent number of THE LANCET, will you allow me to say that I have a large number of cases of variola coming to my notice, and having been accustomed to make careful notes of each case, can assure Mr. Bernard that the peculiar smell followed by the disease is of by no means an uncommon occurrence.

I am, Sir, yours, &c.,

March 14th, 1881. J. B. M.

CENSURE OF A MEDICAL MAN BY THE HONITON BOARD OF GUARDIANS.

WE share with Dr. Pullin regret that the patient was not seen earlier, but this partly arose from an insufficient message as to the nature and needs of the case. It is a pity that the criticism of the Board could not have been extended from the conduct of the medical man to the state of the cottages in which the poor man lived—and died. They are thus described by Dr. Pullin:—"During the first eight days of his illness he was living in a house under repair, in the walls of which were partially covered holes large enough for his child of ten to crawl through, and through which the cold—unprecedented during this century—of course freely entered, and his bedclothing was very limited. Late in the evening of the eighth day he moved—himself walking through the snow—to another house under repair, which had not been occupied for several weeks, and which was, I am informed, wet from top to bottom." It is lamentable to think of such cottages in connexion with the snow storms of January.

"COTTAGE HOSPITALS."

To the Editor of THE LANCET.

SIR,—It is stated in THE LANCET of Saturday last that at a meeting held at Chelmsford for the purpose of promoting the establishment of a cottage hospital there, Dr. Vipan said out of 260 cottage hospitals which had been founded in Great Britain only eight had failed, and those not from want of funds, but on account of theological disputes between members of rival sects. I almost fancy Dr. Vipan must have been imperfectly reported, as so far is the statement in question from being accurate that I have shown in my book on Cottage Hospitals, by giving the history of all the failures, that in only one instance—that of the Wrington Hospital—has there been anything approaching a religious difficulty. The secretary of this hospital was a Dissenter, and to ensure that all the patients should be sent to chapel and not to church, he bought the cottage hospital, and it was soon after closed. In speaking of the chaplains and religious services, I state, as the result of careful inquiry, "so admirably has the feeling of simple piety which animated the early promoters of this movement descended upon their successors and followers everywhere, that sectarian bitterness is entirely unknown to the managers of these little hospitals."

The point at issue is all-important just now to hospital managers generally, and so I venture to ask you to allow me to make this correction.

I am, Sir, yours, &c.,

Gloucester-road, Regent's-park, N.W., HENRY C. BURDETT.
March 14th, 1881.

Club.—It is a point of law, but a stamped receipt for any sum over £2 is necessary.

Dr. Duffey (Dublin).—In an early number.

Enquirens.—18 and 20, Kentish-town-road.

Mr. F. G. Taylor.—The case seems a hard one, but it is a question of arrangement between employer and employed.

Mr. Lane's communication will appear in our next.

Country Practitioner.—1. Barnes or Galabin.—2. Tilbury Fox, Liveing, or Duhring.

Mr. George Moule Evans.—A medical officer has no legal right to question the "order" for "medical relief" given in any case, and it is unwise for him to do so. It would have been prudent to write to the clerk of the Board of Guardians, not to the overseers, and nothing should have been said to the patient. The case had better not be followed up. It is most desirable to avoid the sort of conflict these cases occasion.

"THE CASE OF PROBABLE POISONING BY COLCHICUM."

To the Editor of THE LANCET.

SIR,—From the report of this case, published by Dr. C. Budd in your issue of the 5th inst., I quote the following passage:—"To these symptoms were now added constant twitchings of the muscles, greatly aggravated by any movement." It has probably occurred to many persons who have read this that the exact time at which this peculiar and characteristic feature commenced is indefinitely fixed by Dr. Budd. The account in this respect, therefore, is misleading, for on this the whole gist of the case lies. It was clearly ascertained that the gentleman could have taken no pills after Sept. 2nd. The convulsive twitchings of the muscles commenced on the evening of the 17th. On the afternoon of that day he transacted business, and executed some mining setts. His lawyer confirms me in declaring that at that time he was perfectly steady and free from twitchings. Thus fourteen clear days elapsed before the distinctive symptom of the influence of colchicum arose, with persistent vomiting and diarrhœa during all the time. In these circumstances I was unable to concur with Dr. Budd in his diagnosis, preferring to regard this remarkable case as one due to blood poisoning from suppressed gout, in the causation of which it is probable that the colchicum acted only as a factor.

I am, Sir, your obedient servant,

Holsworthy, March 14th, 1881. LINNINGTON ASH, M.R.C.S.E.

HYGIENIC INFLUENCE OF HOUSE PLANTS.

DR. ELY M'CLELLAN contributes to the *Philadelphia Medical Times* a note on the hygienic influence which may be exerted by house plants on individuals who are predisposed to phthisis pulmonalis. The writer has observed a case which he considers to be thoroughly corroborative of the view advanced by Dr. Anders—viz., that breathing continuously the atmosphere of apartments in which plants are kept tends to retard the progress of pulmonary consumption. The case was that of a young man whose mother died of phthisis at a comparatively early age, leaving a family of five children, four of whom were carried off by the same disease. The survivor, the young man in question, married at twenty-three, and was accustomed to complain of weakness of the chest and constant liability to take cold. Being an enthusiastic floriculturist, he stocked his bedroom and sitting-room with plants, and his health appears to have become highly satisfactory, if not robust.

Mr. C. B. Grant.—Dr. Richet's paper in THE LANCET of Jan. 1st and 8th of the present year may perhaps assist our correspondent.

Mr. J. C. Orchard.—Our Students' Number, published on Sept. 12th last, will give the information required.

N.—Our correspondent's ordinary medical attendant would be the best person to consult on the subject.

Mr. Joseph Miller.—The report was doubtless rather fuller than is usual of medical details, but having been given at the inquest, we do not see much reason to complain of their publication.

DESQUAMATION AND INFECTION IN SCARLET FEVER.

To the Editor of THE LANCET.

SIR,—Allow me to remark on this subject that I consider the "Medical Attendant at the College" referred to, by isolating the boy for three weeks, did all that was necessary, as far as quarantine was concerned, to prevent the spread of infection.

It is certainly not my experience that desquamation is delayed in mild cases of scarlet fever. I find it always follows on the disappearance of the rash, though frequently in so minute a form as to be passed unnoticed. I have met with a few mild cases where, after the shedding of this almost invisible epidermic dust, an unusual interval elapsed, and then the thicker epidermis of the palms of the hands and the soles of the feet began to chip and peel. In two cases—both consumptive lads—this interval was nearly five weeks. I did not regard this late desquamation of these parts as infectious, nor did it prove so.

I may also observe that the best quarantine for scarlet fever is the inunction of carbolic oil (1 to 40). It is invaluable used twice a day for at least two weeks in mild cases. These cases, compared with severe cases, are much more infectious, owing to the liberty they often have, and the extreme minuteness of the infectious scales which the inunction restrains from being scattered about.

I am, Sir, yours faithfully,

Sudbury, Suffolk, March, 1881. J. SINCLAIR HOLDEN, M.D.

Mr. Thos. Holland will find, on reference to the Medical Directory for 1881, that the proper initials are appended to the name mentioned.

Mr. Richard Barker.—We must adhere to our rule.

Inquirer.—Information may be obtained from our advertising columns.

Mr. Mark Long.—D. Bogue, St. Martin's-place, London.

ARE MEDICAL MEN LIABLE TO ATTEND WHEN SENT FOR?

AN inquest was held last week in Dublin on the body of a dockmaster, who was killed by falling into the Spencer Dock. According to the evidence, as reported in the daily papers, it appears that the sister of the deceased went immediately, accompanied by a policeman, to the nearest dispensary, but the medical officer there refused to attend unless a fee of five guineas was paid. Another practitioner, however, attended at once without any stipulation as regarded a fee; but death resulted before he arrived. The jury censured in strong terms the conduct of the medical practitioner who had refused to attend the deceased, and commended the conduct of the gentleman who promptly went when summoned by the relatives. We think that in cases of accident or emergency a medical man should have very good reasons indeed for declining to attend. The public are sometimes shocked at a medical man for refusing to respond to an urgent message; they would be more shocked still if they knew how often the prompt and self-denying attendance of the medical man is never recompensed or even recognised.

Enquirer.—There is no such account in any single volume or pamphlet. Our correspondent should get the reports of some of the best provident dispensaries, as that of Northampton, Haverstock-hill, &c., and the publications of the Metropolitan Charity Organisation Society on the subject.

SILKWORM GUT.

Chirurgeon suggests the use of silkworm gut as an absorbable ligature in tying of arteries.

F. P. F.—We do not know of an institution of the kind.

Delta.—The reply will be found in our last issue, page 442.

A PLEA FOR PRESCRIBING CHEMISTS.

To the Editor of THE LANCET.

SIR,—The article in THE LANCET of Feb. 26th on the "Wrongs of Counter-practice" is sternly severe, but not more severe than just. The druggist who professes a knowledge of diseases and their treatment you characterise as a "quack," in other words as a dishonest pretender There is no escape from the correctness of such a verdict. The prescribing chemist who honestly examines his own conduct cannot but be self-accused and self-condemned.

The moralist who looks at this subject will find much food for reflection. In England there are probably more than thirty thousand qualified chemists and druggists, the greater part of whom you say treat disease — that is, affect a knowledge which they do not possess.

This behaviour on the part of a whole class is of more than passing interest, and particularly to chemists themselves. If they were uninstructed they might be expected to have confused ideas of morality, especially if self-interest were the confusing element, but they will hardly care to escape the condemnation due to their moral obliquity by pleading ignorance of the very elements of morals. A man need not be a philosopher to understand that it is a knavish thing to profess to know that which he does not know, and still more knavish when this is done for the purpose of gaining money. Gipsies and others who tell the fortunes of maidservants for reward are sent to prison. What is the moral difference between a gipsy who professes to know the future and a chemist who professes to understand disease?

But though the case against prescribing chemists is so clear, it canno. be said that they are absolutely without defence. Their defence, as is well known, is a countercharge against medical men. They say that "medical men add the calling of a druggist to that of a physician, and as long as doctors continue to be druggists so long will druggists continue to be doctors." This is their position, and they hold it with obstinate tenacity. It is easy to see, of course, that there is no real reason in this position. A medical man who diagnoses a disease and orders suitable drugs for its treatment may surely put them into a bottle with water in a competent fashion, but it does not therefore follow that another man who may be well qualified to put drugs into a bottle with water is able also to diagnose and treat disease. The doctor includes the druggist as "the greater includes the less," but the druggist by no means also includes the doctor—no one ever affirms that "the less includes the greater."

But though in strict logic the druggist, metaphorically speaking, "has not a leg to stand upon," in the region of practical everyday ethics his case is in no sense so desperate. Let a well-spoken chemist plead his cause before a jury of his countrymen, and he will have little difficulty in obtaining a verdict of "Justifiable Retaliation." It is in the sphere of everyday morals that this problem must be solved. Shall the druggist continue to prescribe? This question is really the equivalent of another—viz., Shall the doctor continue to dispense? In discussing this latter proposition we do not enter upon a question of morals, but of expediency. The doctor's right to dispense has not been denied, nor even doubted; but, granting that it is strictly and logically right for the doctor to dispense, is it expedient? Is it not highly inexpedient—so inexpedient that, from the point of view of the druggist and the thinking part of the public, it is practically indefensible?

The one party or the other must clearly give way. Whether of the two shall it be? It will be honourable to the druggist to desist from prescribing, because he will thereby purge himself of an offence; but it will be far more honourable to the doctor to leave off dispensing, because he will thereby sacrifice an acknowledged right in order that he may perform an act of wise self-abnegation.

I will not now enter upon a discussion concerning the practicability of giving up the dispensing of medicines entirely to chemists and druggists. A few questions, however, may be offered for consideration. Firstly, what is the real function of the modern medical man? Is it not the diagnosis and treatment of disease? Secondly, what is the true function of the modern druggist? Is it not the preparation and dispensing of medicines? If this be not his function, what is? As was the old apothecary, so is the modern chemist—"Ye doctor's cooke." Do the medical men of the present time wish to be apothecaries, or do they desire to be physicians? If family doctors prefer to be apothecaries, by all means let them continue to dispense and continue to wrangle with the rival apothecaries at the chemists' shops; but if they wish to see their profession advanced in true dignity and efficiency, let them cast away this miserable relic of earlier and more ignorant times, and stand forth in their true character as physicians. If this be done, they may, with an honest conscience and a fearless front, demand the absolute suppression of "counter-practice."

I am, Sir, yours, &c.,

Grosvenor-road, N., Feb., 1881. GEO. W. POTTER, M.D. Edin.

THE CASE OF ACCIDENTAL POISONING BY MORPHIA AT THE LONDON HOSPITAL.

To the Editor of THE LANCET.

SIR,—In the report of the inquest upon a case of accidental morphia poisoning, held at the London Hospital on the 28th ult., which appears in your issue of last Saturday, an important error occurs. It is stated in your report that the strength of the lotion sent from the dispensary was only half as strong again as that prescribed. Had this been the case the mistake of the dispenser would probably have been unimportant, as a lotion containing two grains of morphia to the ounce would under the circumstances have been almost as certainly fatal as that actually used. The substitution of a drachm of morphia hydrochlorate for a drachm of the pharmacopœial solution formed a lotion containing 120 times as much morphia as was ordered.

The case was one of pemphigus of rather an acute form, which dated from three weeks prior to admission, and was under treatment in the hospital about a fortnight. The patient was a cachectic female, aged fifty. There was an extensive area on the trunk, raw or covered with thin flaky crusts of secretion in a condition very favourable to absorption, and only a small quantity of morphia was therefore ordered to be added to the lotion to allay the irritation complained of. It was found that about six ounces of the lotion were used in four applications, which would thus have contained four and a half grains of morphia each, making a total of eighteen grains applied within a period of twelve hours. It is remarkable that no symptoms of narcotism were noticed until about four hours before death. The house-physician was called to see her about 8.45 A.M., and found her deeply comatose. He had been summoned to see her an hour previously on account of some twitching in her face, which it was thought might indicate the approach of a fit. She was then noticed to be pale and cold, and rather strange in her manner. This was less noticeable on account of the patient being nearly stone deaf. She then sat up and drank some brandy. At 6 A.M. she had washed herself and attended to her toilet as usual, complaining only of some headache, and of not feeling so well. During the night she had snored much, but not more than usual. The application of the lotion had commenced from about 9 P.M. the previous evening. The patient died at 12.15 in the afternoon, or about fifteen hours after the first application of the lotion. Injections of atropine were given subcutaneously amongst other measures adopted in the endeavours to resuscitate the patient. Three injections of one-eighth of a grain were given, and finally one-fourth of a grain, with the effect of dilating the pupils, the left more so than the right, but without any effect on the coma.

Such unfortunate occurrences as this would happily appear to be rare. In the tabular collection of cases of opium and morphia poisoning in the Manual of Jurisprudence of Woodman and Tidy only two cases are included in which death resulted from the external application of these drugs: one in which death occurred ten hours after the application of thirty grains of morphia to an open ulcer of the breast (Taylor, vol. i., p. 358), and the other the case of a young man who applied a large quantity of laudanum on a poultice to the abdomen on account of a slight ailment with pain in that part (Stillé, Mat. Med., vol. i., p. 714).

An accident of this painful nature suggests the question whether it would not be desirable to discontinue the use of identical symbols for measurement of both fluids and solids. The introduction of the letters "fl." before the symbols when used for fluids, as involving more trouble, would always be liable to be omitted when unnecessary, and hence also when such a precaution might prevent a fatal error. The distinctive symbols of fluid measures might, however, be indicated without any additional trouble by writing them with a rounded summit, the corresponding symbols for measurement of solids being written with a straight line at the top.—I am, Sir, yours, faithfully,

Finsbury-square, March 9th, 1881. F. C. TURNER.

ENTHETIC DISEASE IN THE UNITED STATES.

OF the boys who were applicants for enlistment as apprentices in the United States navy during 1879 (says the *Boston Medical and Surgical Journal*) twenty per thousand were rejected on account of venereal disease, twelve of these being syphilitics.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

Croonian Lectures

ON THE

INFLUENCE OF THE CIRCULATION ON THE NERVOUS SYSTEM.

Delivered before the Royal College of Physicians of London,

BY WALTER MOXON, M.D. LOND., F.R.C.P.

LECTURE I.—PART I.

MR. PRESIDENT AND GENTLEMEN,—An essay might well be written on the consequences to Medicine of the rise and expansion of the science of Biology; to show how it affects medical study that the physiology of man has become a special branch of a physiology of living things. This is not the occasion for such an essay, nor even for such a remark; but the remark arises because, in beginning these lectures on the behaviour of the human brain under varying states of the circulation of the blood within it, I was of course induced, as a first step, to bring forward the natural history of the subject. But when I referred to the excellent and ably written text-book which is now universally employed as a students' manual in physiology, and searched in it for the physiology of the circulation in the human skull, I did not find a word upon the subject. I found a full and very interesting account of the tailing off of ranine intelligence which reveals itself when the several parts of the brain of a frog are successively cut away; but no notice of the curious and very important mechanism whereby the human brain is made secure within the skull under the varying stress of blood-pressure that accompanies bodily or mental exertion. I observed that the biological physiologist regards the human brain as at one with the vertebrate brain—a general kind of thing more easily studied in the frog, the dog, or the monkey, on account of its simpler development in these animals. The biologist thus takes vertebrate brains at large, and it appears that to him the blood-supply of the human brain is a detail respecting one kind of brain only, and he cares nothing for its congestion, and giddiness, and insensibility—such particulars are lost sight of in the large scope of biological science. For biology tends to wideness of scope and generality of principle. Indeed, it appears not to be quite happy far out of sight of protoplasm; it goes back to protoplasm to trace up the general nervous system, and says nothing about the cerebro-spinal fluid. But it cannot be conducive to clearness of medical thought upon the circulation in the brain that protoplasm should have displaced the cerebro-spinal fluid from works in which medical students learn Human Physiology. It is not as though protoplasm were better founded than the cerebro-spinal fluid. It is not so well founded; for there can be no doubt that there is such a thing as the cerebro-spinal fluid; nor is there any doubt that it fulfils vitally important functions which greatly concern those who are called upon to be clear about the causes of giddiness or insensibility. But it is by no means certain that there is such a thing as protoplasm. The biologist reduces the various behaviour of the nervous system to what is called the irritability of what is called protoplasm. He regards protoplasm with the same undoubting confidence in its reality as the physical philosopher has in the reality of motion, when he on his part reduces all kinds of activity in unliving matter to terms of what he calls motion, so that heat is a mode of motion, electricity a mode of motion, and light a mode of motion. Other philosophers, less restrained by fixation in the science either of living or unliving matter, generalise one sweep more widely, and tell us that vital motion is a mode of motion; so that we may take out all things knowable, even to human thought, in terms of motion, much in the same way as all kinds of value, even to human motive, might be taken out in terms of pence. But of course it is true that just in the same way that all kinds of value may equally rightly be taken out in terms of shillings or of pounds as in pence. And just in the same way as all kinds of activity in unliving matter might equally well be taken out in terms of electricity or in terms of light, as in terms of what is called motion. So also the behaviour of living matter may as rightly be taken out in terms of the brain cell or of blood as in terms of what is called protoplasm; for the only basis of knowledge in all these systems is equivalence in convertibility. The capitalist knows that his pound is convertible into so many shillings, or may be expressed in terms of shillings; the physical philosopher that his foot ton is convertible to so much electricity, or may be expressed in terms of electricity; and the biologist thinks that the nerve-cell is convertible to so much protoplasm, or may be expressed in terms of protoplasm. And the other philosopher, less restrained by fixation in the science either of living or unliving matter, thinks he knows that vital motion, even to human thought, is convertible to so much motion.

Meantime the physical philosophers have been led to say that heat is a mode of motion only because mechanical motion is more universally appreciated by our senses, so that it is natural to employ it as a standard. And for all we know the higher animals in the planet Jupiter may be so organised that they obtain mechanical motion only by difficult experiments, as we do electricity, whilst in their hot region they have electricity always obvious to their senses. In which case we may depend upon it they would naturally say mechanical motion is a mode of electricity. For there is no sense of reality in which electricity is not as real as mechanical motion, and it would be quite as right to adopt electricity as the standard, and say motion is a mode of electricity. In fact, electricity reveals the nature of motion, and motion reveals the nature of electricity. They mutually reveal their common nature: under certain conditions the one becomes the other. And the physical philosopher, for purposes of exposition, chooses mechanical motion, because it is the most tangible and the best known, and adopts it as the common standard for his reference and the basis of his thought and reasoning. But the biologist in his field reverses this plain method of dealing, and makes his thought and reasoning rest on protoplasm, which is not the most tangible and the best known of the things he deals with. Indeed, it is so far from being so, that it does not exist at all. There is no such thing as protoplasm. I have watched what is called protoplasm in what are its most nearly pure forms at work, and it was plain that its properties depended altogether on whose protoplasm it was, and that when anything is to be done with it or by it, you must accept it with its own peculiar powers as it is at work before you, and that if you act towards any living thing in terms of protoplasm with the idea of in that way getting a product of its life and nature, you find you have got hold of the wrong end of the stick, and that your abstract idea of protoplasm does not fit to the vital faculty which acts in, and I may say *is*, the living thing.

And whereas every living thing or part of a thing is held by the biologist to be a specialisation of protoplasm in the same way as light and galvanism are held to be specialisations of motion by the physical philosopher, there is no parallel at all in the sureness of the tenets in the two cases; for although motion considered apart from any moving thing is an abstraction like protoplasm, yet it is a simple abstraction which we can use in calculation and verify our calculated results by experiment. But protoplasm is a very complex abstraction, theoretically endowed with all the properties of living matter, and there are no means of testing how far this complex of properties when worked out theorectically in combination with other simple abstractions, like mass, velocity, &c., would be found on experiments to correspond with the calculated result, so that the conception of protoplasm has no stable basis like that of motion. And by means of it we do not get any established ground wherefrom to consider the phenomena of life, and we only spin out speculations by means of it, which when finished are no more realisable than the hypothetical conception with which they begin. Therefore I don't think it any real gain that the biological teacher of the medical student has displaced the cerebro-spinal fluid with protoplasm. And I am begging you to fix your attention particularly on this fluid, because it is upon this fluid that a great deal of what I have to say to-day centres itself.

It has long been known that the watery fluid within the ventricles of the brain finds entry and exit from the brain into the spinal canal, so that it comes and goes from spine to brain according as the pressure of blood in the brain is less or more; and in this way there is provision for a change in the quantity of blood which can circulate in the brain. The degree in which the nervous system can exercise its special power, independently of direct action of its supplying vessels, is a question very important for the obtaining of clear views upon the complicated phenomena of nervous disorders. In these lectures I am going to endeavour to estimate the extent of disturbance of the nervous system which can be fairly ascribed to changes in the calibre of the bloodvessels and in the blood-pressure within them, so as to ascertain what is the true value of the term "congestion of the brain," and to show the relation of the epileptic fit to vascular action, and of angina pectoris to high tension within the vessels. This kind of question has been a great deal lost sight of by the pure physiologist, who seems to me, if I may humbly say so, to have let pass the consideration of some most interesting and important branches of specially human physiology in the modern pursuit of fundamental vertebrate life in that convenient victim and martyr, the common frog. I am now concerned with one such branch, and it is the study of the means whereby the circulation in the human brain is made secure, so that no augmentation of pressure in the brain—either from changes in the force of the heart, or from changes in the atmospheric pressure, or from changes of posture—ever produces any ill effect. Our best modern text-book on physiology scarcely deigns to notice the group of mechanical contrivances whereby the human frame is adapted to go upright. The text-books of twenty years ago used to set forth the several points in the human organism whereby the erect posture is made possible. Dr. Carpenter used to give a list of these, which I will not recount, but only mention that he left out one essential to the erect posture in man—necessary at least to his long maintenance of it—and that is, the ambition that induced him to get upon his legs. Now, for this a relative increase in the size of his brain was required; so that after vitalising and giving energy to brace up all Dr. Carpenter's mechanisms, there might be left enough nervous power to be willing to take the trouble to be upright. But this increased size of brain necessitated an increase of blood supply; a great increase it must be, considering how richly blood is given to nerve.

Meantime the same erect posture placed the brain so much aloft that blood supply to it is less easy. For consider the difference in hæmostatic conditions which arises when a column five or six feet long containing fluid is suddenly raised to the vertical or suddenly lowered to the horizontal position. Imitate the case with a model of some spongy material soaked in liquid, and, of course, as you raise the column of sponge the liquid in it will collect below, and as you lower the column the liquid will go to both ends equally. And, of course, it need not be said that the physical forces which act in dead matter act equally in living, so that this tendency of the blood in the living sponge which composes our frame has to be met and counteracted or all the mechanism for the erect posture would be of no avail.

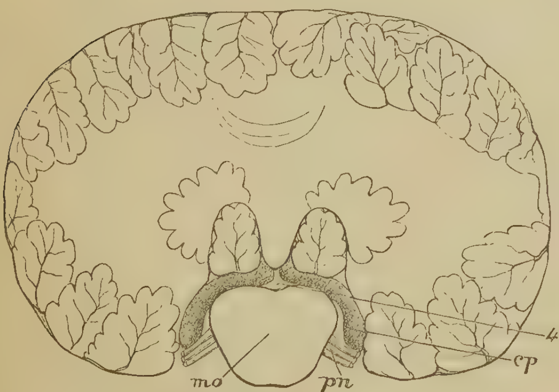
The problem, then, is how to prevent the sinking down of blood from the brain. That there is risk of at least inconvenience from such mere opposition of gravitation to circulation is experienced very often by many persons in delicate health, who suffer a certain giddiness on rising from a stooping posture; a giddiness which may be accompanied by slight loss of sight. But this occasional and trivial inconvenience to some would of course be constant in all, unless there were provided a large means of checking the great tendency of the blood to act in obedience to hydrostatic laws and sink to the lowest possible level. The principal means whereby this is accomplished is doubtless the suction exerted by the practically closed cavity of the skull. Allowing all the considerations which render this cavity less securely closed than a metal globe pierced only for entry and exit of to-and-fro pipes would be, the cranium nevertheless composes a very large space inaccessible to external pressure, except, firstly, by means of the blood in the vessels which enter and leave it, and, secondly, by means of the cerebro-spinal fluid. Let us remember the relatively not very large amount of this fluid in a healthy brain, and we must allow that blood within the skull is to a very large extent prevented from leaving the skull by the impossibility of air or any other substance than blood finding its way in to supply the place of the blood that would go out; and doubtless no part of the whole system of contrivance is equal in its efficiency to this suction. But whilst it is true that by far the greatest part of the blood would thus be retained by suction in the brain, it is also true that the incompletenesses of the closure of the cranium do allow some amount of variation in the quantity of blood which it can hold. This variation is chiefly allowed by the variation in the amount of the watery liquid in the ventricles.

Now the part of the cerebro-spinal fluid which is within the cranium amounts in most persons to about two to three ounces, and it is to a large extent capable of being pushed out of the cranium, or drawn into it. This gives us a variable margin of sufficient importance to call for arrangements that may meet such sudden changes in the amount of blood as would arise in virtue of variations in this fluid. For though it may seem that three ounces do not amount to much when compared with the whole capacity of the skull, yet there is evidence that the quantity of blood in the cranium is only capable of small changes, and that not very large changes of quantity of contents in the skull are required to produce fatal symptoms. I used to weigh the amount of blood which had escaped into the brain in cases of apoplexy, and I never met with more than three ounces and a half of it. This had been sufficient to take away sense and life—that is, so far as quantity is concerned. When the tendency was to a greater bleeding, this showed itself in density or hardness of the clot, not in increase of it. In fact, there was no room for more, and the three ounces and a half correspond nearly with the three ounces of cerebro-spinal liquid, especially when we observe that apoplexy occurs in anæmic brains, in which the cerebro-spinal fluid is present in more than the natural quantity. That apoplexy occurs in anæmic brains I shall prove in my second lecture. Thus an amount of change in the contents, which bears but a small proportion to the whole capacity of the cranium, estimating this at about fifty-five ounces, is all that is observed in case of fatal pressure on the brain. It is true that somewhat more of extraneous substance can be introduced gradually into the cranium without destroying mental life. Thus I have weighed tubercle to the extent of five ounces from the brain of a child, who showed intelligence up to the time of a fatal meningitis, which had come on in consequence of the tubercle. But it is certain that a change of about three ounces is all that can be borne suddenly by the brain. And common movements of the frame must be supposed to be quite equal to produce a change of that extent. For when a person rises suddenly from the stooping posture the blood, which was favoured by gravitation in its flow towards the brain when the head was down, has now to run up to the brain through narrow pipes of bloodvessels, and against friction and gravitation. But if the circulation is feeble the pressure of blood towards the cranium may be deficient. One may estimate the great and important extent to which sudden uprising tends to reduce blood-pressure towards the brain by recalling how raising the arms will impair the power of circulation towards the hands, and how raising the legs will reduce the circulation towards the feet, facts of which the practitioner avails himself in checking hæmorrhage and in reducing inflammation or ulceration of the extremities. And it is well known that a person may even be led to feel faint by raising both arms for a long period. Now, the brain is being constantly put into the position of a raised arm or leg, and although by the suction I have referred to it is kept from such extreme changes as the hand or foot undergoes, yet the cerebro-spinal fluid allows of changes to the amount of about three ounces. But the way by which this watery liquid enters the cranium and brain is, as I shall show, a wider and freer passage, whilst the way in which the blood reaches the texture of the brain is by the narrow passages of the capillary arteries, and if the circulation is feeble, the heart may drive the blood less forcibly to the texture of the brain than the venous pressure in the spinal canal drives the cerebro-spinal fluid into its cavities. So that when the head is raised and the venous blood falls away more readily from within the skull, the cerebro-spinal water may outstrip the arterial blood in the race to supply the place. And thus the ventricles of the brain may tend to fill with water more quickly than the substance of it with blood, and so the brain blanches and the person feels giddy. And this is especially the case when a permanent anæmia of the brain has led to an increase in the capacity of the ventricles of the brain. Many elderly people with poor circulations feel more or less giddiness during a large part of the day from this cause, and if the circulation has become, through age and high arterial tension, very inefficient, every oscillation of the head, even in ordinary walking, will, if the heart's power is at the time rather lower than usual, keep the person distressed with giddiness or a sense of insecurity, which makes him justly rather afraid of apoplexy, but which is a sign of anæmia of the brain. Apoplexy, however, occurs in anæmic brains.

This kind of giddiness, which is characteristic of age with its failing circulation, would keep the human race on all fours during the whole of existence if it were not for certain beautiful automatic mechanisms which tend on the one hand to automatically diminish outflow of blood from the brain, and on the other hand to automatically diminish entry of blood into the brain, so as to automatically keep the brain under all conditions at a certain state of pressure of blood. These mechanisms depend on elasticity of artery and general goodness of venous circulation, and it is the failure of elasticity of artery and the increasing lack of free venous circulation which cause giddiness so readily to appear in old age.

First, as to the mechanism whereby the entry of blood into the brain is automatically checked. For this end it is necessary that means of lowering the rapidity and force of the current in the vessels should be found. Now, the researches of physiologists have shown of late years that there is such a relation between blood pressure and the heart's action that they must infer the existence of a self-acting mechanism, which tends to preserve at a certain level the pressure of the blood. The seat of this mechanism is traced by experiment to the neighbourhood of the origin of the pneumogastric nerves. This inferential mechanism is doubtless the more fundamental and effectual of the automatic means of checking excessive entry of blood into the cranium. But anatomists have hitherto overlooked a very interesting mechanism in the human brain, which must plainly tend to check excessive entry of blood, and which, although not the most fundamental, let alone the chief or only means of automatically checking entry of blood, yet I think must be seen as a superadded contrivance necessitated by the large development of the brain in man, and the consequently large volume, and large change of volume, of blood to be provided for. I refer to the mass of choroid plexus of the fourth ventricle, which stretches down round the side of the medulla oblongata enclosed in the lateral offset of the ventricle, which I will call its *cornu*. Our anatomical works all speak of a sort of pouch from the side of the fourth ventricle, but none of them point out that this pouch is stuffed very full of tufts of bloodvessel in the form of choroid plexus. The cornu, as we will, if you please, call it, reaches down to, and presses upon, the pneumogastric nerve-roots.

FIG. 1.



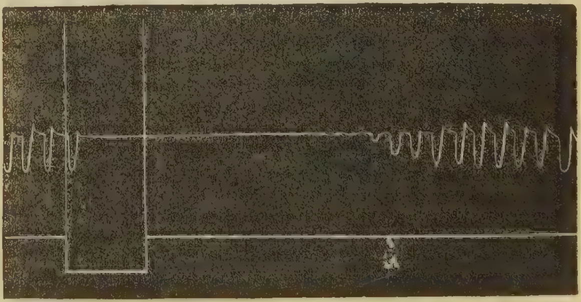
Vertical transverse section of cerebellum and medulla oblongata, through fourth ventricle opposite the origin of pneumogastric nerves, showing: *m o*, medulla oblongata; *4 v*, fourth ventricle; *p n*, pneumogastric nerve; *c p*, choroid plexus.

I said the cornu of the fourth ventricle presses upon the roots of the vagus. The proof of this pressure is interestingly given in the fact that in early life the cornu is little connected with the nerve-roots, whereas in later life, and especially in cases showing chronic distension of the ventricles of the brain, the vagus becomes firmly united to the cornu of the fourth ventricle. So much is this the case that you will commonly find, when the brain is removed with only ordinary care from the skull, that the sides of the fourth ventricle are torn open, and the choroid plexuses protrude prominently from them. I have here a specimen of a brain removed in the ordinary way, in which the choroid plexuses are thus exposed. The very slight drag on the pneumogastric nerves which was caused by the cutting of the roots with a sharp knife has sufficed to pull open the lateral cornu of the fourth ventricle on each side.[1]

I would also here draw attention to the fact that the pneumogastric nerve, of all the cranial and spinal nerves, runs, perhaps, the shortest and straightest course from its origin to its escape from the dura mater. It forms, as it were, the central nerve of the whole system. Above it all the nerves incline upwards or forwards to their exit; below it all incline, more or less, downwards. But this nerve runs a straight, short, tense course, and as it is fixed at each end a little pressure must tell on it very directly. An observation of my late friend and colleague Mr. Hilton will serve to illustrate how tense is the root of the pneumogastric nerve, and, consequently, how subject to mechanical force applied to or about it. In Mr. Hilton's lectures on "Rest and Pain" he says, "But I suspect that if in such cases (concussion of the brain) the base of the brain be carefully examined the cause of death may be discovered in injury to the filaments of the pneumogastric nerve, near the origin from the medulla oblongata. Some years ago I clearly made out this lesion in a case of concussion which caused the patient's death. The only indication of local mischief which I could discover was the laceration of some of the filaments of the pneumogastric nerve." This observation of a most experienced and most skilful observer, seeing that no other part within the skull was hurt and the pneumogastric roots were torn, shows, in a conclusive way, how tensely they are stretched. And if they are tensely stretched, slight pressure upon them must be productive of not unimportant results.

Now, it cannot be a matter of chance that the roots of the vagus should be stretched so tightly across from the origin to the dura mater as to be specially picked out for laceration, and at the same time that the vagus alone, of all the cranial nerves, should receive a peculiar offset from the fourth ventricle. So that the ventricle puts out a finger-like process, or cornu, packed tightly full of a mass of bloodvessels to reach these stretched roots of the nerve, and to press upon them so hard that as life goes on the nerve and the finger-like process become firmly united together. Whatever may be the meaning of such an arrangement, it cannot be thought that it would exist without any signification or service, or function. No other nerve is thus treated, and the question therefore arises, What are the effects of pressure on this particular nerve? In answer to this question we may first observe that, if the vagus is stimulated by galvanism, the heart's beat is caused to stop thus:

FIG. 2.



Inhibition of frog's heart by stimulation of vagus.

Again, if the pneumogastric nerve is stimulated by digitalis, the result is to stop the heart in a similar way if the dose is large; but if the dose is moderate the heart's action is not stopped, but only made slower. And by graduating the dose of digitalis the heart may be made to go slowly in corresponding degree. But what will be the effect of pressure upon the vagus? An answer is furnished by an observation made by Czermak. This distinguished physician had a small osseous tumour in his neck, and he was able by pressing the vagus against this tumour to stop at will the beating of his heart.

---

[1] I may commend this very easy laceration of the cornu of the fourth ventricle by a slight drag on the pneumogastric to surgeons, for explanation of such cases of fatal concussion of the brain as appear at first sight to offer no anatomical lesion. The shock in fracture of the base is transmitted largely towards the eighth pair of nerves, and this pair is tensely stretched, so that if there is a severe jarring in the line of the posterior lacerated foramen, a sufficient vibration of the vagus nerve may be set up to tear open the fourth ventricle. Also, as to cases of unusually free and large discharge of watery fluid from the ear in frac-

We have, then, a mechanism plainly intended to do something, and we find the thing this mechanism is calculated to do is to check the action of the heart. Let us now see whether any beneficial result will follow from such checking of the action of the heart under the circumstances in which the mechanism is put in operation. It is clear that as the finger-like process is stuffed with tufts of bloodvessels the pressure it exerts will depend on the amount of blood in the vessels. The more blood the more pressure, so that it is when the vessels of the choroid plexus become distended with blood that the finger-like cornu which contains the bloodvessels will press upon the pneumogastric nerve and check the action of the heart, and thus prevent excessive inflow into the vessels of the brain. In fact, the contrivance will act exactly like the ball-tap which controls supply to a water cistern. Now, I am not saying that this is the only means of such check-action. Creatures unprovided with it show an automatic check upon the action of their vascular mechanism. But it is certain that the contrivance I thus describe will tend to control the entry of blood into the brain, and I think its development in the human brain bears a relation to the great size of the brain and to the extent of its blood supply, which requires a supplementary automatic check upon the entry of blood. Perhaps when this check is further developed in the advancement of the race the balance of activities between the mind and the heart may be still better regulated than is the case at present.

But I shall be asked for proof that when there is pressure of blood into the brain, the pulse is actually checked or slowed. Evidence is not far to fetch. Let us take a simple case—one which is constant in observed results. Take the variations in rate of pulse when we change our posture from horizontal to upright, and let me cite the well-known and careful experiments of Dr. Guy. This physician found by an extended series of observations that the rate of the pulse, when persons are standing, averages 81, but on these persons lying down, the rate of the pulse falls to an average of 67. The effect is just as if a moderate dose of digitalis had been taken. Lest it should be said that the increased rate of the pulse in the erect posture is due to the greater muscular exertion of standing, the persons under experiment were strapped to a board and supported in such a way that they did not use any exertion to keep themselves upright; and yet, when they were caused to pass from the horizontal to the erect position by a revolving movement of the board, the same increase of pulse-rate took place. Now, in the upright position the blood tends to drain easily away from the brain and reaches it with difficulty, so that the choroid plexuses would be less distended and the pneumogastrics less pressed upon. But in the horizontal position the blood goes to the brain more freely, the choroid plexuses are more distended, and the pneumogastrics more pressed upon, thus checking the action of the heart as if the person had taken digitalis. And, indeed, it will be found true that causes which involve too great a general pressure of blood into the brain slow the pulse. Thus, as we shall presently see, the effect of going into compressed air is to slow the pulse. Also the effect of a retention of great excess of blood into the skull in general inflammation of the brain is to slow the pulse. A slow, irregular pulse is, of course, one of the most significant of the group of symptoms which usher in meningitis. It is true that later in the course of this disease the pulse becomes quick again, and indeed quickens until it becomes impossible to count it. And it is true that when this quickening occurs the brain is still overfilled with blood, and these things being true, we have to explain why now the pneumogastric is no longer pressed upon and inhibited. The answer is quite clear. Under my care, as I now write, is a child in the clinical ward at Guy's; it has passed through the early stages of tubercular meningitis, and is in the last stage, with pulse 180 in the minute. I have given in the last two days large doses of tincture of digitalis to this child. Now digitalis has the power of calling out the action of the pneumogastric nerve, and so slowing the pulse. But in the case of this child, the digitalis does not show the slightest degree of such power—the child's pulse is quicker instead of slower. It is just as if a large dose of atropine had paralysed the pneumogastric, in which case it is known that digitalis will not slow the heart. We have here, then, evidence through the inefficacy of digitalis, that the pneumogastrics are paralysed, and hence pressure on their roots in the cranium naturally produces no result, any more than do the large doses of digitalis.

Such being the means of checking excessive entry of blood to the vessels of the brain, let us now take into consideration the automatic mechanisms which tend to check the exit of blood from the brain. The object is to oppose an automatic impediment to the exit of blood from the cranium which shall be efficient in proportion as the tendency of the blood to leave the cranium is exaggerated. First of all we may notice that there is a tendency to disfavour a ready exit of blood from the brain shown in the fact that whereas the arteries of the brain enter the base of it—that is, enter the part nearest to the heart, thus receiving their supply with all possible directness, and whereas the arteries of the brain then run upwards over the brain, the veins do not then descend in company with them, as veins generally do, but they run, for the most part, just the opposite way, ascending towards the top of the brain against the attraction of gravitation. The obvious result of such a disposition of the venous current is to delay the exit of blood, so that in case of feebleness of the current that very feebleness would tend to cause the blood to fail to go rapidly upwards against gravitation, to reach the sinuses, and escape from the skull. Now, Virchow also called attention to this retardation of motion of blood in the cerebral sinuses, especially by the dilatations of calibre and projecting partitions in the walls of the sinuses; and Dusch, with reason, further ascribes a retarding tendency to the peculiar form of the canals of this portion of the venous system, seeing that by deviating from the cylindrical form the proportion of the surface by which the blood meets the walls of the sinus to the bulk of the blood within the sinus is increased so that there is greater friction in proportion to volume.

But another and much more elaborate and efficient check to the exit of venous blood from the brain is seen in the curious opposition between the course of the current in the great veins at the back of the brain and the course of the current in the longitudinal sinus. Here we shall observe a self-acting mechanism which bears a most interestingly coördinated relation in its degree of efficiency to the degree of requirement which exists in each particular case. For when the human brain is compared with the brain in allied animal forms, it is seen that the superior intelligence which characterises Man is obtained through, or at least *with*, a backward extension of the hinder part of the brain, or, more properly, of the cerebrum; and in fact this backward growth does actually occur in the development of each human person, as may be seen in these diagrams of the brain in the later months of fœtal development. Now, observe the effect of this backward growth of the brain upon the course of its veins, and we see that as the brain goes back it carries with it the sources of the veins backwards away from the points of delivery of the blood into the longitudinal sinus which receives their contents. For it appears that the backward growth alike of the brain of the skull and of the dura mater takes place chiefly behind the points of junction of the hinder cerebral veins with the longitudinal sinus. The natural result of such an arrangement is to this effect. That just in proportion as the brain is developed backwards with the increase of intelligence and with the erect posture which intelligence seeks, just in such proportion is the blood from the newly developed part of the brain sent forwards into the sinus which receives it. But the blood in the sinus which thus receives a forward current is itself going backwards, and is in fact the blood coming from the front of the brain. Hence in the sinus there is an opposition of this current from the front of the brain to the current from the back of the brain, which meet and check each other and so diminish the freedom of exit of blood alike from the front and back of the brain, and detaining and making less free the rush of blood in the anterior part of the brain, which the erect biped shares with lower animals, and perhaps keeping the animal

---

tures of the base, it may be noticed that the damage done to the skull is apt to run through the temporal and occipital bones where they meet; and in the violent laceration and crushing action of the crash the pneumogastric nerve is liable to get a sharper pull than is given it in cutting it with a knife. If, then, at the same time, a fissure is made through the dura mater and bones, reaching the tympanum and tearing its membranes—and I have traced such a fissure in more than one case, —a direct road is thus opened for the flow of liquid from the fourth ventricle through the external ear.

down in him to some degree; at the same time staying the blood in the whole increased mass of brain so as to render any movements in the blood less sudden. In this way the greater size of brain that induces the erect posture and goes with a disposition to take up a great variety of postures with more or less brain activity, this greatly increased brain, is kept accommodated with blood by reduction of tendency to outflow of its venous current. In short, the brain is compelled to economise its supply. Such a meeting of the backward current by a forward current must have the same effect as occurs when at the mouths of rivers the current of the river is met by the rising of the sea, so that a rise of water in the river is a consequence as in the production of tides. Nay, the obstruction being by means of one current actively opposing another is so direct that it may almost be compared to a lock in the course of a stream. The result as to the outflow from the longitudinal sinus will be that, instead of a current from the veins of the brain running with a certain velocity through and out of the sinus, the forward and backward currents neutralise each other in the sinus and the blood goes out from it, only as an overflow under the pressure existing in the veins at the time; no overflow if no pressure. And if we trace the effect backwards upon the state of the veins we see that it must tend to keep the veins full under all circumstances, locking the current in when it is feeble, and so preventing too ready an escape of blood in sudden change of posture, &c. On the other hand, when the current of blood through the brain is strong, the antagonism of the blood-streams would cause them to oppose and lock each other, perhaps too thoroughly, so that a scheme of relief is necessary as a sort of weir or escapement to allow excess of blood to pass by the lock which there is in the longitudinal sinus. This weir is provided by sending the blood from the whole of the lower parts of the brain, by means of the inferior longitudinal and straight sinuses, to a point beyond the lock which I have described; so that there is thus a free exit for some of the blood when the pressure is great.

Now, if we consider the parts of the brain that discharge their blood beyond the lock in the longitudinal sinus we see that they include the parts more essential to animal life, especially the great ganglia at the base of the brain in the medulla oblongata, pons Varolii, thalami, and parts of the corpus striatum. Blood is sent to these essential parts of the brain immediately the arteries enter the skull, so that they get their supply at high pressure, and the blood comes away from these parts of the brain by veins that join the sinuses of exit at points beyond the lock, and near the ending of the sinuses in the jugular veins; nay, some part goes independently through the inferior petrosal sinus directly out of the skull. Thus a free circulation takes place in the vital parts of the brain, whilst those parts which subserve only the relative unessential process of thinking have their blood-current partially locked, and are oblige to economise it, the free circulation of the blood in the vital parts of the brain relieving the lock when the pressure is great.

Amongst the parts that receive their arterial supply immediately the great vessels enter the skull are the choroid plexuses both of the lateral and fourth ventricles, and I have already shown how the overfilling of a particular part of the plexuses in the fourth ventricle acts like a ball-tap in putting a direct check upon the entrance of blood into the arteries of the brain. But a very considerable easement of the stress of blood is provided by the great capacity of the choroid plexuses themselves. These plexuses will contain much blood, and when the entry of blood into the brain is free they fill rapidly with it, and as they lie in the ventricles of the brain, and are bathed by the cerebro-spinal fluid, they press upon and expel this fluid into the spinal canal, where it finds accommodation by pressing in its turn on the spinal vessels. The veins from these plexuses form part of the escapement system.

And this locking system which I have described does not act without telling slowly on the arteries which feed it; for these arteries being relatively unable to empty themselves, as other arteries can and do, have to suffer greater strain; and so in time the arteries which feed the locked circulation in the seats of will and thought become injured, and the sum of injuries accumulates upon them; whereas the more unimpeded vessels of the base of the brain, which feed the parts essential to life, whose veins form the weir, are not so much strained or so much injured, because they are unobstructed. Hence, when at length some overstrained vessel must burst or be blocked, the vessel which so suffers is in nine cases out of ten a branch of an artery which sends blood to the locked longitudinal sinus, not a vessel which sends blood favoured by gravity to the more open lower sinuses.

Again, I think it reasonable to reflect further that wearing out of the cerebral arteries would affect first the arteries of parts whose activity is a matter of education, and therefore of will and intelligence, because the activities which are organised through education are, as it were, grafted on the more stable activities that are natural to animal life. And the exaggeration of action which education compels cannot be supposed to be prepared beforehand by the animal development in the same way as the animal development prepares beforehand a provision for the functions of purely animal life, so that educated activities act through and with a relatively less well-prepared vascular system than the more natural activities are favoured with. And hence, when a general difficulty overtakes the whole circulation of the brain, the least stably-organised and overstrained vessels of the parts whose function is exaggerated by education would give way first. In this manner we may explain why it is that either the distal portion of the upper extremity, the chief subject of education, or else the organisation for speech, one or the other of these is the first injured in trivial, and the last to recover in severe arterial breakdown. I think it is from this cause that the strain on the locked system of cerebral arteries picks out for its earliest victims the most highly educated parts. So that an attack of hemiplegia nearly always lets off most lightly the limbs and parts of limbs which subserve the animal procedure of walking and the swing of the shoulder and elbow, and so forth, and fastens itself on parts whose education has spun out and elaborated, and relatively weakened the vascular supply of their department of the nervous centres. These flourishing but not purely natural departments fail just as you may see often upon grafted rose-bushes that a more vigorously growing graft, which has flourished grandly whilst the stock was sound, will be first to wither when the stock begins to fail; whereas natural shoots, which before were more moderate in their luxuriance, will commonly survive.

Gulstonian Lectures
ON
ANÆMIA.

Delivered before the Royal College of Physicians,

BY SIDNEY COUPLAND, M.D., F.R.C.P.,

PHYSICIAN TO THE MIDDLESEX HOSPITAL.

LECTURE I.—PART II.

Etiology of Anæmia: Loss of Balance between Blood Formation and Blood Destruction; Deficiency in Income or Excess in Expenditure, or both combined. (a) *Defects of Blood Formation:—Quantity and Quality of Food—Oxygen—Derangement of Digestion, Assimilation, Sanguification.* (b) *Excess of Blood Destruction:—Prolonged Muscular or Nervous Activity—Excessive Secretion—Catarrh—Inflammatory Effusions—Suppuration—Hæmorrhage—Albuminuria—Malignant Growths—The Cancerous Cachexia—Tubercle—Fever—Special Blood Changes, as in Scurvy, Rheumatism, Syphilis, Malaria.—Mineral Poisons: as Lead, Mercury, Phosphorus (?)—Parasites. Influence of Age, Sex, Heredity, Occupation, Light, Air, and Temperature—Climatic Conditions.*

HAVING thus considered the chief points regarding the composition of the blood and its variations in anæmia, I pass now to inquire in what way and under what influences the anæmic condition is induced. This inquiry involves the whole subject of the nutrition and expenditure of the body, together with other factors which, inherent in the individual or operating from without, tend to place the organism in a state unfavourable to the complete performance of the functions of the blood. All the complicated processes of the living animal organism are comprised in a series of changes in composition of the elements of the body, and especially of the blood, for it is through it that the normal balance between decomposition and reconstruction takes place. The cycle of changes must be complete, the amount of nutriment conveyed by the blood must be sufficient to replace the waste occasioned by tissue-change, and this latter must not be out of proportion to the amount of nutriment if the balance is to be maintained. If there be defects in the supply, the blood and tissues suffer inanition; if excess in expenditure, they suffer undue consumption. In other words, in so far as its vital processes are concerned, the body may be regarded as a complex machine requiring a definite supply of oxidisable material and of oxygen for the performance of its functions—functions which may be expressed in terms of mechanical force and its correlative, heat. We have, therefore, to consider the means whereby such material is supplied, and its supply maintained and regulated, to deal with the manner in which the body takes in this material, and how it disposes of it. If the material itself be deficient in quantity or quality, or if the methods by which it is prepared for disposal be defective, the mechanism of the body will, *pro tanto*, be deranged. The blood will be poorer in the material to be disposed of. On the other hand, if the mechanism for the conversion of the material into force be faulty, so that an excessive amount is used up in the work of the body, the blood again will be impoverished. In seeking, then, for the known causes of anæmia, we may expect to find them in these two directions —deficiency of income and excess of expenditure. I will speak shortly of each of these in turn.

In dealing with the subject of food in relation to the blood and tissue changes, attention may be mainly directed to the nitrogenous ingesta, which serve the purpose of building up the tissues, whilst the waste of tissue is measured by the amount of nitrogen excreted in the form of urea. The other organic constituents of a mixed diet—fats, carbohydrates, and gelatine,—do not directly influence tissue metamorphosis; but are none the less important in maintaining the body in a state of health, supplying by their direct oxidation heat and force, which otherwise would have to be furnished by the conversion of proteids. A sufficiency of water and of salts is also necessary to enable the processes of nutrition to go on normally, and indirectly their diminished supply induces blood changes allied to those of hypalbuminosis. The whole blood is reinforced by taking food; both red and white corpuscles are increased, and the capacity of the blood for oxygen thereby augmented. There are differences of opinion as to the precise manner in which the proteid constituents of food are disposed of, but this much is clear: that part is directly converted into fats and urea, the former to be further oxidised and eliminated as carbonic acid, or stored up in the form of adipose tissue; part retained by the liver to subserve its glycogenic function; part devoted to tissue metabolism; and perhaps a further portion to remain in storage in the blood, to be utilised in case of need. This last-named destination of the proteids is disputed by Dr. Michael Foster (to whose work I am largely indebted for this portion of the subject) on the ground that metabolism does not take place in the blood itself, but only in the tissues; and that the comparative excess of consumption of proteids in the early days of inanition, as shown by Voit and others, only proves that there is a store of material above the immediate wants of the body, not that the place of this storage is the blood. It is found also that nitrogenous food directly provokes tissue change up to a certain point, the limit being in great measure determined by the amount of oxygen available, so that the increased metabolism must be in relation to the increase of hæmoglobin in the blood and of its capacity for oxygen. Therefore, also, oxygen is as essential as food; and when from defective blood formation the amount of oxygen in the blood is diminished, tissue change is arrested, and certain retrograde metamorphoses take place which form the leading effects of the anæmic state. Quinquad found in certain cases of inanition a reduction in the hæmoglobin to one-sixth of the normal, and proved also the rapidity with which this constituent is reinforced when food is taken by starving persons; and Voit's experiments established the fact that in starvation the blood wasted in direct proportion to the loss of body weight. This obvious cause of anæmia finds abundant illustrations in disease. There is no anæmia so profound as that which accompanies grave organic disease of the stomach. Indeed, Dr. Fenwick is of opinion that the fatal forms of progressive anæmia, to which hitherto no satisfactory cause has been given, are due to atrophy of the gastric glands; that such an atrophy—if it be primary—would suffice to produce this grave anæmia is possible, but it should also, one would think, be more often accompanied by general wasting of the body—a wasting which is not by any means a constant feature of "idiopathic" anæmia. When there is wasting, latent gastric disease may be suspected. A few weeks ago there was admitted under my care at the Middlesex Hospital a man sixty-three years old who had been attacked with hemiplegia the day before. For six months past he had suffered from dyspeptic symptoms, and had grown very pale. The pallor had rather rapidly increased of late, and on his admission it was most extreme; but there was no history of any hæmorrhage, and only equivocal evidence of its occurrence in the blackening of the fæces. He was, further, much emaciated, but careful examination failed to detect any abnormal condition of the abdominal organs. One could only suspect some latent gastric disease—cancer or ulceration, with unnoticed hæmorrhages—and attribute the recent increase in the pallor to the supervention of a cerebral hæmorrhage. The number of corpuscles was 25 per cent. of the normal. For upwards of two weeks he lay in an impassive, corpse-like state; and on his death we found a chronic ulcer of the pylorus, with general chronic gastritis. The hemiplegia was due to blocking of the left internal carotid and middle cerebral artery, the former vessel being much narrowed by atheroma at its origin. Such cases as this must be eliminated before diagnosing idiopathic anæmia. Any interference to the reception or proper digestion of food, as imperfect mastication, hindrances to deglutition, functional dyspepsia, and also irregularities in taking food, as well as deficiencies in its quantity or quality, rank among causes of anæmia needing no further illustration. And as oxygen is as necessary as the ordinary elements of food for tissue metamorphosis, any interference with its due supply favours anæmia, as proved in the persons of those who habitually dwell under conditions of bad ventilation, or impurity of the atmosphere—conditions so universal and prevalent that they may fitly be included under predisposing influences. They explain the anæmiating influence of life in a crowded city, with its smoke-laden atmosphere, as contrasted with the conditions obtaining in the purer country air. Derangements in digestion, especially those of simple functional dyspepsia, are maintained by the anæmic state they induce, and it is often difficult to find where the vicious circle commenced; hence the liability to mistake effects for causes, which is one of the chief problems connected with this subject.

Of the glands which aid the peptic in the labour of digestion, the liver and pancreas may severally, when deranged, be the cause of profound inanition and anæmia. The liver has so many other important functions, and is probably so directly concerned in the process of blood destruction (and possibly of its formation also), that the manner of its action in producing anæmia is more complex than that of the pancreas, which is more purely concerned in the digestive process. Of diseases of the pancreas, however, there is only one with which we associate definite symptoms, including a marked anæmia, and that is cancer; when we have introduced a new element, the abnormal cell-growth, aiding in the impoverishment of the blood. But the marked wasting and bloodlessness accompanying such disease are surely out of proportion to the development of the cancerous mass, and are readily accounted for when the large share taken by the secretion of the gland in the digestion of proteids is borne in mind.

Passing to the processes of assimilation and absorption, it would appear from physiological data that the lacteals are little concerned in the removal of products of proteid digestion, being mainly devoted to the absorption of fatty matters. This, however, is hardly consistent with the extreme degree of inanition associated with chronic mesenteric disease, which points to a lacteal as well as a portal absorption of nitrogenous matters. We are thus led up to the final stage of blood formation; for derangements of the whole lymphatic system, and of the allied blood-forming glands, play a very notable part in the etiology of anæmia from inanition. For in the work of nutrition the share taken by the lymph is not less important than that of the blood itself. Of the two fluids, the lymph, which has its analogues in the whole animal kingdom, would almost seem to be the more necessary. But the lymph contains no hæmoglobin. This special substance—found in all vertebrates—is that which gives the blood its distinctive character, and enables it to perform its respiratory function in the widest sense. The lymphatic system is not a mere appanage to the blood system; it is an essential complement to the latter, and reinforces it in blood-corpuscles.

As I have previously pointed out, the process of blood formation, in so far as its distinctive cellular elements are concerned, appears to take place in several organs and regions of the body, where blood and lymph systems blend, and we look naturally to disorders in their mechanism to explain imperfections in the composition of the blood, not accounted for on more obvious grounds. Such derangement might result in the imperfect formation of corpuscular elements, in an over-abundant supply of leucocytes, or a relative increase in these, and of immature corpuscles failing to be transformed into the red globules. Such conditions do occur, and until we are in a position to give a name to the morbid change in the cytogenic organs themselves, we are bound to use provisionally such terms as leukhæmia and anæmia to denote the diseases of which the blood state is only a secondary result. We may be able to differentiate a leukhæmia due to splenic, lymphatic, or medullary disorder respectively, and the same may be possible as regards anæmia; and there is nothing incongruous in the idea, for example, that in Hodgkin's disease there may be sometimes a condition of lymphatic anæmia, and sometimes a condition of lymphatic leukhæmia, the question as to the distinction between such forms being one of the relative degree to which red corpuscles and leucocytes are respectively increased or diminished in number. It is from the analogy afforded by the existence of such diseases that we are driven to conclude that cases where anæmia is throughout the leading and only symptom, depending on no derangement of normal nutrition, either in the way of income or expenditure, are due to changes in these blood-forming viscera. At present but little progress has been made in this direction, and as I hope to show the derangement at the root of idiopathic anæmia is hardly more known to us than it was to Addison, who in his search for some organic change in these organs in such cases discovered the supra-renal disease, and brought to light a new clinical entity, whereby his name has become famous.

Having thus slightly, and, I fear, imperfectly pointed out how the blood may be impoverished from defects either in the materials of its formation or in the manner in which these materials are converted into blood, I pass to the remaining and far more extensive causes of impoverishment, where there is undue expenditure of tissue and of blood.

The whole work of the body is effected by oxidation, not in a simple manner by the direct combustion of material contained in the blood, but of that which is stored up in the tissues to which it has been brought by the blood. Setting aside the conversion of carbon compounds and considering only the subject of nitrogenous metabolism, we find that the nitrogenous matters brought by the blood are utilised to repair tissue waste and to aid in the actual production of energy—i.e., mechanical motion and heat. Every molecular change is accompanied by heat production, and mechanical motion appears under different forms in many of the vital acts. Muscular action is the chief source of this expenditure. It is marked by rise in temperature, the separation of carbonic and lactic acids out of proportion to the amount of oxygen consumed, indicating that some highly complex molecule is destroyed, the nitrogenous portion of which is retained by the muscle. Such changes go on, but to a lessened extent, in the muscle during rest. The nutrition of muscle, then, consists in a constant formation of contractile material periodically greatly decomposed, and as this decomposition is accompanied by heat much force is expended. Over-work of muscle does not impoverish the blood so much as might *primâ facie* be expected, and this for several reasons. The circulation is accelerated by muscular activity, and tissue changes go on more rapidly so long as a sufficient amount of oxygen and carbon compounds is supplied to the working muscle; and hypertrophy of a muscle called forth by extra work enables it to utilise more material. This, however, implies an increase in the intake of the blood; and were it not that a limit was placed by the condition of fatigue the blood would be greatly impoverished. As it is, long-continued exhausting physical labour, and its frequent repetition, undoubtedly cause anæmia. I might remark in passing that if any good is to be derived from the extravagant feats of physical endurance at present so popular, it should be by utilising them for physiological inquiry in these directions.

The opposite condition—that of lack of normal muscular activity—is a more prolific cause of blood-impoverishment than excessive action; but its mode of operation is, of course, very different. There is then diminished tissue change, diminished oxidation, and the blood suffers from being imperfectly renewed, and not from being drawn on for extra supply. Conversely, inability for physical exertion, and the readiness with which this is followed by fatigue, are prominent features of the anæmic state, and are readily explained by the lessened power of oxidation.

As regards expenditure in the production of nervous energy there is less certain knowledge than is the case with muscle. The actual chemical changes taking place in a nerve during the passage of a nervous impulse are comparatively insignificant, but those which occur in the central mechanism are probably much greater. The complexity of the construction of a cerebral molecule, for example, is very great, and its activity must, no doubt, depend upon a due supply of oxygen, as in the case of other tissues; and it is probable that for every act initiated by the nerve-cells the energy must be supplied by oxidation changes in these complex molecules. More than this, however, is probably concerned in the question of the influence of the nervous system. Its intimate relations with all parts of the body point to an exercise of control over blood formation as over nutrition and secretion, so that under certain conditions the nervous system may bring about an anæmia other than by the exhaustion of material supplied it by the blood. It is only on such an assumption that the occurrence of a profound, lasting, and even progressive anæmia following great mental shock or emotional disturbance can be explained. I am not prepared to say that this same influence does not operate in the production of anæmia from exhausting mental labour, from anxiety, or from want of sleep. It may be one factor, the other being the disproportionate expenditure of material.

In the act of secretion there is more obvious reason for believing that excessive function entails a loss of material from the blood. The secreting cell not only takes up material and converts it into its peculiar product, but such conversion often demands the destruction of the cell itself. Some secretions are composed of more complex substances than others; and the drain on the blood must be proportionally greater when these glands are too freely exercised. One of the best known instances of a symptomatic anæmia is afforded by such excessive and prolonged activity of the mammary gland, which yields a product rich in all the main elements of the blood. A like instance is afforded by the product of the male generative organs—a product of a peculiarly stable character, and endowed with highly specialised properties. It is plain on mere *à priori* grounds that an excessive production of this secretion must cause undue drain on the blood, and such is a well-recognised fact, although in both these instances the effect on the nervous system as the controller of blood formation must not be entirely lost sight of. Probably it is the same with every other secreting gland, in extent varying with the quality of the secretion. The transition from conditions of excessive discharge of normal products to those of perverted and abnormal discharges is slight. We may comprehend in one view all the abnormal fluxes—from a simple mucous catarrh to an abundant purulent discharge from a mucous tract, where the formed elements of the blood compose a great part of the discharged material. Such outpourings not only impoverish the blood directly, but where, as in the case of the intestine, they involve organs subservient to digestion and assimilation, they of course interfere with the formation of blood; and the rapidity with which a diarrhœa produces anæmia is well known. Such causes of blood impoverishment may lead to other conditions, where either the blood itself or its albuminoid constituents are poured out from the vessels. Of hæmorrhage nothing need be said. Even the monthly loss by the catamenia is represented by an actual fall in the richness of the blood. Inflammatory effusions into serous sacs, when abundant, must necessarily entail anæmia; but I do not know if the degree to which this occurs has been much studied. Quinquad, in three cases of acute pleural effusion, found a marked reduction of hæmoglobin and of the solids of the serum, and also noticed that paracentesis was followed by a further reduction of these constituents. Large inflammatory exudations, such as occur in acute pneumonia, are also accompanied by a fall in these constituents, but, according to this writer (and in that respect the observations of Drs. Baxter and Willcocks coincide), not to a very marked extent, especially when the high degree of pyrexia is taken into account. Passing from simple inflammatory exudations to suppuration, we meet with conditions of drain on the blood too obvious to require illustration.

The anæmia of chronic albuminuria forms another example in this lengthy category. A notable deficiency in red corpuscles has been shown to occur in chronic Bright's disease, and the supervention of dropsy is apparently due to the replacement of albumen by water in the blood.

The relation of malignant growths to the composition of the blood involves a subject complicated by the question of cachexia. Undoubtedly, when malignant disease is of rapid development it must deprive the blood of much nutriment, perverting it to its own ends, and living on the body in a truly parasitic manner. Or if the disease involve organs essential to digestive or nutritive functions, it must obviously indirectly interfere with blood formation. It is said that in cancer the red corpuscles are not only diminished in number, but are smaller in size than the normal, and that the hæmoglobin in cancerous subjects becomes reduced to a very remarkable degree. But that this precedes the development of the disease there is no warrant for saying, or that there is in cancer a cachexia apart from the circumstances of the growth itself, and the additional drain frequently occurring from the ulceration and hæmorrhage of the diseased mass. I have seen cancer arise in the robust and plethoric, and in such subjects it grows with terrible vigour; but it is not, of course, always so, and the problem is to discriminate between an underlying blood-condition and that induced by the malignant growth itself. It seems to be otherwise with regard to tubercle; and among the numerous points in which medicine is indebted to Trousseau is that where he declared the fact of the existence even of marked anæmia in subjects of tubercular tendency before the local manifestations of the diathesis appear. Whether it be that in these individuals the lymphatic system is primarily deranged, and the work of sanguification impaired, or whether we may look upon tubercle as a true blood-disease, I do not know. When, however, tuberculisation is declared other factors come into play to aid in the production of the anæmic state; there is abundant cell-formation and destruction of tissue, whilst prominent among all the influences is *fever*. On its special influence in inducing anæmia I must now say a few words.

The central fact in the febrile process, next to the heightened body temperature, is the increased metamorphosis of the albumen of the body, as shown in the rapid wasting of the tissues and increased elimination of urea. When to this is added the impairment of the digestive and assimilative functions, we get in fever a combination of both the conditions of blood impoverishment. The blood suffers as well as the other tissues; its corpuscles appear to be more rapidly disintegrated, their number is notably diminished, the hæmoglobin is reduced, and the pigment excreted in excess. Consequently, to maintain the increased oxidation the circulation is accelerated and the respiratory changes are more rapid. Wagner says,[1] "without any doubt metamorphosis is increased in fever. This does not occur as a simple and uniform increase of the normal process of metamorphosis, but the process of oxidation of nitrogenous substances is made more active than that of the non-nitrogenous. More especially there occurs a greater destruction of albumen, chiefly indicated by increased excretion of urea, and that in spite of the fact that the conditions for its separation are less favourable in fever because of the diminution in the amount of urine. Even under the most favourable circumstances we find in fever patients an average increase in the excretion of urea amounting to more than double what is thrown out in non-febrile states under otherwise similar conditions. According to a number of investigations, it is the red blood-corpuscles—that is to say, those elements which we know to take up oxygen from the air and serve to transport it to the tissues—which suffer most in fever. If the organism in fever cannot appropriate as much oxygen as in the same dietetic conditions in the non-febrile state, it likewise cannot furnish as much products of oxidation. But as larger quantities of oxygen are used in the formation of a greater amount of urea, it is probable that an excessive formation of other products of combustion (so often asserted) does not take place." The present methods of blood analysis have not wholly substantiated these inferences (Baxter and Willcocks), but as these methods take no cognisance of alterations in the density of the blood, these results can hardly be quoted against the manifest effects which fever produces in its subjects, and the plain evidence of increased tissue metamorphosis afforded by urinary analysis.

I must also enumerate, to complete the list of known causes of anæmia, certain diseases (in many of which fever plays a part) which are specially characterised by alterations in the composition of the blood. Scurvy is an example of such a disease. Arising in defects of diet, it is, as Dr. Ralfe has demonstrated, productive of a diminished alkalinity of the blood, which in its turn leads to corpuscular disintegration, and all the effects following upon this. These effects are probably then largely dependent on the anæmia of the disease, for the changes in the viscera and bloodvessels are similar to those met with in profound anæmia. Quinquad has noted a very marked reduction of hæmoglobin in scurvy. In acute rheumatism anæmia is a prominent symptom from the first, and it is an example of a disease in which the blood is directly influenced. Diminution in corpuscles has been noted both in acute rheumatism and in acute gout. The anæmia induced by the malarial poison is sufficiently accounted for by the degree to which the more important organs concerned in blood formation are influenced by it. The subject has been especially studied by Kelsch, who found in simple intermittent fever a considerable decrease in the number of red corpuscles after each febrile paroxysm, followed by a partial return to the normal—a renovation which was not accomplished owing to the recurrence of the paroxysm, so that the anæmia is maintained and intensified as long as the fever lasts. The subsequent malarial cachexia is marked by a lowering in the number of blood-corpuscles. Quinquad's estimations of hæmoglobin teach the same fact, and, in addition, he remarks upon the considerable diminution in the solid matters of the serum in malarial disease. Lastly, in syphilis we have an animal poison, probably directly affecting the blood, and showing its effect in diminution of the red corpuscles and hæmoglobin.

Amongst mineral poisons lead and mercury are powerful agents in the impoverishment of the blood. Workers in lead are always anæmic, often to an extreme degree. This may be in part due to the direct action of the metal on the blood; but it is at least an open question whether, in view of its action upon the nerve tissues, it does not also operate by impairment of sanguification through disordered innervation. Observations are not wanting to show that there is a considerable diminution in corpuscles and colouring matter in chronic lead poisoning. I have included phosphorus in this category, although its precise mode of action is doubtful; acute poisoning by phosphorus leads to changes which seem related to deprivation of the blood of its oxygen; but whether this is in consequence of a directly noxious effect on the corpuscles or not I cannot say.

Lastly, some forms of anæmia in tropical climates, especially that form known as "Egyptian chlorosis," were explained by the discovery of a blood-making nematoid parasite, the *anchylostomum duodenale*, which may exist in large numbers in the upper part of the alimentary canal, where it is conveyed by the ingestion of impure water. The obscure disease which proved fatal to some of the workers in the St. Gothard tunnel was shown to be due to the presence of this parasite, which "bites its way into the mucous membrane, pierces the submucous cellular tissue, and subsists on the blood. After its removal there remains an ecchymosis, the size of a lentil, the centre of which presents a white spot of the size of a pin's head, with a fine hole. Out of these wounds the blood oozes into the intestinal cavity" (Wagner).

Having thus reviewed the conditions liable to lead to the impoverished state of blood known as anæmia—conditions of defective nutrition and impaired sanguification on the one hand, excessive expenditure and loss of nutritive elements on the other, and certain specific and other poisons, and parasites, there yet remain for consideration certain influences in the individual or in his conditions of life which operate powerfully to the same end. These influences—to which, for want of a better term, the word predisposing is usually given—include the factors of age, sex, heredity, and occupation; and the influence of light, air, and climate. With a brief reference to each of these in turn I shall conclude this portion of my subject.

In the growing organism the process of blood formation is at its height. We have seen how in fœtal life the elements of the blood are developed from the mesoblastic tissues almost indiscriminately. As parts become more specialised this function is limited to cetain special tissues, which are embraced under the term "cytogenic." In infancy and childhood the cytogenic tissues obtain their acme of development, and share with all the nutritive processes in the work of building up the body. The whole organism is thereby modified; it is mobile and plastic; repair and renovation are more rapidly effected; tissue change, and therefore oxidation, are increased, the temperature of the body heightened, and circulation and respiration accelerated. I cannot forbear quoting the terse sentences of Dr. Michael Foster as he sums up the nutritive conditions obtaining in the infant organism. He says:[2] "Metabolism is directed to constructive ends. The food taken represents, undoubtedly, so much potential energy; but before that energy can assume a vital mode the food must be converted into tissue; and in such a conversion, morphological and molecular, a large amount of energy must be expended. The metabolic activities of the infant are more pronounced than those of the adult; for the sake, not so much of energies which are spent on the world without, as of energies which are for a while buried in the increasing mass of flesh. Thus the infant requires, over and above the wants of the man, not only an income corresponding to the energy of the flesh actually laid on, but also an income corresponding to the energy used up in making that living sculptured flesh out of the dead amorphous proteids, fats, carbohydrates, and salts, which serve as food." Thus, then, in the growing organism we have not only a greater instability in the nutritive processes, but also a direct source of expenditure in the very fact of growth itself. In consequence of that instability, we find how comparatively slight causative influences may lead to considerable defects in the blood, reducing it below the physiological standard; and in the fact of growth we see how the tissues may demand more nutriment than the blood can supply, and an anæmia special to the period of childhood and adolescence may readily be provoked.

---

[1] Elements of General Pathology (Seguin's Edition), p. 660.

At the other extremity of the cycle of life, when the demands are lessened, when all tissues and organs more slowly perform their functions towards the close of the long years of activity through which they have passed, when all the nutritive processes take place with a sluggishness in contrast to the period of active growth; the blood (no longer required for the purposes of growth or the renewal of tissues) loses in corpuscular richness and in hæmoglobin, so that one feature of the natural decline of life is the presence of slowly deepening anæmia, which in its turn probably aids in the diminution of the vital powers. It is plain that a very slight derangement, either in the direction of intake or that of undue waste, must readily influence and intensify this senile anæmia and marasmus.

Turning now to the contrast afforded by the sexes, which up to the age of puberty advance almost in parallel lines, we find, in the first place, there is a difference in the precise composition of the blood (see Table I.), that of the female being notably less rich in corpuscles and hæmoglobin than that of the male; and although this difference in health is, doubtless, in precise relation to the amount of work called for in each sex, yet, in consequence of it, the female is rendered more liable to anæmia. She is also subjected to influences special to her sexual function. Ovulation and menstruation go on in health with regularity, and the blood loss they entail is readily renovated. But they are most easily influenced by derangements in health and nutrition; and, on the other hand, when diminished or excessive, may be important factors in the production of anæmia. Pregnancy, the puerperal period, and lactation severally subject the female to anæmiating conditions, and the cessation of the menstrual function is often the period at which anæmia is developed.

I have no doubt that heredity plays some part in disposing the organism to anæmia, but it is not easy to give instances. A tendency to anæmia may certainly be transmitted, just as a tendency to hæmorrhage, in hæmophilia.

The other conditions, which I have included under predisposing causes, frequently co-operate. Occupation may involve deprivation of a due amount of light and air, the exposure to heightened temperature, and a want of due amount of sleep. I need hardly particularise them further: they are influences which are almost as much exciting as predisposing causes of anæmia; they stand, at any rate, on the borderland between the two groups in the etiology of the condition.

The influence of climate is well known as favouring the anæmic state, the subjection to prolonged tropical heat having a direct influence over and above that which is due to the inertia called forth by life under such conditions.

In conclusion, it must be borne in mind that any given anæmia may arise from a multiplicity of causes, each of which is sufficient of itself to have induced the state; and in the second place the impoverished blood itself reacts on the organism in such a way as to maintain and intensify the anæmic condition. For all the vital processes are influenced by blood defective in the oxygen-carrying substance—hæmoglobin. Hence the capacity of blood for hæmoglobin must be increased, as well as the removal of the primary cause or causes, if any given anæmia is to be remedied. Metabolism must be quickened, and oxygen supplied for that purpose. I should have hesitated, in this hasty survey of the known causes of anæmia, to take you over ground so familiar if this were all that the subject comprised; were that the case, there would have been no need to discuss the subject at all. But when the category of known causes is exhausted, there remain cases of more or less profound and progressive anæmia, to which hitherto no sufficient explanation has been given. It is the existence of such a class of "idiopathic" cases that has induced me to speak to-day of the factors known to operate in producing the anæmic state, before proceeding to the consideration of that class of diseases to which I shall invite your attention in my next lecture.

CASE OF

ANEURISM, FIRST OF ONE FEMORAL ARTERY, THEN OF THE OTHER;

LIGATURE OF BOTH WITH CARBOLISED CATGUT, AND ANTISEPTIC TREATMENT; CURE.

BY RICKMAN J. GODLEE, M.S., F.R.C.S.,
ASSISTANT-SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

AT the present time, when we have been hearing so much of cases in which the application of the catgut ligature to an artery in its continuity has been followed by unsatisfactory consequences, it may be well to place the following on record, which, besides its bearing upon this particular question, is one of very considerable clinical interest. I may preface the account of the case by saying that not only was the progress of the patient after both operations quite satisfactory, but there can be no doubt that both of the arteries to which the ligatures were applied have been completely obliterated at the seat of operation.

A. T——, aged thirty-four, was admitted under my care into University College Hospital on Aug. 27th, 1878. By occupation he was a cab-driver, and had been a great beer-drinker, but had not taken much spirits. He had suffered from gout, but there was no history of rheumatic fever, nor could conclusive evidence of venereal disease of any kind be obtained: he was unconscious of having sustained any injury. For a fortnight previously the patient had noticed a slight catch in the knee and some pulsation, and for nearly a week he had suffered some actual pain. His general condition was not good: he had a bloated appearance, with distended cutaneous veins, a furred tongue, and a tendency to fine tremors of the limbs. He was emphysematous, and had scars of old ulcers on the legs. The apex beat was hardly to be felt, except at the epigastrium; but there was no cardiac murmur, and but slight tendency to arterial disease, as shown in the more superficial arteries of moderate size. In the right popliteal space was an aneurism of considerable size and irregular in shape. The pulsation, which was comparatively superficial, and seemed to indicate that the walls of the aneurism were thin, was most marked two inches above the lower border of the internal condyle, but it extended outwards to the outer border of the limb, and upwards to a line three inches above the crease of the ham. The knee was slightly flexed, and the limb, which lay upon its outer side, was considerably œdematous below this joint, the cutaneous veins being markedly full. The posterior tibial pulse was weaker than that on the opposite side.

At 8.30 P.M. on Aug. 27th the limb was bandaged, and after being flexed at an acute angle, was fixed by means of bandages in this position, some cotton-wool having previously been placed in the ham. Half a drachm of bromide of potassium and half a drachm of tincture of opium were administered. There was considerable pain during the night, and the patient slept very little. The following morning the bandages were loosened, but as no change had occurred in the aneurism, they were reapplied till 4 P.M. on the 28th, making altogether nineteen hours and a half, when beyond the disappearance of the œdema from below the knee no alteration had taken place. On the afternoon of the 29th I had proposed to ligature the superficial femoral, but when taken into the theatre the patient's condition appeared so critical, his pulse becoming very feeble and his countenance cyanotic, while the tremor previously noted had markedly increased, that it was decided to defer the operation for a time. He was accordingly taken back to bed. A low diet was ordered, and a mixture containing ten grains of iodide of potassium and twenty grains of bromide of potassium was given every three hours. On Sept. 2nd compression was begun with Carte's compressor, and continued for four hours and a half without effect. The patient complained of great pain, so that the treatment could not be continued for a longer time. On Sept. 4th digital compression of the common femoral was practised for twelve hours, the pulsation in the aneurism being completely arrested for by far the greatest part of this time. This again caused the patient almost unbearable pain, though hypodermic injections of morphia were freely administered. On Sept 6th, as the patient's general condition had decidedly improved, and as the means adopted for the cure of the aneurism had proved completely ineffectual, I proceeded to tie the superficial femoral artery in the usual way at the apex of Scarpa's triangle. A catgut ligature kindly given me by Mr. Lister was employed, and strict antiseptic precautions were followed throughout the operation. This was performed at 2 P.M.; at 6 P.M. the patient had a shivering fit, and his temperature rose to 103·6° F., but by 11 P.M. it had fallen to 101·6°; on the 9th it was 100·4°, and after that kept between 99° and 100°, which indeed appeared to be his normal temperature, as it never sank below 99° except on one occasion. There is little to remark about the progress of the case. I employed a horsehair drain, which did not work perfectly, the result being that a little serum collected in the wound, and at one time there was a drop or two of pus. In consequence of this the progress was rather slow, the wound not being completely healed till four weeks after the operation. A slight pulsation was felt in the aneurism from the 11th to the 15th of September, but this completely disappeared, and by the time the patient left the hospital, on Oct. 14th, there was only a firm tumour of the size of a bantam's egg in the popliteal space. There was some tingling pain about the inner condyle, and occasional shooting pain at the inner and lower part of the thigh. No pulsation in the posterior tibial artery or dorsal artery of the foot could be detected.

---

[2] Text-book of Physiology, 3rd ed., p. 633.

I saw the patient from time to time after this, and watched the gradual diminution in size of the aneurism, which, when it had reached a certain point, became stationary, a small, hard, non-pulsating tumour remaining in the ham. In the early part of April, 1879, he began to complain of stiffness and coldness in the left calf, and on examination it was found that he had a small circumscribed aneurism in the ham on this side. His general health was now much better than it had been on the previous occasion, he having observed more temperate habits in the meantime. On Feb. 27th the circulation was completely controlled in the limb by means of an elastic bandage, applied over a flannel bandage, above and below the knee, the joint itself remaining uncovered. This was continued from 10.5 A.M. till 11.5 A.M., one-sixth of a grain of morphia having been given subcutaneously. The pain at last became unbearable, and it was impossible to continue the treatment without administering an anæsthetic; the bandage was accordingly taken off after screwing down a Carte's compressor three inches below Poupart's ligament. At 1.45 it was found that the tourniquet had slipped, and the aneurism was pulsating; it was relaxed for a quarter of an hour and then reapplied at 2.5 P.M., and the pressure was continued till 6.10 P.M., when it was finally removed. No alteration in the tumour had taken place. On the 28th a conical shot-bag was applied to the artery, so as almost completely to stop the circulation. The bag was slung from a bar, which passed over the bed, and the position was regulated by the patient himself. Its employment was begun at 10.45 A.M., and was continued almost without intermission till 7 A.M. on the 29th. After the bag had been applied for eleven hours the tumour seemed decidedly harder, and to be pulsating less, but when finally removed but little, if any, change from the original condition could be perceived. It is, of course, highly probable that the pressure was not efficiently applied during the whole of this period, as so much of the regulating of the position of the pad remained in the hands of the patient himself. A good deal of redness and tenderness of the skin was caused by the pressure of the shot-bag. On March 6th it was noted that the aneurism was decidedly larger and softer. At 1.48 the elastic bandage was reapplied without the previous application of the flannel bandage, so as completely to stop all circulation. One-third of a grain of morphia was given hypodermically. At 2.45 the pain had become unbearable, and the bandage was accordingly removed, the shot-bag having been previously applied; but as this was not quite in position at first, it was ascertained that the pulsation in the ham still existed. The pressure was continued efficiently till 10.40 P.M., when it was removed, and the pulsation was found to be less. On the 7th the shot-bag was again used for some hours without benefit.

As no effect was produced upon the tumour, which indeed was obviously increasing in size, I determined to ligature the vessel. This was accordingly done in the usual way, and with strict antiseptic precautions, on March 12th. The healing of the case went on very satisfactorily, and was complete, with the exception of a small superficial patch of granulations a quarter of an inch in diameter, by April 2nd. As in the previous operation, the drain did not act perfectly at first, and therefore the healing was not quite so rapid as might have been expected in an aseptic wound. The temperature reached 101° on the 12th, 14th, and 15th. On the 19th the maximum was 99°, and it did not afterwards exceed this limit. From the 20th to the 22nd very slight expansile pulsation in the aneurism was detected, which after this disappeared.

On May 17th the following note was taken:—Left leg: pulsation felt in femoral, below the seat of ligature, when the limb is extended, and sometimes a little in the popliteal space. A little hardness, in the shape of a stout cord, is felt in the ham, and a little pulsation can be detected apparently in this. There is a weak pulse in the posterior tibial. The nutrition of the limb is good. Some stiffness is complained of in the ham. On the right side no pulsation is felt in any part of the limb below the seat of ligature. The thickening in the popliteal space is decidedly less than when the patient was in hospital. The pain and stiffness are more than in the opposite limb.

On February 16th, 1881, two years and a half after the patient first came under notice, I made a very careful examination of the two limbs, and the following note was taken:—In the left leg (the second operated upon) the femoral artery can be felt pulsating as far as the upper part of the scar of the operation wound. Below this it is imperceptible, and, indeed, the only point at which any pulsation lower down in the limb is to be detected is in a vessel of some size which lies close to the inner hamstrings; the posterior and anterior tibial pulses appear quite deficient. Some occasional and indefinite discomfort is felt below the knee on this side, especially in cold weather; but this appears to be diminishing. On the right side, in the same way, the femoral pulse is not to be felt below the upper part of the scar; and here, again, only one vessel was, after a prolonged search, felt to be pulsating. This accompanies the external popliteal nerve to the head of the fibula, and is smaller and more superficial than that felt on the left side. No discomfort or pain remains in the right limb at all. On neither side is any trace to be discovered of the aneurism, the thickened cords mentioned in previous notes having completely disappeared. He says that in very severe weather his limbs feel a little more cold than was the case before the occurrence of the aneurism; but this is not enough to inconvenience him to any extent. His general health is now excellent.

Those who have watched the treatment of aneurisms by the various methods of compression in vogue, or who have read the published accounts of such cases, cannot fail to be struck with the fact that while in many instances the results are brilliant and in every way satisfactory, it not unfrequently happens that after submitting the patient to a prolonged and painful ordeal he is in no way relieved, if indeed his condition be not materially altered for the worse. For it must be remembered that after consolidation of an aneurism as the result of such treatment, gangrene of the limb is not by any means unknown; and not only so, but it is at least possible that the vessels and the surrounding tissues may have been, as the result of the pressure, placed in a less favourable condition for the application of the ligature than they were previously. The surgeon who has, as the result of experience, complete faith in the efficiency of the antiseptic system to prevent the various dangers which are incidental to the existence of the smallest open septic wound, and who knows that it is a matter of certainty that the small wound involved in the ligature of the femoral can be kept aseptic, would therefore, I think, hardly hesitate to tie the femoral without much delay in a case of popliteal aneurism if he were quite certain that the ligature employed was in every way trustworthy. Up to the present time this has unfortunately not been possible. We have several cases on record in which the ligature has no doubt yielded too soon, with the result of allowing the artery to become again patent; in some of which it may be presumed that the gut employed had not been sufficiently prepared, but in others it appears that the very best material to be had was made use of. The tests to which Mr. Lister has subjected the ligature, the preparation of which he has recently described, seem to show that it may be thoroughly trusted to withstand the softening effect of the tissues until the obliteration of the vessel has been completed, and therefore I, for one, shall feel little disposed to subject a patient to prolonged attempts at cure by compression. It has recently been suggested by Mr. M'Carthy and Mr. Treves that a certain amount of inflammation round the vessel is essential to the formation of a clot strong enough to withstand the force of the circulation. Cases such as mine, and many others which are on record, appear, in my opinion, to dispose at least of the universality of the truth of this position; and those who would argue in favour of allowing putrefaction to occur in the wound in order to ensure the amount of inflammation which is supposed to be necessary, will do well to bear in mind the following facts:—In the first place the existence of putrefaction is certain to accelerate the softening of the catgut ligature; and in the second place, it has been amply proved by the experience of generations that the inflammatory tissue is by no means always strong enough at the time at which secondary hæmorrhage is likely to occur to prevent the occurrence of this disaster. It is notorious that when hempen or silk ligatures were employed the danger of secondary hæmorrhage was real, and always present, but as far as I know it has never yet followed the application of the catgut when the wound has been kept aseptic to the last. It would seem therefore that even with the old imperfect material, a distinct advance had been made in the direction of safety, the inconvenience of the opening up of the vessel having been substituted for the danger of secondary hæmorrhage; it is surely fair to assume that with the improved means at our disposal, both the inconvenience and the danger will have been done away with, and we may now resort to the ligature with greater confidence than at any previous period in the history of surgery.

Wimpole-street.

THE PATHOGENY AND TREATMENT OF BRONCHOCELE OR GOITRE.

BY EDWARD WOAKES, M.D. LOND.

(Continued from page 450.)

AS already stated, the object of conducting the treatment in the present series of cases was to determine whether fluoric acid exercised any curative influence over goitrous diseases. The result—17 recoveries and 3 failures, or 85 per cent. of the former—gives what I think may fairly be considered an affirmative answer to this point. But it will be observed from the details that the treatment extended in most of the cases over a lengthened period of time—time that might not be accorded in other than hospital patients. In endeavouring, therefore, to estimate the position of fluoric acid as an anti-goitrous remedy, I certainly should not regard it for this reason alone, irrespective of its occasional failure, as occupying the position of a specific. It is to be regarded rather as a basis of constitutional treatment, with which iron in anæmic patients may be advantageously combined; while coincidentally with its internal administration recourse may be had to such local proceedings as experience has shown to favour the dispersion of goitre. It is matter of observation that when fluoric acid is adapted to a given case, its effect upon it is often immediate and rapid. As an illustration of this point I may refer to a young man who came under treatment at my out-patient clinic for the first time on Feb. 8th, 1881. He had a fibrous goitre of two years' duration, which was steadily increasing. Laterally it extended from the clavicles to the level of the hyoid bone on each side, while the isthmus was hard and prominent, the girth at this point being 16¾ in. He was given half-drachm doses of the acid three times daily. On his next visit, Feb. 15th, just one week, he volunteered the statement that the tumour had gone down half an inch, which on measurement proved to be the case. Perpendicularly the diminution was greater than this, the lobes now reaching only to the level of the cricoid cartilage. In such a case one would be content with the acid treatment. But there are others in which improvement goes on up to a certain point only, the peripheral portions of the tumour disappear, but its centre remains firm and large as ever. Then I should add the plan which originated with Professor Lücke, formerly of Berne and now of Strasbourg, and which has ever since been extensively practised at the Throat Hospital—viz., that of injecting the substance of the tumour with tincture of iodine. After this absorption recommences, and often it only requires to continue the acid, or a second injection may be necessary. The evidence points with certainty to this fact, that when fluoric acid is administered internally, but is insufficient of itself to cure the disease, the number of injections necessary for this purpose is materially diminished, a point not unworthy of notice by those who are nervous on the subject of injecting bronchoceles. On the other hand, some of the cases indicate that fluoric acid alone has proved efficacious, after injections and every other method had failed. From all these considerations it will, I think, be conceded that we have in this drug a valuable adjunct for treating diseases of the thyroid gland.

A brief recapitulation of the points already insisted upon will serve the purpose of indicating in what the *modus operandi* of fluoric acid and its allies consists regarded from a therapeutic point of view. The vessel area of the thyroid gland has become a part of least resistance, as regards the vascular system at large. This implies a fault not so much in the bloodvessels themselves as in the sympathetic ganglia which furnish the nervi vasorum of these thyroid vessels; the power which maintains them in equilibrium is thus to a great extent lost or exhausted. Hence they exhibit a very slight resistance to the blood pressure originating in the heart; they yield, in fact, to the *vis a tergo* of the blood current, and so receive more blood than normally should be the case. My contention is that the fluorine restores the lost contractile function to the impoverished ganglia, either by acting as a physiological spur to their function or, which is equally admissible, by furnishing a deficient element in their composition, one without which the nerve currents generated in them are reduced to *nil*. The supply of the missing element acts like the recharging of an exhausted galvanic cell.

CASE 1.—F. H——, a female, aged twenty, living at Camden-town, has had goitre for two years. In November, 1876, there was a fibrous enlargement of both lobes and isthmus, the right lobe being firmest and largest. The girth of the neck was 15½ in. Till July, 1877, she was treated with iron and iodide of potassium, with very little result. She was now given fifteen minims of fluoric acid (half per cent. dilution); but she almost immediately took typhoid fever. In March, 1878, she was again put on the acid, and in the three months following received altogether nine injections of tincture of iodine into the substance of the tumour. From June, 1878, the treatment was confined solely to the acid internally, the dose being increased gradually to thirty minims. In March, 1879, she was well, the tumour having disappeared. In February, 1880, she remained free from the disease. The period during which the acid was taken was nine months.

CASE 2.—C. P——, a female aged forty-seven, a governess, living at New Cross, presented on June 14th, 1878, a fibrous enlargement of the left lobe of the gland, of the size of a hen's egg, causing her considerable difficulty in swallowing. She began with twenty minims of the dilute acid three times daily on June 14th. On the 21st the swelling was much larger and softer, but she swallowed better; this enlargement is a good sign. On the 29th the dose was increased to thirty minims; on July 5th to forty minims; and on August 2nd to fifty minims. The tumour became softer and smaller gradually, and in November it had quite gone. The time of treatment by acid was six months.

CASE 3.—A. B——, a female, aged seventeen, a needlewoman living at Clerkenwell. She had soft goitre of the entire gland; girth 14 in. She began the fluoric acid with twenty minims on May 28th; in June thirty minims; in July forty minims; girth was now 13 in. This dose caused flatulence, so she took thirty minims to the end of the year; in January, 1879, fifty minims; in March seventy minims; in June she was well. Duration of treatment about twelve months. She had previously been blistered, and had undergone other treatment without benefit.

Case 4.—S. S——, a female, aged sixteen, a servant, living near Regent's-park. Disease commenced five years previously when living at Hertford, after suffering two accidents in quick succession. In August, 1877, she presented a goitre which extended nearly to the chin, in parts very firm, in others soft; girth 14½ in. During August and September she was twice blistered, and took iron, iodides, and bromides internally. She had also one injection of tincture of iodine. In October there was no improvement; dimensions as at first; she was given twenty minims of dilute fluoric acid twice a day. At the end of three months the girth was 13 in. In March, 1878, thirty minims; in April, forty minims. In May the girth was 12½ in., and the dose caused some sickness. In July the girth was 12 in. She continued the treatment to the end of the year, by which time the tumour had quite gone. Time, nine months.

Case 5.—L. S——, aged nineteen, milliner, living at Highbury. She presented in April, 1878, a simple, soft goitre of the entire gland; girth 13 in. There were also several enlarged lymphatic glands on the left sterno-mastoid. The disease had lasted one year. On April 23rd she was given twenty minims of dilute fluoric acid and one grain of sulphate of iron in an ounce of water three times a day. On May 14th the dose was increased to twenty-five minims, and on June 11th to thirty. This was continued till October, when the swelling had disappeared.—Note: Some swelling returned in the thyroid a month from this date after singing, but rapidly subsided. This fact bears on the foregoing remarks respecting the causes which bring about enlargement of the thyroid. Time, six months.

Case 6.—M. P——, aged sixteen, a nursemaid, living at Westbourne-park. She presented a simple, soft goitre of the entire organ, causing considerable dyspnœa. It had existed one year and a half; girth 13¾ in. On Sept. 4th, 1877, she was given fifteen minims of dilute fluoric acid. On Sept. 25th she breathed more comfortably, but had some headache. On Oct. 30th the tumour was receding, and on Nov. 13th there was marked diminution. Medicine caused sickness; to take half the dose. On Dec. 11th she was cured. Time under treatment, six months.

Case 7.—H. F——, aged fourteen, clerk, living at Camberwell; simple soft goitre. Was under a colleague from November, 1877, till April, 1878. He was transferred, for his own convenience, to the evening clinic. At this latter date the girth was 14 in., and the tumour reached the upper margin of the thyroid cartilage. On April 8th, 1878, began with thirty minims of dilute fluoric acid; April 30th, forty minims; May, fifty minims. The girth was now reduced to 12½ in. July, sixty minims. In September the disease remained stationary; the acid was discontinued, and he was directed to rub in red iodide of mercury ointment. This was withdrawn after a month's use, no effect being produced on what remained of the swelling. On Nov. 5th recommenced with thirty minims of fluoric acid; December, fifty minims. In 1879 there was marked improvement, especially in the perpendicular diminution. He continued the acid till June, by which time the gland was reduced to normal. The period during which the acid was taken was thirteen months.

Case 8.—C. W——, aged twenty-four, female, married, living in Long-acre; duration of disease six months. On June 7th, 1878, a tumour was presented in right lobe about the size of a walnut, and painful. Ordered twenty-five minims of dilute fluoric acid three times a day. On June 21st the tumour was smaller and free from pain. Given thirty minims of fluoric acid. On July 16th the tumour was still smaller. After this date the patient did not attend again. Practically cured; time six weeks.

(To be concluded.)

At Dorking several horses have been poisoned by eating the leaves of the yew-tree. The toxic character of the leaves of the Taxus baccata should by this time be well known.

BLOOD-CASTS WITHIN THE CAVITY OF THE UTERUS AS A CAUSE OF UTERINE HÆMORRHAGE.

By MATTHEW J. RAE, M.D.,
PHYSICIAN, BLACKBURN AND EAST LANCASHIRE INFIRMARY.

Hæmorrhage from the uterus, unconnected with pregnancy, is often very embarrassing to the medical practitioner on account of the frequency, extent, and persistence of the discharge, and its resistance to treatment apparently the most appropriate to the case. There are probably no diseases in which a thorough knowledge of the pathological condition of the part affected is more necessary to the practitioner than in those affecting the uterus and its appendages. Without such knowledge it is impossible either to have an exact idea of the state of the organ and the causes operating in the initiation or continuance of its disorders, or to devise the medical and surgical means necessary to remedy the existing defects and promote the return of the uterus to its healthy and normal condition. Systematic writers on the diseases of women, in their enumeration of the causes of hæmorrhage from the unimpregnated uterus, do not allude to blood-casts contained within the uterine cavity as a cause of it. Graily Hewitt is the only modern author, so far as I know, who makes mention of it, and only in a cursory way as a rare occurrence. Dr. Ashwell, in his valuable work on Diseases of Women, merely alludes to it as having occurred in one of his patients, a lady at the climacteric period, who suffered from congestive menorrhagia. He does not connect the protracted passive hæmorrhage with the blood-casts. There was scarcely any pain attending the attack, at least none requiring an anodyne to allay it. From the fact of a blood-cast as a cause of uterine hæmorrhage being so seldom recorded in works on uterine diseases, one might conclude that it was either a very rare occurrence or that it had been overlooked. I am inclined to think that it is not so rare, and that its presence has been often unrecognised, and the accompanying hæmorrhage attributed to some other local or constitutional cause.

The uterus is very intolerant of any foreign substance within its interior. A blood-cast generally excites severe uterine contractions, causing violent paroxysms of pain in the hypogastric region, of an expulsive character, and which show a certain periodicity in their recurrence. They resemble labour pains, or those of inflammation or severe spasmodic disorder. With the accession of a paroxysm of pain there is increased hæmorrhage. This state may continue for a considerable time, and probably lead the medical attendant to form various conjectures as to the exact nature of the case, thinking it may be some morbid growth attached to the inner surface of the uterus, an abortion, or even malignant disease of the uterus itself in its primary state. After the expulsion of the cast or blood-clot the violence of the pains subsides; but the hæmorrhage may go on, in a slighter degree, for some time afterwards. It may even continue, like the passive hæmorrhage in congestive menorrhagia, over one or two monthly periods, which renew its force and increase the hyperæmic condition of the already congested uterus. On digital examination the uterus feels more or less enlarged, and is tender and painful on pressure, frequently more so on one side than on the other. There is tenderness to the touch above the pubes, and generally also over one or other ovarian region. The speculum shows the os uteri swollen and patulous, with blood oozing from it. The blood-cast under consideration does not include that sometimes met with in menorrhagia or abortion, and it is probably formed somewhat in the following manner:—The subject of it during a catamenial period, when the uterus is in full functional activity, receives suddenly a severe mental or physical shock, which at once arrests the discharge, and paralyses as it were the uterus. After a time the effects of the shock pass off, and the uterus recovering its power a little, a slow oozing of blood takes place into its cavity. This gradually coagulates, and the coagulum is moulded to the form of the interior of the uterus. When the clot is expelled, it is found to be more or less an exact model of the uterine cavity, is smooth on the surface, and of varying degree of firmness, of a reddish and sometimes of an ashy-grey colour.

The best mode of treatment is first to remove the blood-cast, and afterwards to check the hæmorrhage, and relieve the congestion of the uterus. With this view, ergot in full and repeated doses should be given along with ipecacuanha, sedative solution of opium, or belladonna. Should there be great irritability of the stomach, a hypodermic solution of ergotin and morphia, or atropia, may be used instead. After the expulsion of the clot, ergot in small doses should be continued for some time, and combined with belladonna or cannabis indica and cinnamon, or the tincture of acteæ racemosa instead of the ergot, if the constitution of the patient is rheumatic. The ergot checks the hæmorrhage by exciting uterine contractions; but it lessens it also by its constringent effect on the capillaries, and thus tends to relieve the uterine congestion.

It is not always an easy matter to effect the cure of a highly congested uterus; this is partly owing to its position and partly to the peculiarity of its blood-supply. Some authorities recommend, in such cases, scarification of the os or the application of leeches to it. This plan of treatment does not seem to me at all rational. It is surely better to endeavour to determine the flow of blood from than to a congested organ. In active hyperæmia of the brain, or inflammation of its coverings, leeches are applied with effect behind the ears, or the cupping glasses to the nape of the neck or between the shoulders. On the same principle I think leeches should be applied to the labia, above the pubes, or over the insertion of the broad ligament of the uterus, as advised by Dr. J. Whitehead and others, or over the ovarian region or the sacrum, if these parts are the seat of pain.

Should there be great fulness of the hæmorrhoidal vessels or hepatic congestion, much advantage will be obtained by leeching round the anus. The extent of the hæmorrhage does not contra-indicate further depletion by means of leeches or cupping. Their judicious employment will be found of great service, along with appropriate remedies, both in checking the hæmorrhage and in restoring the congested uterus to its normal condition. Plugging the vagina will hardly ever be needed in these cases.

It may be necessary to give along with ergot, or without it, tannin, gallic acid, one or other of the mineral acids, or some astringent preparation of iron — the perchloride, pernitrate, tincture or sulphate with or without salines, combined according to the exigencies of the case or the predilections of the practitioner. With the internal exhibition of medicine, the frequent use of astringent and sedative injections per vaginam should be had recourse to. The skin and state of the kidneys demand attention, and the bowels must be kept open, as constipation tends to produce and maintain uterine congestion. For the hypogastric pain nothing answers better than either the compound chloroform and aconite liniment, or mercury ointment with extract of belladonna, applied over the affected part.

The patient ought to be kept in the horizontal position, and during the day to recline on a couch so soon as her condition will admit of her safe removal from bed. A regulated diet should be enforced, and all strong wines and spirits prohibited, unless there is great exhaustion, when small quantities of them may be cautiously given. In some extreme cases, where there is danger of fatal collapse setting in, a large quantity of these stimulants may be absolutely needed. But in the ordinary hæmorrhage from any form of congestion of the uterus my experience is that they are not required, and, if given, do harm by keeping up the hyperæmic state of the uterus. Instead of the heavy wines and spirits, Bordeaux or similar light wines may be allowed; they assist digestion and are refreshing, tonic, and slightly astringent.

By the employment of the means already indicated convalescence will be gradually established; and afterwards, by the proper use of alteratives and tonics (mineral and vegetable, both nervine and general), the cure will be effected and the general health re-established, which may be hastened by change of air and a course of chalybeate or other mineral waters.

Blackburn.

CHILDREN'S HOSPITAL, BRISTOL. — The annual meeting of this charity was held on the 19th inst. The report stated that of the 399 little patients admitted during the past year, 212 were restored to their friends cured, 128 were benefited, and 11 died. A new site for the hospital has been secured, and the committee are waiting hopefully for the funds necessary to enable them to construct a suitable building thereon.

OBSERVATIONS ON CASES OF

PNEUMONIA TREATED IN THE DIVISIONAL FIELD HOSPITAL, CABUL, 1879-80.

BY J. MORRIS, M.D.,
SURGEON, ARMY MEDICAL DEPARTMENT.

DURING the late campaign in Afghanistan thirty-five cases of pneumonia were under my care at Cabul, all of which belonged to a single Highland regiment. Disease in the greater number of cases was induced by overwork, combined with exposure to severe cold and want of sleep. A large proportion of cases was admitted during the first five days of January, 1880, partly due to reaction after the excitement of the siege. Several of the cases must have contracted the disease on New Year's eve, which is a great festival in Highland regiments. The barrack-rooms in Sherpur were very cold, being 60 ft. by 16 ft.; a small fire at each end had very little effect on the general temperature of the room. The floors were constantly damp, water being found about three feet from the surface. There was no attempt at ventilation. In eighteen cases the right lung was affected; in ten, the left; the remaining seven had both lungs implicated. Mortality, eleven, or 31·4 per cent. Double pneumonia, four fatal out of seven, or 57·14 per cent. Average duration of cases, eight to ten days before convalescence set in; average duration of fatal cases, 5·1 days. In many cases the disease was complicated with pleurisy, in one with remittent fever, and in three symptoms of meningeal inflammation were present for some time before death. Where death took place, it was usually the result of apnœa, the patients presenting the bluish appearance characteristic of non-aeration of blood. The disease was generally of the catarrhal or diffuse character. In four cases, where a single lobe only was affected, resolution occurred on the third or fourth day. In the earliest stage the treatment was tartrate of antimony in doses of a quarter of a grain every three hours, accompanied by large doses of potash, to render the sputa less viscid. As soon as the sputa could be brought up easily, carbonate of ammonia was substituted for the alkaline mixture, the antimony being still continued. As the disease was in the majority of cases of an extremely asthenic type, stimulants were exhibited at an early stage, gradually increased as needed. Sinapisms were applied daily over the lung affected. When dyspnœa became excessive, dry cupping over the front of the chest usually gave great relief.

I may remark, in conclusion, that the patients in the Divisional Hospital were supplied with every comfort in the way of food, wine, &c. The excessive severity of the weather was a large factor in causing the high rate of mortality. The thermometer frequently marked 28° to 30° of frost. I have seen it mark 20° F. for several successive days at 10 A.M. It can therefore be easily understood how impossible it was to keep up an equable temperature in wards hastily fitted up, with doors and windows fitting imperfectly, and little or no drainage.

SYMPTOMS OF CANTHARIDES POISONING DURING ITS INTERNAL ADMINISTRATION.

BY T. F. CLARKE, M.R.C.S. ENG., &c.

THE two following cases, exhibiting symptoms of poisoning by cantharides during the later treatment of gonorrhœa, may be of interest on account of the favourable result in each case.

I may preface my remarks by stating that in nearly every case of gonorrhœa for the primary symptoms—e.g., scalding, chordee, &c., with thick discharge,—I prescribe saline medicines and tepid-water injections. When the discharge becomes thinner, and all active inflammation has abated, I prescribe iron and cantharides internally (tincture of the perchloride of iron and tincture of cantharides, of each five minims, three times a day), and an injection of sulphate of zinc (two grains to the ounce). Such was the course followed in the present instances.

In the first case my patient had been taking the cantharides mixture for five days, at the end of which time he was virtually cured. A week after the discontinuance of the medicine I was summoned to him for violent pain over the bladder, and this was accompanied on the following day with strangury. These symptoms, at first very severe, passed off at the end of about four days, during which time I gave him nitric ether and hyoscyamus internally, and ordered hot baths whenever the strangury came on.

In the second case the patient, after taking two doses only of the cantharides mixture, had some of the symptoms of poisoning—viz., frequent desire to pass urine, burning pain during micturition, which was very difficult, and always accompanied towards the end of the process by a few drops of blood. I ordered him to take only half the dose, but these directions were not followed, and he continued with the full dose, the symptoms, nevertheless, rapidly abating.

In each case every trace of the gonorrhœa was removed, and as soon as the active symptoms produced by the cantharides passed off, the patient felt as well as ever, and had not the slightest discomfort in the urinary organs. Why these symptoms of cantharides poisoning should have presented themselves—for I frequently administer the drug in much larger doses, and without any untoward symptom—I am at a loss to understand. The delay of the symptoms in the second case may, I think, be explained by the supposition that the drug became stored up in the kidneys, and that after a short time its cumulative action gave rise to the poisoning symptoms.

WESTMINSTER HOSPITAL.

ANEURISM OF ASCENDING AORTA OPENING INTO A FALSE ANEURISM BETWEEN THE ASCENDING AORTA AND STERNUM; APPARENT IMPROVEMENT UNDER LARGE DOSES OF IODIDE OF POTASSIUM; DEATH.

(Under the care of Dr. STURGES.)

FOR the notes of the following case we are indebted to Dr. W. Gristock, medical registrar.

E. D——, aged fifty-five, a stableman, was admitted on Sept. 28th, 1880. He had previously drunk a good deal of rum; had rheumatism once several years before; no history of syphilis; had been much exposed to the weather, and had often had insufficient nourishment. He was in the hospital first in May, 1877, with evident aneurism of the aorta, with distinct pulsating bulging in the second right intercostal space. Though he had since then been in different hospitals over and over again, he had been able to do a little light work at times. The last time he was in Westminster Hospital was in 1878. The signs of aneurism were most marked, but under large doses of iodide of potassium and rest, both the symptoms and physical signs subsided very considerably, the tumour becoming apparently solid. During the summer of 1880 he did light work and lived badly. He caught cold a month before admission, and became much worse. He had much aching pain in the right axilla and down the right arm, and his hand felt numb. He had also some pain and numbness in the left arm, which was never previously affected. He had occasional dysphagia for liquids, some dyspnœa—"a choking sensation." During the week before admission pain in the back came on. The appetite was good, the bowels were rather constipated, but there was no sickness.

On admission there was orthopnœa, with especial difficulty in lying on the left side. There was slight working of the extraordinary inspiratory muscles, stridulous breathing, and aneurismal cough. Pain was complained of in the back between the shoulder-blades, and there was dysphagia. The heart's apex beat was two inches and a half below, and an inch outside the nipple in the sixth space. There was visible and distinctly expansile pulsation to the right of the sternum reaching from the lower border of the second rib to the upper border of the fourth rib. Dulness extended from the first space to the fifth rib, reaching two inches and a half to the right of the sternum, and slightly across the sternum. The right margin of the sternum was tilted up. There was no apex murmur, but a double murmur was heard over the tumour. There was a distinct thrill in both carotids; no particular enlargement of the superficial veins of the chest was discernible, but the jugulars were prominent, especially the right, and the veins of the left arm were more prominent than those of the right. There was no pulsation in the back. Hollow respiratory sounds were audible over the root of the right lung, as if from pressure, and there were a few moist râles.

By Oct. 5th the patient was easier, and slept fairly well. A fortnight later, after cold, foggy weather, the dyspnœa had increased, and also the dysphagia, and the patient's sleep was very disturbed. The heart's impulse became very indistinct, probably by becoming covered by lung. On Oct. 16th the pulsation was distinct at two points to the right of the sternum, as if there were two centres of pulsation. The pain in the back became more severe, and the patient also complained of pain in the right side of his throat, increased by swallowing. The bowels were also very confined; the pain was relieved by ice, though unaffected by fomentations. By the end of November the pain was much worse, not being so much relieved by ice. The dysphagia varied at different times, but there was a good deal of cough, which caused a "tearing pain." By the beginning of December there was acute pain in swallowing, with symptoms of pressure on the œsophagus. Orthopnœa increased towards the end. The temperature, when taken, was about normal or subnormal throughout till Nov. 30th, when the patient had a rigor, after which the temperature was febrile: 102·6° on the evening of Nov. 30th; 100° to 101° afterwards; pulse 96 to 100. The treatment consisted of iodide of potassium, in twenty grain doses, with bromide of potassium and chloroform, three times daily, from Oct. 13th to Nov. 5th, when it was omitted for a few days, then resumed. After Nov. 30th twenty grains of iodide of potassium, simply in an ounce of water, were taken three times a day. Besides this, expectorant mixtures and sedatives were required, and frequent purgatives.

Necropsy (*abstracted from the notes of* Dr. HEBB, *the pathologist*) *nineteen hours after death.*—Body warm; rigor mortis well marked; an elastic tumour, about the size of a florin, in third right interspace, immediately adjacent to sternum; dulness on both sides in front from lower border of third rib downwards; the sac of the aneurism intimately adherent to sternum over an area of about two inches and a half in diameter; the veins at the root of the neck were much dilated and gorged with blood. The thoracic viscera were removed *en masse*. There were slight adhesions at left apex and anterior surface of right lung; lungs gorged with frothy serum, but otherwise normal. The pericardium was distended with clear yellow serous fluid. The heart was enlarged as a whole, mainly owing to dilatation of the right cavities, especially the auricle, but there was also slight hypertrophy of the left side. The right auricle was choked with whitish-yellow clot, and there was yellow clot in the other cavities. Aortic valves atheromatous, but competent; the other valves were normal, but the tricuspid orifice was dilated. Aorta atheromatous throughout, and ascending and transverse portions dilated enough to admit the closed fist. The dilated part bulged chiefly to the right. There was an opening about the size of a shilling in the anterior wall of the ascending part. This opening communicated with a sac lying between the aorta and the sternum, and was adherent to the latter. The anterior and lateral portions of this sac were lined by laminated clot, the external part of which (about a quarter of an inch in thickness) was tough and evidently old. The more internal layers were softer. The posterior wall of the sac was formed by the aorta. It was smooth, yellow, and not covered by clot. The fourth dorsal vertebra was eroded, rough, and of purplish colour on its anterior aspect; and the sternum adjacent to the anterior sac was injected, purplish, swollen, and spongy. There were several dilatations of the abdominal aorta, the largest being just below the bifurcation on the right common iliac artery. There was another aneurism of the superior mesenteric artery, three inches in length and nearly one in diameter.

The coats were rough from atheroma, and the sac contained black clot. The laryngeal cartilages were ossified; cords normal. No apparent pressure on the trachea. The liver weighed seventy-four ounces, dark purple, but tissue normal. The spleen weighed nine ounces, and was adherent to the diaphragm. The right supra-renal body was adherent to the liver. The kidneys weighed five and five and a half ounces respectively, capsules adherent, granular surface, much diminished cortex; tissue congested.

Remarks.—This case is interesting as regards the apparent effect of iodide of potassium. During the patient's last stay but one in the hospital in August, 1879, under large doses of iodide of potassium, combined with rest and good food, he showed material improvement in general symptoms, while, at the same time, the pulsation and prominence of the tumour subsided. The iodide had no such effect in the last illness, and the results of the post-mortem examination showed a condition of the parts in which the tempory improvement could be easily accounted for without any special action of the iodide.

MONTGOMERYSHIRE INFIRMARY.

CASE OF DISLOCATION OF THIGH, WITH PERSISTENT LENGTHENING OF LIMB AFTER REDUCTION.

(Under the care of Dr. PRATT.)

J. P——, carter, aged thirty-five, was admitted on the 13th November, 1880. On examination he was found suffering from dislocation of right thigh. According to the man's own account he was knocked down by his horse in the street, and being picked up was found unable to stand, and was consequently carried to the infirmary. The dislocation was easily made out. There was inversion of the foot, with very slight shortening, pointing of the right great toe over the ball of left great toe, and, as the patient was by no means stout, the head of the femur could be felt in its new position, lying deep in the sciatic notch, almost upon the spine of the ischium. The man was at once put under chloroform, and upon manipulation the head of the bone glided below the acetabulum into the thyroid foramen. Thence it was easily dislodged, when it went back to its old position. The flexion upon the abdomen was now made more complete than at first, and whilst the limb was being everted and extended, the head was slightly lifted up, when it went into the cotyloid cavity with an audible snap, and the limb was easily placed alongside the other. But now the limb was found to be half an inch longer than its fellow. Nevertheless it was all right in the acetabulum. What was the cause of this lengthening? Was it a quantity of effused blood and serum into the socket, causing the head to protrude, or was it owing to paralysis of the muscles? The latter was thought to be the right cause, and upon its disappearance the limb would no doubt be the same length as the other. The knees were accordingly bound together, and the patient left comfortable in bed. On recovering consciousness he professed to feel quite right, but upon being questioned declared that as far as he knew his two lower limbs were always of the same length. In a few days much discolouration appeared upon the pelvis and thigh, proving that much blood had been extravasated. This gradually went away in a fortnight, and perfect movement of the thigh in all directions was recovered, but still the lengthening of half an inch persisted. In the third week he was up, and walking about with a slight limp. He went out and returned to his old work. He was seen about a month afterwards, when he declared that he walked as well as ever. He knew no difference between his walking now and what it was before the accident. He was taken into the infirmary and measured, when the injured limb was found still to be nearly half an inch too long. The only conclusion that could be now arrived at was that here was a case of congenital difference in length between the two limbs. It is worth recording, on account of its rarity and on account of its early puzzling character, which raised a doubt whether the dislocation had been properly reduced.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES. Mr. Robert Ross, late of Glasgow, bequeathed £1000 to the hospital at Dingwall, erected in commemoration of his friend and kinsman, Dr. Wm. Ross.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Innominate Aneurism treated by Simultaneous Distal Ligature of the Carotid and Subclavian Arteries, with remarks on the behaviour of a Tendon Ligature.

THE ordinary meeting of this Society was held on the 22nd inst., Dr. Barclay, President, in the chair. One paper occupied the evening. It was by Mr. Dent, of St. George's Hospital, and dealt with a subject which has been before the Society twice this session—the question of animal ligatures. An interesting discussion arose, in which two points were raised—viz., as to the efficacy of such ligatures in occluding the artery, and as to the precise nature of the "organisation" of the ligature.

A paper was read on a "Case of Innominate Aneurism treated by simultaneous distal ligature of the carotid and subclavian arteries, with remarks on the behaviour of a tendon ligature," by Mr. C. T. DENT. The chief object of this paper is to describe the changes observed in an artery tied with a tendon ligature. The parts were examined ten days after death. The history of the case was as follows:—S. L——, an engineer, aged thirty-seven, was admitted with an aneurism of the innominate artery, the first symptoms of which had been noticed about twelve months previously. He improved at first under rest and iodide of potassium, but then as the growth increased the carotid and subclavian arteries were ligatured subcutaneously by Mr. Pollock. For the carotid artery catgut was employed as well as the tendon ligature; the subclavian was secured with a flat tendon ligature only. Both arteries were healthy. The aneurism improved, but the patient had at times very severe attacks of dyspnœa, and died ten days after the operation. A large ulcerated opening was found in the trachea, which did not communicate with the cavity of the aneurism. The carotid artery was dissected out and examined; the following points were observed:—A very moderate amount of lymph was effused about the tied artery, though sufficient to bury the knot of the ligature. Well-formed clots were found in the proximal and distal ends of the completely obliterated vessel. No trace of the catgut ligature could be found. Much of the tendon ligature, where not in contact with the artery, was unaltered. The external coat of the artery was not ulcerated. This the author ascribes partly to the fact that tendon, like other animal ligatures, is capable of slight softening and swelling, and partly to the fact that new bloodvessels are early developed in parts lying close to the artery. The inner coats of the artery were ruptured. The tendon ligature, in many of the sections, was in most close connexion with the artery, and in these places was infiltrated with small round granulated cells, which in places split up the fibrous material into longitudinal bands. Some of the cells seem to be more elongated than others. In connexion with these cells, and formed by them, were seen new bloodvessels. Here and there it appeared possible in the sections to trace bloodvessels passing across the line of connexion, extending into the artery on the one hand, and into the tendon on the other. In conclusion, the author states that though he did not share in the objection urged against catgut ligature, still it seemed that tendon might furnish an animal material which would require less preparation than the carbolic or chromic catgut ligature, and which would probably be more constant in its behaviour.—Mr. BRYANT said the question of the use of flat ligatures involved the important principle whether it were necessary for permanent occlusion that the inner and middle coats should be divided, the point established by Dr. Jones; and he had himself some years ago come to the same conclusion that permanent occlusion could only be thus obtained. The flat ligature, which only compressed the vessel, would cause simply a temporary occlusion, long enough in some cases to allow of coagulation in an aneurism, but not in the other more difficult cases where ligature had to be resorted to. He compared the action of the flat ligature to that of acupressure, which had been almost abandoned because (in the case of severed arteries) it was frequently followed by secondary hæmorrhage, the vessel not being occluded long enough to allow of permanent clotting. Hence those cases of aneurism which could not be cured by other means of compression were not suitable for the application of the flat ligature. A similar mode of temporary obstruction was devised by Mr. Dix of Hull some years ago, consisting in a wire loop placed round the artery and secured over a piece of cork. He thought much evidence was required before the fact of organisation of an animal ligature could be admitted. He had examined six or seven vessels some weeks after ligature by carbolised or non-carbolised catgut, and although he had seen new vessels around the material he could not believe they had been formed at its expense.—Mr. **Savory** thought it strange if dead matter could be converted directly into living tissue. Several years ago it had been shown that masses of dead tissue introduced into the living tissues became infiltrated with leucocytes; but the inference was that the leucocytes had proceeded from the irritated living tissues, and had absorbed the dead material. In Mr. Dent's case new vessels appear to have formed in the dead substances. The same criticism was applicable to the subject of organisation of blood-clot about which so much had been heard lately. John Hunter studied it, and some of his specimens were in the College of Surgeons' Museum; but in his cases he dealt with living and not dead clots. It was different in the case of large masses of blood-clot in wounds, masses which must be inert and act as foreign matter; which could not organise, but which might be replaced by new tissue proceeding from the living parts around. If an animal ligature could organise it would be important to know from what source it was prepared, and whether it was old or recent.—Mr. **Holmes**, from his own limited experience, had arrived at a different conclusion about the efficacy of animal ligatures to that of Mr. Bryant. He fancied Mr. Barwell had slightly exaggerated the difference in the action of a ligature of flat shape as compared with a round one; for he (Mr. Holmes) had been able on the dead subject to divide the internal and middle coats partially or completely by means of the flat ligature when tied sharply. In the two cases in which he had tried Mr. Barwell's ox-aorta ligature the vessel was permanently occluded, one was a case where he had tied the iliac for rapidly enlarging iliac aneurism with good result; the patient was long under observation (requiring two amputations before his discharge), but the aneurism remained perfectly occluded. In another case, where the patient died in consequence of a debauch two weeks after operation, the ligature was found firmly attached to the artery, which was quite closed. In a third case, where two arteries had been tied, they were found occluded by a diaphragm, as in Mr. Treves's case, the ligatures having disappeared. The evidence, so far as it goes, is in favour of the permanence of these ligatures, and that an artery may be safely occluded whether the material used be oxen aorta or tendon. It had been explained that the ligatures did not themselves become organised, but that they disappeared, and were replaced by a ring of fibrous tissue. That such a replacement was not peculiar to healing under antiseptics was shown by this case of Mr. Pollock's and Mr. Dent's, where no antiseptics were used. It seems that these animal ligatures may be invaded by leucocytes and caused to disappear, new tissue taking their place; and this is now allowed by Professor Lister to be what is meant by "organisation" of the ligatures. So also in the case of blood-clot, the actual organising elements and new vessels being supplied from the surrounding tissues, the walls of the arteries, &c., surrounding the clot. It is quite possible that an animal ligature may excite this formative influence, and its results could not be compared with the effect produced by acupressure.—Mr. **Barwell** was not sure that inert matter would not take on vital properties again, and thought that skin-grafting was an instance in point. In a recent case of a large burn, where the "grafts" did not take on the granulating surface, he had found that minute portions of the inner coat of the ox's aorta placed on the surface became converted into a distinct epidermis, others of them melting down into pus. He reminded Mr. Bryant that at the last meeting of the Society he had recorded twelve cases in which perfect occlusion had followed the use of the oxen ligature, and had been able to show the specimens from two of these cases; so that the flat ligature in no way resembled acupressure in its effects. The question as to the need for the division of the inner and middle coats was different now than when Dr. Jones wrote, for at that time ligatures were used which subsequently came away by ulcerating through the outer coats. Now, however, we have ligatures which can be left on the vessels, and which do close arteries permanently. It was essential that the animal ligature, whether tendon or not, should be used first, or should have been dried when fresh; for if putrefaction take place in it its characters are altered and its efficacy impaired.—Dr. **B. O'Connor** said that a short time ago he examined microscopically a mass of lymph lodged at the inner end of a drainage-tube, which had been removed by Mr. Lister. This lymph, which was not in contact with living tissue, contained distinctly small vascular branches. In reply to Mr. Page, he added that the drainage-tube had been *in situ* about four days.—Mr. **Dent**, in reply, said that the discussion showed that questions were still unsettled which had been thought to be determined by Dr. Jones. He mentioned that in one of Dr. Jones's experiments a septum was formed in the artery precisely like that lately described by Mr. Treves in a vessel tied by the carbolised catgut ligature. In the present case there was microscopical evidence that the inner coat had been ruptured, and that the artery was permanently occluded. In the subclavian artery, where only a tendon ligature was applied, the clots were not so large and well-formed as in the carotid, where two ligatures, one tendon and the other catgut, had been used. As to "organisation," one of the specimens showed vascularising lymph between the two occluded ends of the artery, at a distance from the tendon ligature; and he believed the view taken by Mr. Savory and Mr. Holmes was probably the true one. Mr. Stirling, who had brought these kangaroo tendon ligatures from Australia, had selected them because of the readiness with which they were prepared. Ligatures of whale tendon had also been suggested. Mr. Dent had used them as sutures, and found them too thin and too readily dissolved in the tissues. There was no reason why the same material should not be used as a round rather than a flat ligature; the great advantage claimed for it over catgut being the time it remains unabsorbed.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

President's Address.—Pseudo-hypertrophic Paralysis.

At the meeting on the 14th instant the chair was taken for the first time by the newly-elected President, Dr. **Broadbent**, who delivered an opening address, in the course of which he recommended the Fellows to be ever jealous for the welfare and reputation of the Medical Society, and remarked that if, by any chance, the Society should cease to exist, it would become a positive necessity that another society, formed on similar lines, should at once be set on foot. He mentioned that the objects of the Society were general, and they therefore required not only the experience of the hospital physicians and surgeons, but also that of the general practitioner, who was here enabled to bring forward each week notifications of the morbid processes met with in his practice, and relate them to the Fellows, details which gentlemen of the former class were quite unable to supply. He said—"There is a want of opinion on all subjects from all professional sources, and such a want this Society supplies. Such reports as are received must, of necessity, influence both our views and our practice. Moreover it is the duty of the seniors to place the results of their experience before the juniors, and it is the privilege of juniors to hear and derive profit from them. The present time is the seed time for the younger practitioner; a thought planted in the brain, flowers and bears fruit almost unconsciously." He invited Fellows to bring forward communications for the advancement of medical science.

Dr. **Dowse** then exhibited a patient suffering from Hypertrophic Paralysis. The father and mother were both healthy; the patient, a boy of eleven, was a delicate, sickly-looking lad, one of five children, three of whom had died of bronchitis. The mother stated that when a child the boy was always backward in getting about, fairly intelligent, but weak about the loins, and not able to walk like other children; she also noticed his calves were harder and larger than they should be, whilst the other muscles of the body were wasting away. Dr. Dowse drew attention to the history of this disease and to its pathology, observing that the following points were essential to diagnosis:—First, peculiar gait of the patient both in walking and standing, the hip and lordosal spine being more or less fixed and erect, the boy walking upon the toes owing to the contraction of the Achilles tendon; secondly, the enlarged and hardened condition of the muscles of the calves; thirdly, the instability of the normal equilibrium of the body; and, fourthly, the peculiar way in which the lad raises the body from the prone to the erect position by placing the hands upon the knees and thighs, progressing from below upwards.

Dr. RADCLIFFE CROCKER showed a case of Pseudo-hypertrophic Paralysis, which had been under his care at the East London Hospital for Children from within three months of the noticed commencement of the disease until the present time—a period of eleven months. The patient was a boy aged seven years and a half, in whom the disease commenced at the age of six years and nine months. When first seen on July 31st, 1880, he could get up from the floor as readily as a healthy boy, but he was always falling down, mostly forwards. He stood with his knees a little bent, and his head slightly thrown back; his left foot dragged a little when he walked, and his calves were large and hard. Mentally he was normal, and physically well nourished. He was the fourth child; the three previous had died before they were twelve months old, but not of any nervous disease. There was no history of similar disease in the family. He was not seen again until Dec. 6th, 1880. Both legs now drag distinctly, but the left more than the right. He could still get up very well, but the knees were more bent. The left calf measured 9¼ in., the right 10 in. There was very little change in electrical reaction. The muscles of the calf reacted rather more readily to the anode than to the cathode of the galvanic battery. On March 14th, 1881, the bending of the knees was much more marked, and there was slight but evident lordosis; his walk was more shuffling, and he had rather more difficulty in getting up from the floor, but does not "climb up his knees." The measurement of the calves is the same, and the patellar tendon-reflex is still normal. Noteworthy points were the comparatively late age, considering the sex, of the commencement of the disease, the early stage at which it was first seen, and the rapid progress it was making, together with the good general nutrition.—Mr. WILLIAM ADAMS remarked that the case of Dr. Dowse was most characteristic of an interesting but at present little understood disease. Years ago he had divided in many such cases the Achilles tendon. The patients were generally small children; one of the first came under his care in 1867. Many of them are reported in the Transactions of the Pathological Society, vol. xix., 1868. Dr. Duchenne had regarded them from an electro-therapeutic point of view, he himself from an orthopædic. Mr. Adams stated that an interesting report of one of the latter character was published in the Transactions of the Medical and Chirurgical Society by Dr. Lockhart Clarke.—Mr. HENRY BAKER had treated these cases by a strap round the instep, which was successful as regards the tripping.—Dr. JAGIELSKI called attention to the increased size of certain of the muscles; he knew of two families in which there had been weakness of intellect associated with pseudo-hypertrophic paralysis. Faradisation, phosphorus, and strychnine had failed in his practice, and he would like to know from Dr. Dowse whether such patients demonstrated mental imbecility.—Dr. BROADBENT reported a notable instance in which the form of paralysis had attacked two girls in a family of three, whilst the boy was the subject of epilepsy. One important feature was wanting in this case—viz., hypertrophy in any of the muscles, though they presented characteristic symptoms. The disease in this case commenced as late as sixteen years of age. Hypertrophy was, perhaps, a symptom in the beginning of the disease.—Dr. GILBART SMITH hoped Dr. Dowse would state if he considered these cases of hypertrophic paralysis as instances of Duchenne's disease, as the latter name seemed to be applied to other nervous affections by many.—Dr. DOWSE said he did not recognise any special association between the physical and mental disease, especially in its early state, and he hardly called these cases of Duchenne's paralysis.—Dr. CROCKER alluded to the fact of there being a Duchenne's disease and a Duchenne's paralysis, and was inclined to think that there was frequently an association between the muscular and mental disease. He gave an unfavourable opinion as regards time in his case, as the disease had been making rapid progress during the last six months.

Reviews and Notices of Books.

Syphilis and Marriage. By ALFRED FOURNIER, Professeur à la Faculté de Médecine de Paris; Médecin de l'Hôpital, St. Louis. Translated by ALFRED LINGARD, M.R.C.S. With Prefatory Remarks by JONATHAN HUTCHINSON, Esq., F.R.C.S. London: David Bogue. 1881.

PROFOUNDLY interesting as are all the problems in connexion with syphilis, whether pathological, clinical, or therapeutical, their importance is intensified when the question of marriage is considered in the very many relations in which syphilis affects it. The rules at first laid down to guide the profession in this matter have proved in one particular disastrously misleading, for it is not the case that only the primary manifestations of syphilis are contagious, and that marriage is proper at any time after the subsidence of the early period of the disease, nor, on the other hand, is it true that marriage is unallowable at any period after contracting the disease. Neither of these extremes being correct, it is a difficult matter to hit upon just that happy mean between them that avoids the dangers on every side. There are few, if indeed any, who are so well qualified to speak on this subject as M. Fournier, and the English speaking part of the profession is under a debt of gratitude to Mr. Lingard for translating these valuable lectures.

Fournier first discusses the dangers imported into marriage by syphilis, and divides them into: (1) dangers to the wife of direct infection from a syphilitic husband, or infection from a syphilised fœtus; (2) dangers to the children of direct infection, of death of the ovum, fœtus, or child soon after birth, and of degenerative affections interfering with the robustness of the individual, apart altogether from the more special forms of syphilitic inheritance; and (3) dangers to the husband of serious or fatal tertiary manifestations. Having considered the danger of improper marriages, the next lecture is devoted to a discussion of the conditions under which a syphilitic man becomes fit for marriage, and these, stated very briefly, are as follows:—1. Absence of actual specific symptoms. 2. Advanced age of the diathesis, at least three or four years devoted to methodical treatment. 3. A minimum of eighteen to twenty-four months of immunity after the last specific manifestations. 4. A mild form of disease and absence especially of affections of the eye and nervous system. 5. Thorough specific treatment carried out in a methodical manner for a sufficient length of time. The minimum period of time of freedom from symptoms, and of duration of the disease under methodical treatment, is longer than that usually insisted on in this country, and Mr. Hutchinson, who writes the preface, while on the whole endorsing the author's views, suggests that his rules are fairly capable of some relaxation; it is, moreover, necessary to consider every case separately on its own merits, and not to be too much influenced by hard and fast standards. The third lecture is devoted to a consideration of the proper management of the various conditions brought about by syphilis present in one or both of a married couple. The various problems that arise when syphilis has extended into a family are stated with admirable clearness, and the lines laid down for treatment are such as must commend themselves to those acquainted with the management of these cases.

M. Fournier is firmly convinced that a child may inherit syphilis from the father only, the mother remaining healthy, and he believes that such a fœtus may subsequently, while in utero, infect the mother.

There is a question of medical ethics introduced to which it may be well to refer for a moment. In discussing the surgeon's duty when called upon to treat a wife recently infected by her husband, M. Fournier lays great stress upon the paramount duty of concealing from the wife, at all costs, the real nature of her malady. And then he goes on to point out the difficulty and oftentimes the impossibility of this course, and that by concealing its nature we are often deprived of our only chance of treating the case successfully. Now, although the surgeon should never voluntarily or carelessly lead to an exposure of the errant husband, it is well to bear in mind that our duty to the wife is our patient is paramount, and that wilful and direct deception can never be justified. The old attempt to attain good ends by bad means is as disastrous in medicine as in social relations. We can only add that the translation is well done, and the book very creditably got up.

The New Playground, or Wanderings in Algeria. By Alexander A. Knox. London: Kegan Paul and Co. 1881.

This is a gossipy book, written partly, probably, to kill time during a winter's exile in Algiers, and partly for the information and amusement of others. The chapter on the climate of Algiers, written "for invalids," is the only one which has special interest for our readers. Judging from a record kept at the military hospital for the thirteen years preceding the winter of 1879–80 it appears that during the six winter months the average mean temperature was for October 68½° F., November 60°, December 55°, January 59°, February 55½°, and March 57°. Only once in the month of January did the thermometer descend to 32°, and the difference between the average maximum and the average minimum in these thirteen years was 14½° in October, 12½° in November, 13° in December, 12½° in January, 13½° in February, 14° in March, while the average maxima registered were 75½° in October, 66½° in November, 61½° in December, 60½° in January, 62° in February, and 64° in March. The sunlight is practically always at a maximum, and during Mr. Knox's sojourn he spent on an average five or six hours per diem in the open air. Ice was not seen during his stay, and be it remembered that his residence, in the suburb of Mustapha Supérieur, was 600 ft. above the sea level. On one day there was a terrible dust-storm, but only one.

The drainage of the town of Algiers is not of the best, and many of the houses are haunted by bad smells. Among the villas of Mustapha Supérieur the drainage is said to be better, and in 1879–80 Mr. Knox heard of six cases of typhoid occurring among the English residents of that locality. The accommodation at Algiers appears at present to be inadequate. The hotels are not to be compared with those on the Riviera, and the rental of villas for the winter months is rather high, varying from £200 to £500.

THE ROYAL UNIVERSITY OF IRELAND.

The following are the arrangements for the medical portion of the curriculum as proposed by the committee appointed for that purpose by the Senate:—

In Medicine the degree of Bachelor of Medicine and Doctor of Medicine will be conferred; in Surgery, that of Master of Chirurgery; and in Obstetrics a special diploma. The course for the degree of M.B. and M.Ch., and the diploma in Obstetrics, shall extend over at least four years, and shall be divided into periods of at least two years each. Candidates will be required in addition to the ordinary first university examination to pass the following professional examinations—viz., first professional examination, second professional examination, and the degree examination, while candidates for the M.D. may present themselves at the examinations for this degree at the end of two academical years from the date of obtaining the degree of M.B. The fee for the first professional examination will be £1, and the subjects for examination zoology, botany, and a modern language. Candidates who pass with honours, and whose aggregate marks entitle them to a first class will receive exhibitions of £35, and those whose aggregate marks entitle them to a second class will receive exhibitions of £20. The second university examination in medicine comprises anatomy, physiology, materia medica, and chemistry, and the fee for the examination will be £1. The examination for the M.B. degree will comprise the subjects recommended for study during the second period of medical study —viz., anatomy and physiology, practical anatomy, theory and practice of surgery, midwifery, theory and practice of medicine, medical jurisprudence; also examinations in clinical medicine and surgery. Candidates who pass with honours and obtain a first-class certificate will receive exhibitions of £60; a second-class, exhibitions of £40. The fee for this examination will be £3. The degree of Master of Chirurgery will be conferred only on candidates who have obtained the degree of M.B. of the University; and the examination will comprise the theory and practice of surgery, including operative and clinical surgery. The fee for this examination will be £5. The examination for the diploma in Obstetrics will be conferred only on candidates who have obtained the degree of M.B. of the University. The fee for the examination will be £2, and the subjects will comprise the theory and practice of midwifery, and the use of obstetrical instruments and appliances. The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degree of Bachelor of Medicine, and has been engaged for two years in hospital, or private medical or surgical practice, or in the military or naval medical service. The candidate must also furnish a thesis, which will not be approved unless it contains some original or personal observations in practical medicine, surgery, midwifery, or in some of the sciences embraced in the curriculum, or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise reference to the publications quoted. All certificates of attendance at lectures must expressly state the absolute number of attendances at lectures of the individual student, and no such certificate will be received by the Senate unless it show a *bonâ fide* attendance of two-thirds of the whole course. All degrees in the University will be open to persons of either sex; but the examinations for women will be held apart from those of men, but will take place upon the same days. The Committee recommend that the University Buildings shall be situated in Dublin.

THE HIGHER QUALIFICATIONS OF THE IRISH BODIES.

To the Editor of The Lancet.

Sir,—The exact position of the Royal College of Surgeons in Ireland, in respect to its highest qualification, has not, as far as I have seen, been distinctly stated in any of the leaders and letters which have appeared in your columns.

This body possesses the power of granting an honorary Fellowship, but it has been so sparingly exercised that at present but seven such Fellowships are in existence, including such names as William Bowman, George Gulliver, and others of equal standing; with these exceptions the Fellowship has never been granted without examination since the date of the last charter in 1844.

I am not so well acquainted with the regulations of the King and Queen's College of Physicians; but I believe that their Fellowship, though given by election, is granted under very stringent regulations, and only to those holding the highest position as physicians, and is almost entirely confined to gentlemen practising in Dublin.

I am amongst those who think that, except in very rare instances, the higher qualifications should never be granted otherwise than by examination; but that the examinations, though very thorough, should be chiefly practical, and granted only after some years of practice; then would result a selection of the most hard-working and energetic men; and to such men the attainment of a higher examinational grade would prove a stimulus of great value.

I am, Sir, yours &c.,

March, 1881. One Interested in Medical Reform.

THE LANCET.

LONDON: SATURDAY, MARCH 26, 1881.

The helplessness of the Local Government Board in respect to small-pox, and the arrangements for the control of that disease, are, if possible, becoming more and more humiliating. Questioned in the House of Commons as to supplies of vaccine lymph for revaccination, the President is careful to explain again, as he explained last session, that the National Vaccine Establishment is simply concerned with the issue of lymph as *stock*, for starting fresh series of arm-to-arm vaccination, and that it is not proposed to do more than this when the establishment is enabled to supplement its supply of humanised lymph with animal lymph. In other words, if it has happened (as has been abundantly shown, and is now again being shown) that the regulations and suggestions of the National Vaccine Establishment in respect to the cultivation of lymph for revaccination have proved futile, so much the worse for the public; but it is of infinitely more importance in the Board's opinion to maintain the traditional practice of the National Vaccine Establishment intact, although it was established at a time when very different views as to the need for revaccination were held from those held now, than to disturb its even course by meeting a proved public want. Again, the decision of the House of Lords in the Hampstead Hospital case has thrown the Local Government Board into a state of perplexity, which proves how entirely it has been following a hand-to-mouth policy in regard to the metropolitan infectious disease hospitals. We have now the extraordinary spectacle of a great central body professing its present inability to deal with this hospital question in regard to small-pox until the Metropolitan Asylums Board has given some indication of what it is going to do; and, on the other hand, we have the latter Board equally professing helplessness until it is advised by the Local Government Board! This is a spectacle of the blind leading the blind, and both falling into the ditch with a vengeance. But not content with floundering in the sufficiently deep mire (as most persons would think) into which the Central Board had fallen prone, the President of that Board must seek to prepare other and deeper ditches for himself or his successors to fall into.

On the 19th inst. the President of the Local Government Board received a deputation of the inhabitants of the borough of Chelsea with regard to the Fulham Small-pox Hospital, headed by Mr. Firth, M.P. Nothing could be better than the mode in which Mr. Dodson referred to the Hampstead Hospital case. He said, as reported, "they [the Board] were now in a position of great legal difficulty by the decision which had been given in the Hampstead case, because it cast a doubt, at all events, upon the legality of maintaining these different hospitals. Some doubt had been expressed as to whether the intention was that these hospitals should be established for the benefit of London at large. He did not think the decision threw any doubt upon that point, as he understood it. These hospitals were provided at the expense of the whole of the ratepayers, and each and all of them for the benefit of the ratepayers at large. What the decision, so far as it went, had decided was this, that the Act did not give power to the managers of the Metropolitan Asylums to erect a hospital which was a nuisance to the neighbourhood, and which was convicted of being a nuisance." But what are we to think of the expression of opinion on hospital accommodation that followed, coming, as it did, from a responsible Minister of the Crown? "It has been suggested," said Mr. Dodson, "that there might be provision for the infectious sick in the different districts. He had been reminded that there were thirty-nine sanitary districts in the metropolis. If each of these districts contained a small-pox hospital he did not know whether the risk of the propagation of disease—whether they accepted the germ (!) or the contagion theory—would be less than by the larger hospitals. Many persons would be inclined to think that it would be much greater. Whether they had a large number of small hospitals or a few larger hospitals, the danger of spreading the disease by nurses, attendants, and visits of friends would be much about the same." In other words, the preposterous suggestion is made that the chances of incidental communication of the contagion of small-pox (setting the question of atmospheric diffusion aside for the present) to the members of a community in the immediate vicinity would probably be as great if the hospital were small as if it were large! This topsy-turvy application of the doctrine of chances surely needs no refutation, but suggested from such a source its mischievousness must be untold.

We are beginning to know something of the risks attending large accumulations of small-pox patients to the people living in the neighbourhood in which they are placed; we have a tolerably clear knowledge of the uncontrollable character of the contagion when the disease is retained in the houses of the poor—an uncontrollableness which, in conjunction with our knowledge of a like phenomenon with other infectious diseases, led to legislation as to hospital provision to be made by sanitary authorities. And now Mr. Dodson helps us to a suggestion that hospitals in regard to small-pox are equally harmful, whether of large capacity or not, and so condemns inferentially the legislation on the subject altogether, and lands us in the paradoxical position that every family ought to keep its own small-pox patients within its own circle! It seems difficult to believe that the President of the Local Government Board can have committed himself to statements such as we have quoted unless he has some evidence in hand concerning mischiefs from moderate-sized small-pox hospitals. Not a few of such hospitals were scattered about the metropolis in 1871 and 1872, but no account of them was ever given to the world, and certainly no suspicions ever got afloat as to their proving mischievous in the localities where they were situated. If the Local Government Board possesses an account of them, it is high time it was made public, and if the account confirms Mr. Dodson's suggestion, what possible defence can be made of the action of the Central Board in relation to the Metropolitan Asylums Board as regards their small-pox hospitals since the epidemic of 1871–72?

A correspondent drew attention in our columns last week to the casualties of medical officers in the late action in the Transvaal, where both the surgeons who accompanied the troops up the Majuba-hill lost their lives from wounds received in that action. Since the publication of this letter the relative *advantages* and *disadvantages* of the two positions, that of "combatant" and that of "non-combatant," have formed the subject of an official utterance by the Secretary of State for War in his place in Parliament. Mr. Childers observed: "I cannot undertake to lay down the broad proposition that non-combatant officers are to have all the advantages of combatant officers, unless the converse be also accepted—that is to say, that they are to have all the disadvantages." Paramount among these disadvantages we take to be the risk of casualty in action. The facts in relation to these matters are exceedingly interesting.

We have repeatedly pointed out that the term "non-combatant" as applied to army surgeons is a misnomer; their death-roll from all causes is shown by statistics to be 20 per cent. higher than that of the so-called combatant officers. No one will deny that a medical officer struck down while attending his men in cholera or yellow fever epidemics does sacrifice his life to the call of duty as much as the military officer who is slain on the battle-field. The two recent campaigns show that in addition to the risks of climate and disease to which all branches of the military service are necessarily exposed in warfare, our army surgeons are called in the discharge of their duty to be under fire, are often wounded, and often die. The Afghan or Boer bullet shows no discrimination in sparing a medical "non-combatant." Proof is hardly needed, but the casualties amongst medical officers in Afghanistan, Zululand, and the Transvaal, shown by the following list, are strikingly convincing of the soundness of the argument we advance:—

Killed or Died from Wounds, Climate, and Exposure.—Deputy Surgeon General J. H. Porter, Cabul; Surgeon-Major H. Kelsall, Khyber Pass; Surgeon-Major J. Wallace, Lundi Kotal; Surgeon-Major J. Wright, Attok; Surgeon Ambrose Kelly, massacred at Cabul; Surgeon Keith, Cabul; Surgeon-Major Bolton, Kandahar; Surgeon-Major A. R. Hall, Malta, *en route* from Kandahar; Surgeon-Major Peter Shepherd, massacred at Isandlana; Surgeon Brice, massacred at Isandlana; Civil Surgeon Glanville, massacred at Isandlana; Civil Surgeon Cobbin, massacred at Intombi; Surgeon-Major Cornish, Lang's Nek; Surgeon Landon, Lang's Nek.

Wounded in Action.—Deputy Surgeon-General Townsend, Kurram Valley; Surgeon Duncan, Peiwar Kotal; Surgeon Burroughs, Afghanistan; Surgeon-Major Preston, Maiwand; Surgeon Ward, Transvaal; Surgeon Longfield, R.N., Ekowe.

Nevertheless we think it a matter for regret that Mr. Findlater should have asked the Secretary of State for War whether "he would take into consideration the justice of extending to the Army Medical Department the privilege now enjoyed by all combatant officers of counting as full-pay service towards retirement any time on half-pay, not exceeding one year, when such half-pay had been necessitated by sickness incurred in and by the service; also such half-pay as results from reduction of the departments, not exceeding two years, as laid down in the Army Circulars, March 1st, 1880." It is little more than a year since the conditions of service of the army medical officers were revised, and a new Warrant was brought out introducing marked improvements in them. Among others, there was an extension, from six months to one year, of the period during which a medical officer may be retained on full-pay when disabled for duty by sickness contracted on service. The provisions of the Warrant gave general satisfaction to the department and the profession, and we think Mr. Findlater has been injudicious and ill-advised in attempting to reopen the subject. Mr. Childers was fully justified in adverting to the recent settlement of these questions as a ground for refusing again to take them up, and he fairly pointed out that medical officers cannot expect to have all the advantages enjoyed by combatant officers unless they are prepared at the same time to accept all the disadvantages. This argument, however, appears to involve the duty, on Mr. Childers' part, of seeing that medical officers are not unfairly deprived of any of those advantages common to both branches which have been acknowledged to be justly due to them. We recently pointed out that one of these privileges —a fair share in the distribution of rewards and honours—had been withheld. One of the points very clearly laid down by Lord Cranbrook's Committee, and accepted by the late Secretary of State for War, was that in such distribution "the Medical Department should be judged rather by the standard for combatants than for non-combatants," and we trust Mr. Childers will take such measures as he may deem most advisable to ensure this being carried into effect in spite of the opposition practically shown to it by the authorities at the Horse Guards.

We gladly welcome, and will try to cherish, the hope that a satisfactory system of management is, at length, being established at Guy's Hospital. The new regulations which lie before us do not, indeed, bear out all the bright promises with which the profession and the public have been entertained during the last few weeks, but possibly they mean more than they say. It is, however, so common an experience that these radiant harbingers of reform mean *less* than they say, that we must, at the risk of being judged hard to please, and even censoriously hypercritical, venture to point out a few dark specks on the halcyon prospect.

At the outset, while it is cheering to note that the Sisters are to be "appointed by the Taking-in Committee," it is not equally satisfactory to find that they "shall be selected from the register of applicants kept by the Matron." It is natural that applicants for the office of "Sister"—that either meaningless or mischievous title for a chief nurse—should address themselves to the Matron; but it is not, therefore, necessary that the "Lady Superior" or "Lady Superintendent"—who, we are glad to note, is henceforth to content herself with the more modest designation of Matron—should be entrusted with the construction of a "register" which is to be the passport to patronage. This may seem a small matter, but, looking to the recent history of the institution, it would have been better to avoid even the appearance of evil. Far more serious is the provision that the Sisters, when appointed, "shall be responsible to the Treasurer, Superintendent, and Matron for the efficient nursing and good order of the patients," &c. Considering that the whole of the recent trouble has been due to the persistent resolve, and endeavour, to subordinate the "nursing" to the views and will of the Treasurer and Matron, it is, at least, disquieting to find that the same authority is to be dominant. We attach no importance whatever to the fact that the Superintendent is to be one of the Triumvirate. The medical man holding that office is not, at Guy's, as shown by experience, necessarily the representative of the medical staff; but if he were, looking to the fact that "the Taking-in Committee" is to appoint the Sisters, and that this Committee meets every week, and is supposed to exercise some of the functions of a "House Committee," it is, we fear, significant that it has not been entrusted with a share of the authority now vested in the Treasurer, Superintendent, and Matron, with respect to what is essentially a prominent element of the medical work—that is, the nursing! Nor are we able to regard with entire confidence the specification of duties which the Sisters are required to fulfil. What, for example, is the meaning of the clause in Rule 4, which enjoins that "they shall endeavour to have the bed-cards filled up by the medical or surgical registrars either before or shortly after the patients have left the hospital"? Surely it is, or ought to be, the business of the resident medical officer to see that the medical and surgical registrars do their duty. Are these young men to be taught their profession or kept up to their work by the Sisters? The Superintendent furnishes the cards, and it is *his* function to see that they are duly filled up. There can scarcely be a just appreciation of the line which should be drawn between the duties of a nurse and those of a resident medical officer, when such a regulation as this can be either newly framed or retained. Again, Rule 10, which more explicitly defines the duties of the Sisters, directs that "they shall pay particular attention to the state and symptoms of the patients, especially if these be of an uncommon nature, that they may be able to report to the attending physician or surgeon, whom they shall *accompany* when visiting the patients." There is, of course, no objection to a nurse watching a case; it is obviously a part of her duty to do this, but the position she occupies would be more clearly and justly marked if she were directed to *attend* the physician or surgeon, instead of to "accompany" him round the ward. It might not be worth while to criticise this expression, but that further on in the same Rule we find the salutary but strangely worded intimation that "they [the Sisters] shall on no account give medicine to patients without the *concurrence* of the medical attendant;" and when in doubt as to her instructions, the Sister is to "apply at once to the House Physician or to the House-Surgeon for *advice*." The italics are ours. It may be simply a concession to the maudlin and false sentiment of the day in respect to "woman's place" and "women's rights," that the nurses in charge of wards are instructed in this more than equivocal phraseology, just as it is in deference to a spurious religious sentiment that they are called "Sisters;" but we think it is a mistake, and, for ourselves, we should certainly regard with distrust not less than dissatisfaction regulations thus drawn. The general impression conveyed is either disquieting or misleading. Again, what is the meaning of Rule 13, "They shall be at liberty to employ the patients to assist in the ward work, provided always such employment be *certified* by the medical attendants to be not inconsistent with their recovery"? Are the medical attendants at Guy's—who, as it is, have not time to keep, or dictate, the usual clinical records of their cases—to give a certificate to the Sister for each patient who may safely be employed to do a little dusting in the ward? The notion is grotesque. It is, however, part of a system which seeks to make the female nursing element an agency apart from, and only loosely related on equal terms, instead of being subordinated, to the medical treatment.

The new regulations for "nurses"—a lower order of beings in the hospital system—also challenge some criticism. These women, who are in fact the immediate attendants upon the patients, and therefore the direct agents of the medical staff, are to be "engaged and discharged by the Matron, with the concurrence of the Superintendent, and shall be under the immediate control of the Sister of the Ward to which they are appointed." The Taking-in Committee has a qualified jurisdiction—on appeal—in the matter of the change of nurses. They are not, as under the recent bad *régime*, to be removed capriciously from ward to ward. The "concurrence" of the medical officer is to come into play in this matter, and unless he actively *concurs*—in some way—there will be few changes. This is a distinct gain, and, so far as we can gather from the wording of the new regulations—waiving for the moment the jubilant construction which has been hastily put on them—it is the *only* concession which has a clear and sharp ring in it. Nurses, like Sisters, are to "*accompany* the medical officers in the course of their daily visits," and, when requested or required, they are to attend to their medical duties, and even to assist the surgeons or dressers. This is considerate, particularly when we bear in mind that the sole business of the hospital is to treat patients with a view to cure or relieve them, and that "nursing" *is* treatment. There are interesting as well as grave points for notice—for example, when Nurse-probationers essay to rise from that low rank to the dignity of full Nurses they must "undergo an examination," which is to be conducted "by the matron *and one or more of the medical staff*." Might it not be well that the Medical Council should be moved to send inspectors to these important examinations, conducted by "the matron and one or more of the medical officers"? In all seriousness, it is difficult to believe that the bad spirit has been exorcised at Guy's, and that "nursing" is no longer to be glorified as a craft in itself while a farce like this is perpetrated. The simple question is, or ought to be, whether the *servants* employed in the wards of a hospital to carry out the instructions of the medical staff have been docile and dexterous. The ceremony of an "examination" keeps up the absurd and injurious impression that there is more in *nursing* than cleanliness, kindness, and womanly tact. The idea that there is anything more ought, in the interests of humanity and common sense, to be sternly crushed out, with or without the "concurrence" of the medical faculty.

We have said that the new regulations at Guy's Hospital are welcome. It is something—perhaps much—gained that the authority of the Treasurer is not so conspicuously asserted as in recent but, let us hope, *past* times. That this authority is not suspended is clear from the provision that the "Sisters" are to be held responsible to the Treasurer as first and chief in a triumvirate, upon which the medical staff is not, as it ought to be, directly represented. We must wait to see how the work of reconstruction is carried out at this hospital before forming a final judgment on the new instructions, or attempting to form an estimate of the good which may have come out of the evil that awhile ago filled certain members of the medical faculty and the profession and the public with alarm. It is, perhaps, natural that the Governors should be unwilling to change their policy too openly and suddenly, though it is only manly to confess an error, and to mend it straightly when once it has been discovered and exposed. The proper course to have taken would have been to admit certain members of the Medical Faculty to the Board, instead of giving them seats as a Sub-Committee, and thereby to have recognised the medical element in the active management of a medical charity. The Founder of the hospital plainly intended that medical men should have seats on the Committee of Management; but the present administrators of the trust have, true to the spirit of modern progress, "shaken off the dead hand." We pause to see whether the living hand which has now undertaken the work of reform at Guy's will be loyal, firm, and dexterous. It is in no carping mood that we criticise the concessions which have been made, but we must remember that there is not less need of public caution in this matter than of personal consideration and courtesy.

◆

THE operation of nerve-stretching as a means of treating locomotor ataxy was introduced, it will be remembered, by Dr. LANGENBUCH, who recorded a startling improvement in a case so treated, the intense pains and considerable ataxy having almost entirely disappeared after the operation, and the diminished sensibility having returned to the normal. Symptoms of similar character and of marked degree persisted in the upper limbs, and, indeed, appeared to have become more intense. Hence it was decided, three months later, to stretch also the nerves of the arms. While the patient was under the influence of chloroform an epileptic fit occurred, and he died. The spinal cord from this important case was given for microscopical examination to Professor WESTPHAL, who has just published the results in the *Berlin. Klin. Wochenschrift*. The cord was seriously crushed at certain places, probably in the process of removal. Other parts, however, were in good condition for examination, especially the lumbar enlargement, the upper part of the cervical region, and small parts of the dorsal region. These parts showed nowhere the clear tracts which indicate the presence of sclerosis in hardened cords. Microscopical examination in glycerine showed no granule corpuscles nor the translucent appearance which indicates degeneration. After tinting, the posterior columns were found intact throughout, without a trace of sclerosis or of atrophy of the nerve-tubules. The periphery of the posterior columns, in which a slightly paler colour had been noted with the naked eye, tinted more deeply than the rest, and here the regular arrangement of the nerve-fibres was wanting, and the condition showed clearly that this appearance had only arisen from an injury during the removal of the cord. Sections from the dorsal region and the upper cervical region showed also a perfectly normal white substance, nowhere any trace of sclerosis or of atrophy. No abnormal changes were found in the grey substance, and the nerve-fibres of the anterior and posterior roots exhibited also no trace of atrophy.

It is certain from these facts that the case was not one of posterior sclerosis. Can we (WESTPHAL asks) from these facts draw the inference that in a certain stage of tabes the disease may exist as a neurosis without structural changes, and that the degeneration of the posterior columns represents a later and consecutive change which has nothing to do with the special symptoms, in accordance with the older view held by TROUSSEAU? This conclusion seems incompatible with the fact that in all cases examined hitherto, without a single exception, structural changes in the posterior columns have been found. Moreover, the case of Dr. LANGENBUCH does not, he urges, point to such a conclusion. The clinical history has only been very briefly recorded, but the facts as stated are altogether peculiar. The affection had been of very rapid development; although the symptoms were advanced, they had only existed for a few months, and the arms were considerably affected a few months later. The case thus resembles those of so-called "acute ataxy," such as occur spontaneously or after acute febrile diseases, and which have a course altogether different from that of ordinary tabes, often ending in complete recovery. The nature of these cases is unknown.

LANGENBUCH was inclined to regard his case as one of a primary affection of the peripheral nerves, but, unfortunately, the large nerve trunks could not be removed at the post-mortem examination. It is, however, noteworthy that at the operation the left sciatic was seen to be "reddish and somewhat swollen."

In publishing these facts, WESTPHAL does not desire to discountenance the operation in other cases in which the existence of a spinal lesion is undoubted, since, as he rightly points out, experience rather than theory must be our guide; but he strongly urges, and with reason, the great importance of a thorough and skilled examination of the nerve symptoms in all cases before the operation, that we may know whether the cases so treated are to be regarded as examples of true posterior sclerosis or not.

◆

THE evil to which "L. S. C." directs our attention to-day is becoming a very serious one both for the public and for medical practitioners. It may be characterised as the Private Dispensary System. On Feb. 5th "L.R.C.P. Edin." strikes a very kindly note of warning to young medical men, who are often victimised in connexion with this "so-called Provident Dispensary." It is important at the outset to draw a distinct line between the proper Provident Dispensary and the "so-called Provident Dispensary," or, as we have called it, the Private Dispensary System. The Provident Dispensary is an institution managed by a Committee of a public character, with which several medical men are connected, and to which the working classes subscribe, in sickness or in health, by a systematic weekly payment all the year round. The Private Dispensary, on the other hand, is rather a mysterious and dingy-looking affair. It is here to-day and in another street to-morrow. The gentleman to be seen on the premises is generally one whose name is not to be found in the Medical Register, and his appearance occasionally suggests that, however affluent the receipts, they do not go to his tailor. It is true that generally the name of a registered medical man is placed in large letters over this institution, or over these institutions, for one gentleman generally owns a group of them, and occasionally his carriage may be seen at the door of one of them, suggesting a grandeur in strange contrast with the humble style of the unqualified assistant who sees most of the patients and does most of the work. Well, the question is: What is the harm? Who is injured? What business have we or any others to assume the office of censor in regard to such experiments? The question is a very fair one, for we are strongly of opinion that no perfectly satisfactory means have yet been discovered of adjusting the supply of medical service to the poor on conditions of efficiency and dignity. We will frankly admit that neither the Provident Dispensary nor the Free Dispensary appears to us satisfactory. In the one the medical man seems to be paid, and is so only very inadequately, the patient perhaps thinking that he is paying him handsomely. In the Free Dispensary the medical man does the public's work of charity, and the poor are often degraded by it. But this is not the question just now. We are concerned with the evils of Private Dispensaries, and have to justify ourselves for speaking of them in terms of warning. We warn the public against them, for it has been repeatedly shown that they are worked on a large scale by unqualified assistants, and often very ignorant ones. This comes out in the letters of our correspondents, and occasionally at the inquests of coroners. Persons who are seriously ill will do much better to go to the private house of a neighbouring medical man than to a cheap or Private Dispensary, which is presumably worked by an assistant who probably knows no more than a neighbouring chemist. There have never been wanting good men in poor neighbourhoods who have adapted their fees to the means of their patients. Or if people do go to the Private Dispensary, we should advise them to ascertain whether the person they see is the principal, and whether he is a registered medical man. Another class has to be warned against the ways of some of those who deal in Private Dispensaries. Our correspondent of Feb. 5th, "L.R.C.P. Edin.," points out the snares that the "so-called Provident Dispensaries prove in the great majority of instances to young medical men who are tempted to eagerly purchase what on the surface appears a most profitable investment." It would be most wrong to think that all men who try to work Provident Dispensaries work them delusively, and sell them at a higher price than they are worth. We would fain believe that our correspondent may be wrong when he estimates that "the great majority" of those who sell Private Dispensaries are selling what is comparatively worthless. But nobody who does not shut his eyes can fail to see that a new trade has arisen in the profession which needs to be guarded against—viz., the sale of quickly extemporised and as quickly abandoned Dispensaries, as different as possible from the sale of a well-conducted and long-remembered private practice. We repeat the expression of our respect for men who for modest fees give their own advice to the poor. But we distinguish between them and those who only give their names to Dispensaries, send to the poor unqualified assistants, and after having created a Private Dispensary proceed to sell it.

Annotations.

"Ne quid nimis."

THE METROPOLITAN ASYLUMS BOARD.

AT the meeting of the Metropolitan Asylums Board, on the 20th instant, Dr. Brewer in the chair, a report was presented by the General Purposes Committee, prepared by the Board's solicitors, on the position of the Board in relation to the Hampstead Small-pox Hospital since the recent decision on that case in the House of Lords, and a deputation was received from the Sanitary Committee of the Hackney District Board of Works, headed by Mr. Gane and Dr. Tripe, to submit certain statements on the structural arrangements of the Homerton Small-pox Hospital. The statements, in form of memorial, as to Homerton were referred to the Homerton Hospital Committee. The report as to the Hampstead case, referred to Appeal No. 1 in the House of Lords, which was for a new trial, and which had been placed in suspense, and to Appeal No. 2, on the question of law, which had been heard before the House of Lords and had been decided against the Asylums Board. The report was accepted, and, after consideration, the following resolutions were passed:—"1. That the solicitors should be directed to proceed with Appeal No. 1—i.e., for a new trial,—the House of Lords to be asked to relieve the Board from the payment of a certain amount of the plaintiffs' costs, as ordered by the Court of Appeal as a condition of granting the appeal for a new trial. 2 (as a rider to the former resolution): That the managers desire to be now advised by the Local Government Board whether they are to receive any more small-pox patients into the hospitals, and what, if any, steps the Local Government Board propose to take with a view to give the managers authority to carry out their duties without further molestation and litigation." The first resolution was carried by a majority of 1 (the votes being 20 to 19), and the second unanimously. What the Asylums Board hope to gain by a new trial in the Hampstead case it is difficult for any but the legal mind to foresee. With regard to the second resolution, it may be said that in speaking to the Fulham deputation, on the 19th, Mr. Dodson stated that the Local Government Board would not come to any decision upon the course it should take in its present perplexity anent the metropolitan small-pox hospitals until the Metropolitan Asylums Board had decided upon *their* course. It now appears that the Asylums Board is waiting upon the Local Government Board to declare themselves.

NAVY MEDICAL DEPARTMENT.

IN bringing forward the Navy Estimates, Mr. Trevelyan adverted to the very unsatisfactory state of the Medical Department. Instead of having, as he conceived ought to be the case, four candidates for every vacancy, they have four vacancies for every candidate; and it is long since the supply of candidates has been equal to the demand. The supply of late years has come in large proportion from the Irish medical schools. "It was important in a national service that candidates should be drawn from all parts of the United Kingdom. They had, however, only 103 from the medical colleges of England, 128 from Scotland, and 251 from Ireland." We presume these numbers have been calculated from the officers actually in the service, for it would require the returns of very many bygone years to make up a total of 482 candidates. Mr. Trevelyan stated that it had been determined to adopt the report of the Committee on which the recent changes in the Army Medical Service had been based, and to add to the pay 7 per cent. to compensate the naval medical officers for the more disagreeable nature of their service. He added that there were other advantages which they would enjoy, and that he had no doubt the difficulty to which he had referred (of obtaining an adequate supply of candidates) would be removed. We are promised that an Order in Council embodying these improvements will be published in a few days. Until this is done we reserve all further remarks, except that we trust the new regulations may be of such a nature as to remove the existing objections to the service, and to make the Naval Medical Department a desirable career for well-educated gentlemen. Meanwhile we remark with satisfaction that we were the first to point out that, as regards pay, this principle had been evolved from the inquiries made by a committee that sat in 1866, and we trust that this Government will extend that principle more generally, taking other directions than that of pay only, as many improvements are required other than those so long established. It is a subject for regret that at the commencement of the present movement, when the age for retirement of the senior medical officers at sixty for sixty-five years of age was effected, a great error was committed in depreciating the value of their services to about seven per cent. below, instead of seven per cent. above, that at which those of the senior officers of the Army were computable, and soon after computed in a new Army Warrant; this inequality remains to the injury of the officers affected. This should be redressed in the forthcoming Warrant, as it shows that in small matters the Navy is too apt to be thrown in the shade of the Army. The medical schools of England and Scotland do not now yield so many candidates for the Navy as Ireland alone does, while Oxford, Cambridge, and the London Universities are not represented in the Naval Medical Service.

SUPPRESSION OF TYPHOID STATISTICS BY THE FRENCH GOVERNMENT.

THE French Government appears to have resorted to the feeble expedient of secrecy to cover sanitary imperfections which it is its duty to reform. Dr. Galliott, of the French Marines, had written a remarkable report on the prevalence of typhoid fever in the Toulon barracks, and had received a gold medal from the Ministry of Marine in recognition of his services. Anxious to study the fruits of a large experience, a correspondent applied to Dr. Galliott for a copy of his report, and was not a little surprised to hear that he had been expressly forbidden to show it to anyone. The gold medal was allowed to be shown; but the report which had won this reward was for ever consigned to silence and oblivion of a ministerial pigeon-hole. Some facts in reference to the matter, however, have been ascertained. The barracks of Mourillon are unfavourably situated, and were till recently occupied by about 2000 marines. In front of the barracks there is a large main sewer, which is not water-tight. Hence the organic matter and sewage from the village of Mourillon accumulate in front of the barracks to a depth sometimes of a yard and a half. This can only be cleared away by rain; but it rarely rains on these coasts unless there is an east wind; and, as the mouth of the sewer which communicates with the sea faces the east, the waves beat up against it and check the exit of the sewage. The decomposition of organic matter in the sewer is therefore facilitated by the admixture of water, and the leakage is increased. Hence arise continuous outbreaks of typhoid fever in the neighbouring barracks, these outbreaks corresponding very accurately with high temperature, easterly winds blocking the mouth of the sewer and rain increasing the amount of sewage and accelerating its fermentation. The number of cases that have occurred is appalling. We cannot of course give the numbers, as communication of the official returns was not allowed; but from several indirect sources, it is pretty clearly shown that there were about a thousand cases of illness during the course of twelve months, and that half of this number were fully developed cases of typhoid fever, while a large proportion of the remaining patients also showed symptoms of a suspicious, if not of so conclusive a character. The majority of cases occurred among the volunteers for one year's service, for these men are young, eighteen to twenty years old, and therefore most susceptible. Indeed, it seems that a young recruit, if quartered in these barracks, would have little or no chance of escape, from at least a slight, if not a fatal, attack of enteric fever. That the report in which these facts are set forth is not published is much to be regretted, as it gives remarkable evidence derived from many hundreds of cases of the extreme susceptibility of certain classes and the total exemption of others. Youths coming from countries and districts free from typhoid fever almost invariably contract the disease when quartered in these barracks; while the natives of Toulon, and others living in similarly contaminated centres, have been so thoroughly inoculated with the poison that the specially unfavourable position of the barracks does not affect them. It is satisfactory to learn that after many years of illness and a scandalous and wasteful loss of many hundred lives, the quartering of young recruits at the Mourillon barracks has at last been forbidden. These are now sent either on board ships, or in the outlying forts. Only a small number of older soldiers, numbering 1200 in all, and who have passed the most susceptible age, are allowed to inhabit these fatal barracks, and the result has been that no more cases of typhoid fever have occurred.

THE PATHOLOGY OF ATHEROMA.

THE theory of the origin of atheroma, to which Virchow has given currency, regards it as of inflammatory origin, and has been conveyed into modern pathology by the help of the name "endarteritis deformans." This designation, although not unassailable, has been widely accepted on account of the apt expression which it gives to the conspicuous characters of the morbid change. The same theory of initial inflammation has been, in effect, adopted by Lancereaux, while Cornil and Ranvier do not admit any other element in the morbid process than simple degeneration.

The latter view is regarded as the more probable by the writer of a recent memoir in the Paris *Revue de Médecine*, M. Hippolyte Martin, who has endeavoured to ascertain the pathological origin of the degeneration, and believes that he has found it in a lesion of the nutritive arteries of the walls of the vessels, to which the visible degeneration is simply secondary. In the early stage of the affection the cells of the connective tissue of the vessels may be found notably increased in number, and the middle and internal coats are increased in thickness; these changes cannot be regarded as the result of any irritation by the globules of fat which may be found sparsely scattered through the wall. If the minute vessels which ramify in the external coat before penetrating the middle layer are examined, they are found to be healthy, with the exception of those which correspond to the spot of atheroma. Here, however, the nutritive artery of the degenerated region presents a striking proliferative endarteritis, which, in the case of extreme degeneration of the atheromatous patch, amounts to almost complete obliteration of the minute vessel, so that very little blood can circulate through it. This lesion is never absent, although considerable care may be necessary to find it. The change is only found in the vessel going to the diseased spot; other arteries, although closely adjacent, may be perfectly healthy. But it may be held that in the old, in whom generalised arterial disease is common, the affection of the arteries, and of their nutritive vessels, may be due to the same cause, and do not stand in any causal relation. In contravention of this objection, M. Martin describes the case of a lad, nine years of age, who died of diphtheria. At the autopsy two atheromatous spots were found in the commencement of the aorta, above the sigmoid valves. They were well marked, about a square centimetre in extent. All the other vessels were healthy. Sections at the position of the atheromatous patches showed, in the middle of healthy tissue of the outer, and even of the middle coat, a perfect example of endarteritis of the nutritive vessels, one of which was almost obliterated. Moreover, it was evident from the histological characters of the two that the affection of the nutritive artery was of older date than that of the inner coat of the aorta.

This lesion in the vasa vasorum appears to commence in their inner coat, the nutritive supply to which is always the most difficult, but at a later stage the middle coat is also affected, and its muscular fibres may be observed to undergo a fatty degeneration. This alteration is regarded as inflammatory in nature, the result of some, at present unknown, cause. The facts Martin has ascertained are of much interest and importance, but they only put the origin of the disease farther back, and farther into the region of pathological mystery. It is conceivable that mechanical strain and other causes may determine the occurrence of a degenerative inflammation beginning in the wall of the strained vessel, but the cause of the affection of the vasa vasorum is entirely unknown. The change in the larger artery may be due to the disease of the minute vessels, but what is to explain the latter lesion? And if we admit it to be a primary endarteritis, may not the disease of the wall of the larger vessel be in many instances of the same nature?

PHYSIOLOGICAL PROPERTIES OF THALICTRIN.

M. DOASSANS in an inaugural thesis published in Paris, and abstracted in the *Revue Scientifique*, has given some very interesting particulars in regard to the action of the essential principle of a plant rarely found in the Pyrenees, named the Thalictrum macrocarpum, belonging to the Ranunculaceæ. The root of this plant contains two substances, which have been isolated. One is an alkaloid, to which M. Doassans has given the name of thalictrin, and which proves to be, although as yet he has only been able to obtain it in too small quantities to permit its composition to be determined, a crystallisable substance, capable of combining with acids to form crystallisable salts. The other substance is a yellow colouring matter, which apparently confers the yellow tint characteristic of the fresh section of the root. On treatment of the root with successive portions of alcohol, and with water acidulated with hydrochloric acid, this yellow substance can be obtained in a state of purity, and has been christened *macrocarpin*. Macrocarpin is neither an alkaloid nor a glycoside, but a substance which chemically resembles berberin, from which, however, it differs in some particulars; it has no therapeutic action.

Thalictrin, on the contrary, has well-defined and powerful physiological properties. If a certain quantity of the aqueous extract be subcutaneously injected into a frog a local action is immediately observed, the contractile power of the muscles becoming impaired. After a short interval the muscles contract, and the limb which has been injected becomes hard and rigid. Injected beneath the skin of a dog, it causes sharp pain, and sometimes, owing to its irritating local action, the formation of an abscess. A dose of from two to three centigrammes proves fatal to a frog in the course of three or four hours, and about ten times the quantity of the salts of thalictrin is required to produce the same effect. A dog is killed with quantities varying from two to four grammes when subcutaneously injected, but its toxic influence is much less when swallowed. The principal symptoms observed are general weakening of all the functions governed by the nervous system. The arterial pressure is lowered to an extreme degree, which is dependent, not on dilatation of the capillaries, but upon great diminution of the force of the cardiac impulses. The pulse becomes more frequent. The respiratory acts are also increased in number, yet no true asphyxia is perceptible, for the arterial blood remains red, and the relative amount of oxygen it contains is augmented rather than diminished. Indisposition to perform voluntary movements is observed, but the general sensibility is not generally much impaired. The nerves preserve their action on the muscles to the end of life, and the pneumogastrics continue to act upon the heart. The muscles preserve their irritability. Death appears to follow as the result of progressive weakness of the heart, respiration continuing frequently some time after the heart has ceased to beat, which shows that the centres presiding over the respiratory movements are not so profoundly affected as those which govern the cardiac movements.

MEDICAL OFFICERS (IRELAND) SUPERANNUATION.

A RETURN has been issued by the House of Commons consequent on a motion by Mr. Meldon, M.P., of all medical officers of workhouses and dispensaries in Ireland who since the passing of the Medical Officers' Superannuation Act have resigned their appointments and applied to their Boards of Guardians for superannuation; further, the causes for such resignations, their length of service as poor-law medical officers, and the result of their application to the Guardians. The return shows that since the passing of the Act in question 189 medical officers applied for a retiring allowance, and of these twelve were refused, the reasons assigned for the latter proceeding generally being that the Guardians were opposed to granting retiring allowances to any officer of the union, and sometimes because the applicant held other public appointments. Forty-seven medical officers, or one-fourth of the applicants, obtained the full retiring allowance of two-thirds of their salaries. In one instance, that of Dungannon Union, where the medical officer of the workhouse did not apply for superannuation, the Guardians of their own accord proposed and agreed that two-thirds of the salary should be granted to Dr. Ambrose Hunt.

PARASITIC EPILEPSY IN THE DOG.

A REMARKABLE form of disease in the dog was described by M. P. Mégnin at the meeting of the Société de Biologie on Feb. 5th. A number of dogs belonging to a gentleman near Havre, although of different races and coming from different sources, were affected with a disease which caused epileptiform convulsions and ultimately death, after several months. These cases of disease recurred, with similar characters, during several years, and all the dogs which he bought to replace those that died ultimately became affected by the disease. The yard was several times thoroughly disinfected, the walls limewashed, and yet the epidemic persisted without modification. A terrier thus affected was sent to M. Mégnin, who watched the dog carefully for eight days and observed the epileptiform attacks, and also the frenzied blows which it constantly gave to its ears. Examining the interior of these organs he found the external auditory meatus lined with a thick layer of cerumen, dotted with minute almost imperceptible white points, which were discovered, on microscopical examination, to be acari of the species described under the name of Chorioptes ecaudatus. This species of acarus was first described by M. Mégnin as met with only in the auditory canal of dogs, cats, and ferrets, and he was aware that it was capable of causing attacks of frenzy, but had not observed that these might have an epileptiform character. The discovery of this parasite explains the remarkable contagious character of the epileptiform affection. The proof that the symptoms were really due to its presence was afforded by the fact that the repeated injection into the meatus of a solution of 5 per cent. of sulphide of potassium completely arrested the fits. M. Mégnin also showed, in confirmation of his conclusions, the ears of a rabbit which had died of an affection altogether similar to those which he had described. In the meatus was found another acarus, the Psoroptus longirostris, a species common to the rabbit and the horse, and which also causes in these animals a form of itch. As another illustration of the remarkable lesions caused by these parasites the foot of a cock was exhibited enlarged to four times its normal size by tubercular nodules, composed exclusively of stratified epidermic products. Under the deepest layers, in immediate contact with the corium, were myriads of the females of Sarcoptes mutans, engaged in depositing their ova. These acari do not cause furrows, and are not transmissible to the horse, or to the other mammalia, as has been asserted.

INTRA-PERITONEAL TRANSFUSION.

To obviate many of the difficulties and dangers of intravenous transfusion Ponfick has introduced a method of injecting defibrinated blood into the peritoneal sac, and has availed himself of the rapid absorption occurring from serous surfaces. His example has been followed by others, and Kaczorowski has recently published his results in the *Deutsche Med. Wochenschr.* He employed the method first in a case of puerperal septicæmia, and then in five other cases of anæmia and extreme exhaustion. He injected from 250 to 500 centimetres, and in one case repeated the larger quantity. In one case only was there no substantial result. The local reaction of the puncture, which he recommends should be done under antiseptic precautions, he found to be very slight, and even the entrance of pure air to be harmless. He recommends that intra-peritoneal transfusion should be practised in cases of protracted fever where there is threatened paralysis of the heart, and also in chronic anæmia without fever.

On Tuesday, the 22nd inst., a large meeting of the Central Committee for the closing of Fulham Small-pox Hospital met at Albert-gate, Mr. Firth, M.P., in the chair, to consider what should now be done, as the managers of the Asylums Board intend to re-open the whole matter of the Hampstead Hospital case by the prosecution of the first appeal—viz., whether the hospital is itself a nuisance, or by its administration has become a nuisance to the neighbourhood. The Chairman and other speakers strongly condemned the new action of the Asylums Board, stating that they were now commencing legal proceedings for which again the ratepayers would have to pay without any chance of a successful result. A resolution was unanimously passed that the Central Committee should adjourn to that day fortnight, for the purpose of obtaining subscriptions to the guarantee fund to the amount of something like £5000, and that immediate legal proceedings should be taken to move for an injunction against the Fulham Small-pox Hospital as a dangerous nuisance, and to demand the closing of its wards.

We have received the prospectus of a new quarterly journal, *L'Encéphale*, to be published in Paris under the direction of Professor Ball and Dr. Luys. It will be devoted to mental and nervous disease. The first number was to appear on the 24th inst.

A northern lay contemporary directs attention to the inferior position held by the Faculty of Medicine in the University of Aberdeen in the matter of bursaries and scholarships as compared with that enjoyed by the Faculties of Arts and Divinity respectively. Thus, connected with the Arts Faculty there are 258 bursaries, of the aggregate annual value of about £4423; and eight scholarships, value £695. In the Divinity Faculty there are 38 bursaries and two scholarships, the former worth £823, the latter £35. Last and least, attached to the Faculty of Medicine there are but 10 bursaries, of the aggregate value of £173, whilst a single scholarship of £20 is the only prize of this description to which a medical tyro can aspire.

The movement for the establishment of a veterinary college in Dublin has of late been retarded, but the matter is at present engaging the attention of the Lord-Lieutenant; and it is stated that Dr. Lyons, M.P. for Dublin, has formulated a scheme which, if adopted, will meet the requirements of those who signed the memorial to his Excellency last December. What the memorialists desire is a college perfectly independent of the London institution, and which shall be not only a teaching, but also a licensing body.

Mr. Stansfeld has lately addressed a meeting at Croydon in support of the scheme for enabling the working classes of the metropolis to obtain, on provident principles, medical aid for themselves and their families. We have frequently called attention to the strong and the weak points of this movement, and need not here repeat our comments. Resolutions in favour of the proposed enterprise being tried in Croydon were passed.

A committee appointed by the Illinois State Health Board to investigate the condition of medical education in the State has recommended: (1) a strict preliminary education; (2) more clinical study; (3) three full years of study, one half of each year at least to be spent in a medical college; (4) a more rigid regard to the moral character of the applicants for admission to the profession.

In accordance with the report made by the special examiners, Professors Huxley, Michael Foster, and Thistleton Dyer, no election has been made to the Biological Fellowship offered by University College, Oxford. Another examination will, therefore, be held in the same subject, probably not earlier than the end of the present year.

An executive committee has been appointed, with the object of raising a testimonial to Professor Bain to commemorate his long connexion with the University of Aberdeen. The form of the testimonial is to be a portrait of the Professor, to be placed in the University, and the establishment of an annual gold medal as a prize in Philosophy.

The Members of the Irish Graduates' Association celebrated St. Patrick's day in London at the Holborn Restaurant under the presidency of Dr. G. E. Paget, D.C.L., F.R.S. Many of the leading physicians and surgeons of London and others were present at the festival.

An ardent supporter of cremation, M. Alfred Petit d'Ormoy, has recently died in France. Foreseeing that difficulties would be thrown in the way of cremation by the authorities, he directed that his body should be conveyed to Milan for that purpose.

THE managers of the Royal Infirmary, Edinburgh, have unanimously resolved to accept the offer of £24,500 made by the Town Council for the centre and western blocks of the old infirmary to be used as a fever hospital for the city.

THE veterinary school of Lyons has been temporarily closed in consequence of the riotous conduct of the students, who had organised an opposition to Professor Chaveau on account of his supposed clericalism.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Bournemouth.—Mr. Philip W. G. Nunn reports for this watering-place during 1880, in an estimated population of 13,000, a death-rate of twenty per 1000, and a birth-rate of thirty-three. The health-history of the year had been satisfactory, and characterised by the small amount of infectious disease in the place. It is gratifying to learn, in the interest of visitors, that considerable attention has been given to the sanitary condition of the hotels, and that the majority of them have had their drainage arrangements overhauled and placed in a condition which would satisfy the requirements of the model by-laws as to buildings issued by the Local Government Board. Still we are surprised to find that the sanitary administrative arrangements are still so imperfect that the system of tipping ash-refuse (often very offensive) in several parts of the district continues, and that large fixed ashpits are permitted. Mr. Nunn directs attention to the clearances of fir trees in and about Bournemouth, which has been going on for several years, without apparently any systematic attempts to supply the deficiency by replanting. He looks upon these trees as one of the greatest attractions of the place, also as playing a part in determining its celebrity as a health-resort.

Pontypool.—According to Mr. J. B. Mason the death-rate of this urban district, the population of which he estimates at 5100, was in 1880 15·8 per 1000 inhabitants. The health-history of the district during that year presented nothing for special note; but Mr. Mason records a parasitic disease, which he believes he has discovered in connexion with fluke in sheep, and which deserves a more detailed description than he devotes to it in his report, but which we give in his own words:—"I have condemned large quantities of mutton; in one case eighteen carcases, all very much in the same condition, owing to fluke in the liver. In most cases the meat appeared to the naked eye to be healthy and wholesome; but examination with high powers of the microscope revealed a wavy segmented parasite, occupying the sheath of the muscular fibre, leaving behind it a trail of minute eggs. After a deal of investigation I have associated this parasite with fluke in the liver. I believe meat or mutton so infested to be totally unfit for the food of man, and that this parasite may, in suitable cases, produce disease in man. I have had occasion to show this parasite to several medical officers of health, who agree with me entirely in its association with fluke."

Hitchin.—Mr. William Jenner, in his report for 1880, with reference to a sharp outbreak of scarlet fever, which appears to have been the chief disease event of the year, first takes his sanitary authority to task for not having provided an infectious disease hospital for the district. The want of a hospital crippled the efforts of the medical officer of health in endeavouring to stay the extension of the malady, and he writes very positively of the great use it would have been. The death-rate of the year was 22·4 per 1000 inhabitants, and the birth-rate 34·0 per 1000. Hitchin obtained the benefit of a constant water-supply in the course of 1880, but the distribution of the supply throughout the town is not yet quite completed. The drainage of the town was also materially improved.

Montrose.—Dr. S. Lawrence, in his report for this borough in 1880, estimates the population at 15,890 and returns a death-rate of 22·4 per 1000 inhabitants. He gives a pleasing picture of the advances which have been made in the sanitary condition of the borough in recent years. "Instead of a stinted there is now an abundant supply of excellent water, which, besides subserving domestic purposes, has permitted a long desiderated drainage system for the borough to become an accomplished fact; the prevention and removal of all nuisances is now more than ever an object of vigilant attention; facilities and attractive inducements to out-door recreations and exercises have recently been multiplied; in various quarters of the town antiquated, ill-constructed tenements have been removed, opening out freer space for light and air; and last, though not least, through the enterprise of intelligent and energetic citizens, a class of dwelling-houses has gradually sprung up vastly superior to those they are meant to replace or to supersede in all that pertains to sanitary conditions and arrangements." It remains now for the individual members of the community to give attention to the behests of personal hygiene. The local authority has done and is doing its duty; let the community personally do theirs, and Montrose may look forward to an even higher condition of health than it now enjoys.

Stroud (*Urban*).—Mr. Partridge estimates the population of this district in 1880 at 7608, and gives the death-rate for the year at 14·8 per 1000 inhabitants, the birth-rate at 36·1. The health history of the year was uneventful, but here is an illustration of small-pox diffusion. A tramp from Portsmouth enters the town, and sickens from small-pox in a lodging-house. He is removed, presumably for purposes of isolation, into an empty cottage near at hand; a man, the father of a family, is suffered to visit the invalid, in order to gratify his curiosity. This man "catches" the malady, and while he is ill a child of his, six weeks old, and who had been vaccinated only six days, is placed in the same bed with him. The child suffers from confluent small-pox and dies.

Dorking and Reigate.—Mr. E. L. Jacob's reports for these two districts show that no very special event characterised their health-history in 1880. *Dorking* (estimated population 16,350) had a birth-rate of 28·5 per 1000 inhabitants, and a death-rate of 13·4, and *Reigate* (estimated population 12,400) had a birth-rate of 34·0, and a death-rate of 16·5. An outbreak of diphtheria and accompanying throat-illness in the Reigate district, attacking twenty-five persons (twenty-two being children) and killing three, affords matter for more detailed comment in the report on the district. Milk infection might have played some part in the diffusion of the disease in two houses, the occupiers of which were cowmen, who continued their duties about the cows, including the milking, while the disease was in their families. The employer of one of these cowmen, a registered cowkeeper, was found to be unaware that diphtheria was one of the dangerous infectious diseases to which the prohibition of the Dairies and Cowsheds Order of the Privy Council applies, and Mr. Jacob conceived the notion that it would be well if the magistrates would take steps to make registered cowkeepers and dairymen of the district more fully acquainted with their duties under this Order of Council. But the magistrates, on the Sanitary Committee suggesting this view, took the simpler method of summoning the cowkeeper before them, and fining him £5 and costs.

Surbiton.—The death-rate of this urban district in 1880 is stated by Dr. Owen Coleman at 14·3 per 1000 inhabitants. The chief interest of Dr. Coleman's annual report rests in the brief account he gives of two outbreaks of diphtheria which occurred during the year, both of which were attributed to the dissemination of the contagion of the disease through milk, and both of which attracted attention outside the district at the time of their occurrence. Dr. Coleman is anxious to clear the sewerage of Surbiton of the imputation (made by some residents at the time) of having played a part in the outbreak of diphtheria, but he is evidently somewhat doubtful of his case, for he writes of the sewers only "as on the whole" good, and that "there is admittedly need for further ventilation of them"—very qualified approval, indeed, it must be said.

Chailey (*Rural*).—Mr. Richard Graveley reports a death-rate for this district, during 1880, of fourteen per 1000 of the estimated population. He has some thoughtful observations on the sort of houses in which so many of our poorer population live in rural districts, not so much "with a hope," he writes, "of remedying existing evils, but with a view of preventing others arising."

Okehampton (*Rural*), *Devon.*—Mr. Linnington Ash, although he has only held office a few months, in succession to Mr. Wynter Blyth, has prepared a report for this district for the year 1880. He returns a birth-rate of 25·4 per 1000 of the population, and a death-rate of 16·0. Mr. Ash sketches for the information of his authority the course he proposes to take in the execution of his duties, and we may anticipate that his next annual report, by which time he will have become familiar with his district, will contain much matter of interest.

Bury St. Edmunds.—Mr. Winter Clarke reports for this ancient borough, in 1880, a birth-rate of 32·0 per 1000 of the population, and a death-rate of 21·7. He states that a great improvement has been effected during the year by the adoption of a plan of compulsory, regular, and systematic removal of house refuse, through the operation of which the overflowing ashbins, and disgraceful accumulations of the past, have vanished.

Helmsley, Rural. — Dr. Bruce Low reports for the Helmsley division of the rural district a death-rate of 19·1 per 1000 inhabitants, and a birth-rate of 31·7. He has some instructive observations upon the nursing of illegitimate children, and expresses regret that the Infant Life Protection Act does not bring every single nurse-child under observation. The district seems to be woefully behind hand in regard to excrement removal and privy accommodation.

INFECTIOUS DISEASES ON BOARD EMIGRANT SHIPS IN THE THAMES.

The Port Sanitary Authority of the Thames have issued a series of instructions for the guidance of the masters of emigrant ships in the Thames in case of infectious sickness appearing on board their vessels. The instructions give clear directions as to the diseases included under the term infectious, and the course to be pursued to remove them to hospital from the ship according as the vessel lies above or below Woolwich. They must prove eminently useful to the masters of these vessels in the difficult circumstances they are sometimes placed in by the appearance of an infectious disease among a number of persons about to put to sea, or who have been brought temporarily into the port.

WORKHOUSE MILK.

Two cases are reported, both the subject of judicial inquiry, of attempts to palm upon workhouse authorities diluted milk. In the one case, at the Toxteth Workhouse, no less than sixty-four parts of water had been added to the skimmed milk, and thirty-three parts to the new milk. A fine of £10 with costs was inflicted upon the dealer. In the other case, at the Salford Workhouse, 22 per cent. of water had been added. In this case a fine of 40*s.* with costs was imposed upon the dealer.

The Jarrow journals report a somewhat curious case heard in the Jarrow Police Court a few days ago. A medical practitioner in the borough was summoned before the magistrates for an infraction of the Local Improvement Act. He had notified to the sanitary authority a case of "infectious disease," and the authority appear to have contended that according to the Act he ought to have specified the nature of the disease as "small-pox, cholera, or fever." The answer to this seems to have been that the notifier had satisfied himself of the infectious character of the disease before he had ascertained its precise nature, and that he had thought he best met the object of the Act by giving immediate notice of this, and not in delaying until he could designate its precise character. On the other hand, the authority maintained that it was his duty to wait until he knew the disease he was dealing with, and, in effect, that it was of more importance to meet the verbal requirements of the Act than the object for which the verbal construction was intended. The medical officer of health was put into the witness-box to say that he had visited the case after he had received the notice, and that, in his opinion, it was one of typhus. It is not stated how this evidence was supposed to affect the notifier's statement that he had not recognised the particular nature of the disease when he notified its occurrence. The Bench dismissed the summons, stating that there was not evidence to show that it was possible that the notifier could define the disease as being small-pox, cholera, or fever, and the notification was therefore the best that could be given under the circumstances. The case seems to have been very ill-advised, and indicates that the Jarrow Act, as regards notification of infectious diseases, wants amending.

A deputation, headed by Mr. Stavely Hill, Q.C., M.P., had an interview with the President of the Local Government Board, on Tuesday, to advocate an amendment of the Public Health Act, admitting of qualified inspectors being appointed (by local authorities we presume) to guarantee by frequent inspection that the sanitary arrangements of every building are constructed and maintained in proper order. Legislation as to construction of buildings will have to be put in a very different position from that which it maintains at present before this detail of administration can be usefully considered, and it is to be regretted that the deputation did not first deal with the general subject. Moreover, it appeared to have chiefly in view good class houses.

A deputation has had an interview with the President of the Local Government Board to urge upon him the desirability of provision being made in London for the isolation of patients from scarlet fever who had reached the convalescent stage. The President intimated that the time for the consideration of such a question was exceedingly ill-chosen, on account of the difficulty in which the Board was plunged by the recent decision of the House of Lords in the Hampstead Hospital case, but he apprehended that sanitary authorities might make such provision if they so willed. Sir Rutherford Alcock, Dr. A. P. Stewart, and others were among the deputation.

Dr. MacCabe, Local Government Board Inspector, in a recent inspection of the North Dublin Union Workhouse, states that it is not adequate to the requirements of the Union. The real accommodation, after setting apart a proper proportion of day-rooms, will provide beds for 2079 inmates; but during the six months ending December 31st, the average number daily resident has been 2210.

The Town Council of Southport have under serious consideration the system of sewerage existing in the town. When first established the influence upon the health of the inhabitants was very marked, the amount of sickness falling very considerably. But it is defective in several respects, and it has become desirable that a skilled engineer should be consulted upon the system generally.

The Manchester Corporation have applied to the Local Government Board for a further loan of £100,000 to carry out various improvements in the city, and in connexion with privy accommodation. Mr. C. N. Dalton, barrister-at-law, one of the inspectors of the Board, held an inquiry in the town-hall, Manchester, concerning this application a few days ago.

A Bill has been introduced into Parliament by Mr. Walter James and Mr. Bryce to amend the Metropolitan Spaces Act (1877), by giving power to trustees and others to transfer certain open spaces and disused burial-grounds to the local authorities, for public use as open spaces, and providing for the expenses of such transference and the maintenance of the grounds for public use.

The Withington Local Board contemplates taking action against the Rusholme Local Board under the Rivers Pollution Prevention Act for polluting certain streams running through their district.

The Lord Advocate and Home Secretary have brought a Bill into Parliament toen able parochial boards in Scotland, with the consent of the Board of Supervision, to grant superannuation allowances to their officers.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

Mortality in the large English towns showed a marked decline last week, and was lower than it had been in any week since the middle of December last. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 5576 births and 3001 deaths were registered last week. The births exceeded by 390, while the deaths were 256 below, the average weekly numbers during 1880. The deaths showed a decline of 351 from the number returned in the previous week, and were equal to an annual rate of 20·6 per 1000, against 23·0 in each of the two preceding weeks. The lowest death-rates in the twenty towns last week were 15·9 in Brighton, 16·4 in Hull, 16·5 in Plymouth, and 17·3 in Birmingham. The rates in the other towns ranged upwards to 22·2 in Oldham, 23·8 in Manchester, 25·4 in Liverpool, and 26·5 in Wolverhampton. During the first eleven weeks of the current quarter the death-rate in the twenty towns averaged 24·2 per 1000, against 25·6, the average rate in the corresponding periods of the five years 1876–80.

The deaths referred to the principal zymotic diseases in the twenty towns, which had been 290, 296, and 311 in the three previous weeks, declined to 287 last week, the lowest weekly number in recent years. These 287 deaths included 66 from whooping-cough, 56 from measles, 46 from scarlet fever, 44 from small-pox, and 41 from fever, principally enteric. The annual death-rate from these principal zymotic diseases averaged only 2·0 per 1000 in the twenty towns, and ranged from 0·0 and 0·3 in Plymouth and Hull, to 2·5 and 3·1 in Liverpool and Newcastle-upon-Tyne. Scarlet fever showed the largest proportional fatality in Leicester, Portsmouth, and Newcastle-upon-Tyne; and whooping-cough in Bradford and Liverpool. Nine of the 11 deaths from diphtheria in the twenty towns occurred in London. The death-rate from fever (principally enteric) showed an increase upon the low rates in recent weeks, and was highest in Leicester, Newcastle-upon-Tyne, and Manchester. Small-pox caused 46 more deaths in London and its outer ring of suburban districts, and one in Liverpool (of a coloured seaman recently landed from New York), while no fatal case was recorded in any of the eighteen other provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had steadily increased in the twenty preceding weeks from 77 to 792, further rose last week to 853, which is a higher number than has been under treatment in these hospitals at any time since April, 1878. The new cases of small-pox admitted to these hospitals, which had been 195 and 186 in the two previous weeks, rose to 265 last week, considerably exceeding the number in any recent week.

The deaths referred to diseases of the respiratory organs in London were 345 last week, and were 109 below the corrected average number in the corresponding week of the last ten years; 217 resulted from bronchitis, and 77 from pneumonia. The annual death-rate from lung diseases, exclusive of phthisis, was equal to 4·9 per 1000 in London last week; while the rate from the same diseases in Liverpool was 5·8.

The causes of 76, or 2·5 per cent., of the deaths in the twenty towns last week were not certified, either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths did not exceed 1·8 per cent. in London, while it averaged 3·2 per cent. in the nineteen provincial towns. No uncertified causes of deaths were registered last week in Bristol, Leicester, or Sunderland; while their proportion was largest in Oldham, Leeds, and Sheffield.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, the annual death-rate averaged 23·1 per 1000 last week, against 22·9 and 23·4 in the two preceding weeks; this rate was 2·5 above the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 14·7 and 15·9 in Leith and Greenock, to 25·3 and 33·9 in Glasgow and Paisley. The deaths referred to the principal zymotic diseases in the eight towns, which were 83 and 82 in the two previous weeks, rose to 97 last week; they included 31 from whooping-cough, 17 from diarrhœa, 15 from diphtheria, 13 from scarlet fever, 12 from "fever," 9 from measles, and not one from small-pox. The annual death-rate from these zymotic diseases was equal to 3·8 per 1000; this rate ranged from 3·0 and 3·3 in Aberdeen and Dundee, to 4·5 and 5·3 in Edinburgh and Paisley. The 31 fatal cases of whooping-cough included 17 in Glasgow, 6 in Edinburgh, and 5 in Dundee. The 15 deaths referred to diphtheria exceeded by 2 those in the previous week. Of the 13 deaths from scarlet fever, 5 occurred in Edinburgh and 4 in Glasgow. The deaths referred to "fever," which had been 6 and 10 in the two previous weeks, further rose to 12 last week, of which 6 occurred in Glasgow and 2 in Edinburgh; the annual death-rate from "fever" in the Scotch towns was last week nearly twice as high as the average rate from the same cause in the twenty English towns. Eight of the nine deaths from measles occurred in Glasgow. The deaths referred to acute diseases of the lungs, which were 179 and 168 in the two preceding weeks, further declined to 164 last week.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, although still excessive, showed a further decline last week. The annual death-rate in the city, which had slowly but steadily declined from 47·4 to 33·8 in the seven preceding weeks, further fell to 30·4 last week. During the past eleven weeks of the current quarter the death-rate in the city has, however, averaged no less than 38·9 per 1000, against 24·2 in London and 22·4 in Edinburgh. The 194 deaths in Dublin last week showed a further decline of 22 from recent weekly numbers, and included but 11, or less than 6 per cent., which were referred to the principal zymotic diseases, against 21 and 23 in the two previous weeks. These 11 deaths from zymotic diseases included 4 from fever (including typhus, enteric or typhoid, and simple continued), 3 from whooping-cough, 2 from scarlet fever, 2 from small-pox, and not one from measles, diphtheria, or diarrhœa. The annual death-rate from these zymotic diseases did not exceed 1·7 per 1000 in Dublin last week; against 2·4 in London, 3·8 in Glasgow, and 4·5 in Edinburgh. The deaths referred to fever in Dublin showed a marked decline from recent weekly numbers, but the annual death-rate from this cause was more than twice as high as the average rate from the same cause in the twenty large English towns. Two fatal cases of small-pox were reported against but 1 in the five preceding weeks. The recorded deaths from whooping-cough and scarlet fever scarcely differed from those in the previous week. The deaths of infants, although slightly more numerous, were below the average; and those of elderly persons were fewer than in any previous week since the first of the year.

THE HUNGARIAN CENSUS.

The results of the Hungarian Census, which was taken on 1st December last, have just been officially published at Pesth, and show that the population of Hungary with Croatia, which was 15,417,327 in 1870, is not now more than 15,610,729. This shows an increase of only 193,402, or considerably less than one per cent. in the ten years. This slow rate of increase contrasts in a striking manner with that which prevailed in the German empire, where the increase of population during the five years 1875-80 was no less than 5·8 per cent. The Hungarian figures are undoubtedly surprising, more especially when the high birth-rate in that country is borne in mind, and they are said to have excited considerable sensation in Buda-Pesth. As might be expected, nearly the whole of the small increase during the past ten years is shown in towns, and it follows that the population of the greater part of the country, which is rural, has been stationary, if it has not actually declined. Various reasons are assigned for this signal check to the increase of population during the past ten years; among others, frequent outbreaks of cholera and epidemic fever, a succession of bad harvests, with floods and other natural calamities, which have more or less contributed to a considerable increase in the rate of emigration. One of the noticeable features of these Hungarian figures is that the excess of females in the population is comparatively small. At the recent census there were rather less than 103 females to each 100 males. This inequality is very much smaller than that which prevails in England, where the proportion in 1871 was 105 females to each 100 males. It appears, however, from the Prussian census, the results of which have just appeared, that the proportion of females in that population did not exceed 103·2 to each 100 males on 1st December last.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

THE ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL.

A report is published in the *Portsmouth Times and Naval Gazette* of an inquiry made at the request of the Admiralty by Lieut. Col. Percy Smith, R.E., into the water-supply, ventilation, and drainage of the Royal Portsmouth, Portsea, and Gosport Hospital. The report is of special interest, because it is accompanied by a series of marginal comments, inserted, our contemporary states, by the Chairman of Committees of the Hospital at the request of the Committee of Management. Colonel Smith's inquiry disclosed so many and such grave defects in the structural arrangements of the hospital, that, notwithstanding the Managing Committee appear to have carried out very generally his recommendations, the question is suggested, should not the whole building be given up and a new one built upon approved principles? It is evident from Colonel Percy Smith's description that the wards, with scarcely an exception, are not adapted, according to modern notions, to the uses and accommodation for which they were designed, and the statement of the Committee that they are never fully occupied as a sort of apology for their continued use, serves to confirm the impression got from the report that a new hospital is needed. The defects which Colonel Percy Smith describes in the arrangements for the water-supply, the drainage of waterclosets, baths, sculleries, slop-sinks, and of the drainage generally, are those peculiar to a hospital built nearly forty years ago, and many of these defects have been remedied. But it is evident that no tinkering can bring about proper ventilation of the wards, and we are quite unable to understand the comment of the Committee of Management upon Colonel Percy Smith's recommendation that the system of drainage of the hospital should be cut off from the town-sewer, by an intercepting chamber freely open to the outer air and with an S-trap on the sewer side—to wit, "This has not been done because of the diversity of opinion in regard of its desirability." Is it possible that a doubt on this matter exists within the limits of England, and almost within the shadow of Netley?

THE PLAGUE.

Further particulars received from the Levant enable us to form a pretty definite notion of the locality in which plague has again appeared in Mesopotamia. Information, however, respecting the outbreak comes in slowly, very slowly indeed, but the news is confirmed, and there is reason to fear that cases have been more numerous and more fatal than hitherto reported. The outbreak appears to have taken place within the district lying to the south of the Hindieh marshes and having the old bed of the river Euphrates on the east, the sea of Nedjef on the west, and the Shat el Atchan on the south. By means of cordons round the infected localities, also a cordon round the whole of the infected district, and quarantine stations established on the various routes of water communication with the districts to the East, the Ottoman Government is endeavouring to prevent the spread of the malady out of the infected area. Russia is also preparing to take measures of precaution in the Black Sea and Caspian Sea; Egypt has established quarantine against Syrian ports and ports in the Persian Gulf for ships coming thence with sickness on board, and the Italian Government has instituted a medical observation of ships coming from both Ottoman ports and ports in the Persian Gulf. Dr. Cabiadis, whose name is familiar in conjunction with plague in Mesopotamia, has been despatched by the Ottoman General Board of Health to the scene of the recent outbreak.

Typhoid fever is reported to be very prevalent in Goulburn, New South Wales.

THE SERVICES.

ARMY MEDICAL DEPARTMENT.—Brigade Surgeon Charles Carroll Dempster is granted retired pay, with the honorary rank of Deputy Surgeon-General; Brigade Surgeon Sampson Roch has been granted retired pay, with the honorary rank of Deputy Surgeon-General; Brigade Surgeon John Meane is granted retired pay, with the honorary rank of Deputy Surgeon-General; Surgeon-Major Joseph Gray, African Medical Service, has been granted retired pay, with the honorary rank of Brigade Surgeon.

Surgeon-Major R. Clifton, and Surgeons Le Motte and Chester have been detailed for duty with the 14th Hussars proceeding from India to the Transvaal.

Surgeon Dod, A.M.D., embarked on board the transport *Holland*, on the 22nd inst., in medical charge of a battery of artillery and drafts ordered to the Transvaal.

VACCINATION GRANTS.—The following gentlemen have received the Government grant for efficient vaccination in their respective districts: Mr. William Henry Latham, Congleton Union (second time). Mr. Linnington Ash, Holsworthy, N. Devon.

THE HOMERTON SMALL-POX HOSPITAL.

THE following are the conclusions of the Sanitary Committee of the Hackney District Board of Works on the Homerton Small-pox Hospital:—

"1. Your Committee have to report that, with the Medical Officer of Health, they visited the Small-pox Hospital, Homerton, and the adjoining neighbourhood, on Wednesday, December 29th. They carefully observed the approaches to the hospital, and consider them to be highly objectionable, especially that now used—viz., College-lane—on account of its narrowness and contiguity to the Homerton College Schools. They were informed by the Medical Officer of Health that boys, especially those attending at the Homerton College School, have occasionally ridden behind the ambulances while passing down College-lane. The Committee therefore consider that some means should be taken to prevent this practice in future by an alteration of the vehicles.

"2. The Committee would also point out another source of danger to the inhabitants of the neighbourhood arising from the ambulances being compelled to stop outside the gates during the time occupied by the porter or his wife in coming from the lodge. During this interval children frequently gather round the vehicles, and may thus become infected. In the opinion of the Committee this should be forthwith remedied by the present gates being always left open during the day, and inner gates erected within the hospital grounds.

"3. The interior arrangements, as regards the delivery of stores, are most objectionable, as tradespeople have to enter the hospital grounds, passing close to the windows of the wards, and deliver their goods either at the door of the stores or at the end of one of the corridors. The Committee saw soap being delivered from a van into the corridor by a man and a young lad, the latter of whom went inside the building repeatedly. The laundry is placed opposite to this corridor, and is ventilated almost directly into the street, which the Committee consider should be altered. The Committee have been informed that *employés* engaged in the delivery of goods from contractors have suffered from small-pox, showing that the Committee's objections to the position of the stores are well founded.

"4. The Committee also strongly object to the residences of the Medical Officer and Steward being situated in the centre of the hospital premises, and opposite to the Fever Hospital, as visitors and tradesmen going to these houses, as well as to the stores, are exposed to infection. They consider that these residences as well as the stores should be built in such a position as to admit the persons entering them from the public highway. The Committee would also point out the proximity of the mission-house to the hospital.

"5. After visiting the hospital the Committee went to Brooksby's-walk, carefully viewed the position of the houses, and are unanimously of the opinion that the houses Nos. 41 to 59 inclusive, and the mission-hall, which abut on the small-pox hospital, should be purchased by the Asylums Board and the former removed.

"6. Pending these alterations, the Committee are unanimously of opinion that the wall adjoining Brooksby's-walk, and that bounding the footway in the Grove, should be raised to a uniform height of 12 ft. at least, as the air from the open ventilators of the wards and laundry is at present directed at such an angle as to be carried over the last-mentioned wall, and the gardens of some of the houses in Brooksby's-walk abut on the hospital wall. These arrangements, in their opinion, are highly objectionable, as the windows in the end of the wards are within 24 ft. of the wall abutting on the Grove, and the mortuary is within 11 ft. of some of the gardens.

"7. The Committee are also of opinion that the best entrance to the hospital would be obtained by the managers of the Asylums Board purchasing a slip of ground from the Guardians of the City of London, so as to allow the patients to enter by the large gates of the Union Workhouse (which the Committee are informed are not now used), and pass along a passage between high walls leading into the hospital grounds. These outer gates could always be left open during the day, if a porter were kept in attendance near them, and a second porter were placed at the present lodge. The ambulances could then be admitted without delay or danger to the inhabitants of the neighbourhood, and without risk of infection to the friends of and visitors to the patients, who at present often stay outside the gates gossiping or making inquiries from the porter whilst an ambulance is passing by. This source of danger would be avoided by the plan recommended, as it would provide a separate entrance for visitors, and also enable the ambulances to pass along College-street, which is comparatively wide, instead of College-lane.

"8. If the entrance through the City of London Union grounds could not be obtained, a much safer means of access to the hospital than the present could be procured by pulling down two houses in High-street, Homerton, so as to open up Albert-street, which is about three times as wide as College-lane.

"9. The Committee consider that the present arrangements, which necessitate the use of the same entrance by small-pox and fever patients, and the passage of the latter through the small-pox hospital grounds, are decidedly objectionable, and would point out that a new entrance can be readily obtained from the Clifden-road. They are also of opinion that it is of the utmost importance, especially to persons residing in the vicinity of the hospital, that the number of patients in future admitted to the small-pox hospital should never exceed the number for which it is certified —viz., 102.

"The Committee finally desire to state their conviction that if the alterations recommended be carried out, the advantages arising from the presence of a hospital for the treatment of infectious diseases would, to a considerable extent, counterbalance the disadvantage arising from its present position."

Deaths from Small-pox in Hackney District, 1871-80: a statement prepared by the Medical Officer of Health (Dr. Tripe) and submitted to the Metropolitan Asylums Board by a deputation of the Hackney Sanitary Committee, 20th March, 1881:—

In Albert-street, Brooksby's-walk, College-street, College-lane, Farm-place, Holmbrook-street, Templar-road, and the Grove, being the streets nearest to the Small-pox Hospital, the deaths from small-pox amounted to 95 in ten years amongst 2314 people, and there were also 277 cases reported to me from these streets. These deaths give an annual death-rate of 4·1 deaths per 1000 population. In the streets within a quarter of a mile radius, in front and at the sides of the hospital, there were 167 deaths and 625 cases reported in the ten years amongst a mean number of 6823 inhabitants, giving an annual death-rate of 2·45 persons per 1000 population. Amongst 30,171 residents of the other small houses, occupied by poor persons, which are inspected annually, after deducting the deaths in, and population of, the above-mentioned streets, there were 484 deaths and 1745 cases, which give a death-rate of 1·6 deaths annually per 1000 population. The death-rate from small-pox amongst a mean population of 119,400 persons residing in the rest of the district was only 0·21 per 1000 population per annum, 261 deaths only having been registered amongst them in the ten years. The death-rate was 0·58 per annum per 1000 population for the whole district. These figures are necessarily calculated on the deaths, as cases in respectable houses are rarely reported to me, and the calculations would consequently be misleading. If all deaths in hospitals assigned to Hackney, or for which no addresses are given, had been included, a larger percentage of deaths in the poorer streets would have been shown. I was unable to assign fifty-three deaths in hospitals to the localities from which the patients had been removed, as their place of abode was not stated, but if these were added the annual death-rate would be 0·64 instead of 0·58 per 1000. The cases per 1000 population per annum in the ten years were as follows:—In the streets around the hospital 12·0; in those within a quarter of a mile radius in front and at the sides, in the other small houses, 5·8 per 1000 population. The number of deaths from small-pox in 1861–70, after allowing for those removed to the Highgate Hospital, was 173, which gives an annual death-rate of 0·167 per 1000 for the whole district. There were 15 deaths within the quarter of a mile radius, which, with 3 added for proportions removed to Highgate Hospital, gives 0·264 per 1000 population, against 2·45, or nearly ten times as many as in 1871–80. The proportion of deaths in the quarter of a mile radius in 1861–70 to the total deaths from small-pox was nearly 116 to 10, whilst in 1871–80 it was 412 to 10, or more than three times as many, showing that the inhabitants of these streets suffered to a far greater extent, as compared with the rest of the district, in 1871–80 than in 1861–70.

The following is a summary of the distribution of deaths in Hackney in the period 1871–80:—Deaths in streets adjacent to the Hospital, 4·1 per 1000 population; 164 deaths in streets situated within a quarter-mile radius of Small-pox Hospital = 2·45; 484 deaths amongst 30,177 poor persons living in other small houses = 1·60; 261 deaths amongst 119,400 population, excluding poor population and deaths = 0·21; 912 deaths amongst total population (total deaths) = 0·64.

In the period 1861–70 the total deaths in the same district from small pox = 0·167 per 1000; deaths within a quarter-mile radius of the Small-pox Hospital = 0 264. It is to be noted that the Hospital was not open during any part of the ten years 1861–70.

Deaths from Small-pox.		Per 100,000 population.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Lords on Thursday, the 17th, the Alkali Works Regulation Bill was read a third time and passed, as was also the Rivers Conservancy and Floods Prevention Bill.

The New Vaccine Establishment.

In the House of Commons, on Thursday, the 17th inst., in reply to Sir Trevor Lawrence, Mr. Dodson stated that Dr. Cory had been appointed medical director of the National Vaccine Establishment.

On Friday a petition was presented from Dreghorn for an alteration of the law relating to Scotch medical relief. Fifteen petitions from London and provincial towns were presented in favour of the prevention of vivisection. The annual Metropolitan Police report with regard to the working of the Contagious Diseases Acts was presented. On the motion of Viscount Lymington a return was ordered of the number of adult male paupers in England who had been members of friendly societies. In Committee on the Navy Estimates, a vote of £65,969 was agreed to for medical establishments at home and abroad, and a vote of £70,460 for medicines and medical stores, &c. The Alkali Works Regulation Bill was brought down from the House of Lords, and read a first time.

On Monday the annual return under the Lunacy Regulation Act, 1862, was laid upon the table. The second reading of the Vivisection Abolition Bill was deferred to May 11th. Mr. Puleston gave notice that he will move the rejection of the Alkali Works Bill, and Sir Sydney Waterlow gave notice that he will move that the Bill be referred to a Select Committee.

Army Medical Department.

Mr. Findlater asked the Secretary of State for War whether, having regard to the cases of wounds and sickness which had occurred amongst medical officers during recent campaigns, he would take into consideration the justice of extending to the Army Medical Department the privilege now enjoyed by all combatant officers of counting as full-pay service towards retirement any time on half-pay, not exceeding one year, when such half-pay had been necessitated by sickness incurred in and by the service; also such half-pay as resulted from the reduction of the department, not exceeding two years, as laid down in Army Circulars, March 1st, 1880. Mr. Childers said he feared he could not undertake to lay down the broad proposition that non-combatant officers were to have all the advantages of combatant officers, unless the converse be also accepted—that they were to have all the disadvantages. The regulation as to the retirement of medical officers had been so recently settled that he could not undertake to re-open the question, but when he had more leisure he would look into it.

Belfast Workhouse.

Mr. Biggar put a long series of questions with regard to the management of the Belfast workhouse, one of which was founded upon the assumption that the Local Government Board had allowed the schoolrooms to be converted into hospitals. Mr. Forster, after replying to the questions of workhouse management, stated that the inmates were well supplied with bedding and clothing, and the house was free from epidemic disease. The assumptions of the hon. member were not correct, and he saw no reason for altering the constitution of the Local Government Board.

On Tuesday a petition was presented from the grand jurors of the South Riding of the county of Tipperary, for inquiry into the subject of butter adulterations.

The Hampstead Hospital Case.

Mr. Firth asked the President of the Local Government Board whether the decision arrived at by the Metropolitan Asylums Board on Saturday last, to continue legal proceedings in the Hampstead Hospital case, had the sanction and approval of the Local Government Board; and whether the estimated cost of the legal proceedings already incurred, and at present paid or payable by the Metropolitan Asylums Board out of public funds, exceeds £20,000. Mr. Dodson replied that the approval of the Local Government Board was not requisite for the proceedings referred to, but he had no hesitation in saying that he had expressed his acquiescence in the decision of the managers, not to abandon the second appeal. He had no information as to the estimated cost of the proceedings. Mr. Firth thereupon gave notice that, in consequence of the answer of Mr. Dodson, he should oppose the clause in the Metropolitan Board of Works Money Bill which proposed to lend £50,000 to the Metropolitan Asylums Board.

The London Lock Hospital.

Mr. Hopwood asked the Secretary of State for War whether his attention had been called to the doubt which existed, whether the certifying of the London Lock Hospital, and the detention of patients therein under the Contagious Diseases Acts, 1866–9, was legal, inasmuch as that institution was not situated in any "place" to which those Acts apply. Mr. Osborne Morgan answered the question, which, he said, was a purely legal one. He did not feel that the doubt was well founded. The Acts in question authorised the Secretary of State for War, or the Admiralty, "to provide and certify for hospital purposes any building without any restriction as to place;" and he did not think that these general words could be taken to be restricted by the prior clause in the Act, confining the operation of the Act for police purposes to certain specified areas. He must add that that interpretation of the Act was fully borne out by the way in which the schedules were framed.

Animal Lymph.

Mr. P. A. Taylor asked the President of the Local Government Board if he could state to the House the source whence the new animal lymph is to be obtained—that is, whether the calves are now inoculated from a diseased horse or from a human being suffering under small-pox, or from what other source. Mr. Dodson replied that the Medical Department hoped to commence their series of calf vaccination from a well-ascertained case of spontaneous cow-pox. If such lymph could not be obtained the Board would commence their series from the well-known lymph at the Hague or Brussels station, where it had long been in use.

During the debate on Mr. Chaplin's motion concerning imported cattle disease, Dr. Lyons took the opportunity to make a strong appeal to the Government to establish in Ireland a veterinary college, which would enable veterinary students to be educated and trained in the country instead of having to go to London, Edinburgh, or Glasgow, as at present. Dr. Lyons stated that this subject had been unsuccessfully agitated by Irish members for the last fifty years.

On Wednesday a petition for inquiry into the East India Army Medical Department was presented from William H. Harris. A petition of the registered medical practitioners in Ireland was presented in favour of an alteration of the Medical Acts. Sir R. Cross gave notice that on Tuesday next he will move for a Select Committee, to consider the working of the Artisans' Dwellings Acts.

On Thursday Mr. P. A. Taylor gave notice of a further question to Mr. Dodson on the subject of vaccination—viz., whether in view of the increase of mortality through the use of bad lymph, the Government would bring in a Bill to abolish compulsory vaccination.

Small-pox in Kent.

Mr. Ross asked the President of the Local Government Board whether his attention had been called to an outbreak of small-pox in Boxley parish, Hollingbourne Union, Kent, where, apparently from the medical attendant not having taken precautions to isolate the case, five other cases had since occurred (one ending in death), which were traceable to infection caught from the said case. Mr. Dodson, who was most indistinctly heard in the gallery, said his attention had been called to the matter, and from inquiries he had made it appeared that a labouring man, being taken with small-pox, his medical attendant ordered his removal to the hospital. His wife was then attacked, and died after giving birth prematurely to a child. Two relatives who attended the funeral were also attacked by the disease, but in the mildest form. A competent nurse was procured for the man and his wife, and the usual precautions, including the free use of disinfectants, were taken to prevent the disease spreading by the directions of both medical men who attended, neither of whom, in his opinion, was to blame.

Correspondence.

"Audi alteram partem."

THE BIRMINGHAM HOSPITAL FOR WOMEN.

To the Editor of THE LANCET.

SIR,—You have been good enough to copy a report of my speech from the *Birmingham Daily Gazette* and to allude to it as a "mass of nonsense," and further to assume ignorance on my part of the literature of diseases of women. I am quite prepared, however, to abide by what I said as perfectly correct. The statistics of our operations for the removal of *ovarian tumours* are better by far than those of any hospital statistics yet published, and I challenge you to show that this is nonsense. The case of cholecystotomy, recently published, and some of hepatotomy shortly to be published, amply justify what I have said about the hospital doing work never attempted before in any institution, and only once previously in private, and then not successfully.

The insinuation at the end of the paragraph that we perform operations which are not legitimate is hardly a worthy one for the leading medical journal to make. In another part of your issue you speak of "spaying" as an operation still *sub judice*, and that is the only operation upon which your insinuation can be directed. We are giving it a trial, and have at least established the conclusion that it can be justified by a low mortality, and that is more than has been done anywhere else. Whether it will be further justified by its ultimate results yet remains to be proved, though I am quite satisfied it will, and I cannot help feeling that such a paragraph as yours can only tend to excite prejudice, and prevent the formation of a fair conclusion.

I am, Sir, yours, &c.,

Birmingham, March, 1881. LAWSON TAIT.

⁂ We are sorry to find Mr. Tait unable to disclaim the paragraph quoted in last week's LANCET. In proof of our statement that operations are done elsewhere with success at least equal to that obtained at the Birmingham Hospital for Women, we would quote Marion Sims, who in April last wrote as follows: "Keith has cured of his last hundred cases (ovarian tumours) ninety-seven per cent., seventy-three of these in succession without a single death."—ED. L.

EMPYEMA AND ITS TREATMENT BY FREE INCISION, IRRIGATION, AND ASPIRATION.

To the Editor of THE LANCET.

SIR,—I aimed at being just and not severe in my criticism of Mr. Moxhay's paper. He certainly stated that he was likely the first to adopt Fraentzel's method in this country, but as he disclaims pretension to priority in his letter, I willingly pass this over.

Mr. Moxhay may be assured that I read Fraentzel's article on Pleurisy, and while I admire the soundness of his opinions on most points, I confess my inability to concur with him always. Fraentzel holds that a pneumothorax is impossible without the admission of external air. Dr. Markham Skerritt and others demonstrated years ago that gas could and did accumulate without such admission, and I have verified pathologically that this is decidedly correct.

Mr. Moxhay says he may have introduced germs through injecting water; now this is what I object to. Would Lister do this? and, if not, why does Mr. Moxhay persist in murdering the expression, "perfect Listerian precautions"? Does he forget how Dr. W. Roberts, in his celebrated experiments, found that by injecting five drops of hypodermic solution of morphia into one of his flasks of steralised beef-tea he could produce full putrefaction in forty-eight hours? But Mr. Moxhay even asserts that water at 100° to 103° Fahr. may have destroyed, or rendered harmless, these micro-organisms. This, however, is a *principii petitio.* I would refer him to the literature of the subject, and he shall find that, although they are neither Zulus nor Boers, yet they are unwilling to die without a struggle. The above temperature would rather favour their development. Dallinger and Drysdale have shown that while 104° Fahr. suffice to kill adult septic monads, their spores are capable of germinating after subjection to a heat of 300° Fahr. for ten minutes (W. Roberts). Now, although no harm resulted through injecting water in Mr. Moxhay's case, it does not follow that his proceeding is universally applicable; if this were so, then the principle on which Listerism is founded would be made assailable.

I never objected to a free opening—quite the contrary. It is to the proceedings with which "free opening" is associated that I object.

Mr. Moxhay will please observe that "empyema proper" and "circumscribed empyemic abscess" are surgically similar and proper. We have now more definite information about the case though. There were clearly two collections of pus encapsuled by false membranes, and this fact of itself goes to teach us how we should explore the pleural sac in such cases, and break up, as far as possible, all intersections early. I am, Sir, your obedient servant,

Lichfield, March 14th, 1881. JOHN LOWE.

CATGUT LIGATURE IN THE TREATMENT OF ANEURISM.

To the Editor of THE LANCET.

SIR,—Having had some experience in the ligature of arteries with catgut, may I ask for space in your columns to add my mite to the discussion which is now going on *à propos* of the paper recently communicated by Messrs. Treves and Macarthy to the Medical and Chirurgical Society?

Mr. Treves's case was one in which the carotid and subclavian arteries were both tied in the same patient for innominate aneurism, the carotid first by Mr. Adams, the subclavian, three weeks later, by Mr. Treves. Mr. Macarthy's was one in which the subclavian was tied for axillary aneurism, and amputation at the shoulder-joint became necessary from bursting of the tumour two months afterwards. Both patients died; the first one hundred and eight days after the ligature of the carotid, the second sixty-four days after ligature of the subclavian. Of the three arteries tied only one was permanently obliterated, the other two became pervious after a time, although with considerable narrowing of the channel. Antiseptic treatment was adopted in all three, and answered perfectly in two—viz., Mr. Adams's carotid case and Mr. Macarthy's subclavian case, both wounds uniting rapidly by first intention. It failed in Mr. Treves's case, in which the wound opened and suppurated freely; and this was the only one of the three in which the artery was permanently obliterated.

The inference sought to be drawn from these cases is that rapid and immediate union may be injurious by not exciting sufficient inflammation and effusion around the vessel—the repair being, in fact, too perfect; whereas when there is suppuration greater thickening and solidification will be ensured. It is against this doctrine, which I consider to be illogical and misleading, that I write to protest. It seems clear to me, from the account given, that the two failures arose from the ligature not being effectually applied; and the one success was obtained, notwithstanding the disadvantage of the suppuration, because the vessel was thoroughly secured. Mr. Barwell pointed out in THE LANCET for March 5th that Mr. Adams and Mr. Macarthy used a double and then a single hitch in tying their knot, while Mr. Treves used a single hitch, repeated in the usual manner. This probably had some influence on the result, as the double hitch is *clumsy*, and difficult to draw tight as well as to maintain at the required tension while the second hitch is being tied; consequently the inner coats were completely cut through in Mr. Treves's case, but only very incompletely so in the other two. This seems to me to be clearly shown by the description, the inner coat in those two cases being uninterruptedly continuous from the proximal to the distal part of the vessel. This incomplete division of the inner coats was probably the cause of the entire absence of coagulum, which is such an important factor in the process of repair.

My own experience of the catgut ligature has been uniformly satisfactory. I have used it on the femoral artery nine times, on the external iliac twice, on the carotid artery three times, on the common femoral once, and on the brachial, radial, and ulnar each once. In none has there been secondary hæmorrhage, failure to obliterate the vessel, or other mishap. Some of the wounds have suppurated freely; latterly they have all healed by first intention under antiseptic treatment.

I look upon this result as dependent upon the special care which I have always taken to thoroughly divide the inner coats, and to observe that the first hitch does not slip while the second is being drawn tight, and I always add a third for additional security. It is the more necessary to attend to these points in using catgut in consequence of its stiffness and slipperiness as compared with silk, if it is not sufficiently softened in carbolic solution just before being used. If the inner coats are cut through, and the ligature tightly tied, I believe that complete obliteration will be brought about in almost every case, and even in spite of suppuration occurring. It was because this was not effectually done that these two failures took place, and they do not afford a particle of reliable evidence that suppuration is an end to be either aimed at or desired. On every principle of surgery there must surely be additional safety in securing immediate union by the plastic operations of nature, uninterfered with by the degenerative inflammatory action which suppuration implies. Catgut, if of proper quality, and properly applied, is, in my opinion, by far the best material yet known for ligature of arteries, whether in their continuity or otherwise; but if the well-established rule in surgery, that the inner coats must be divided by the ligature, be not carefully observed, and if, as there seems to be some prospect, a return should be made to the long-abandoned practice of using broad ligatures, and attempting merely to approximate the sides of the vessel, I venture to predict that it will not be long before more failures will be heard of.

I have had four opportunities of observing in post-mortems the changes effected by the catgut ligature. I will not go into the details of the cases, as it is unnecessary for my immediate purpose. Briefly, the following were the conditions met with:—

1. Ligature of external iliac for hæmorrhage; death after sixty hours. Ligature firmly in position, and but slightly changed; internal coats divided; firm conical coagulum above and below, adherent by their bases to the seat of ligature, and also to the sides of the vessel.
2. Ligature of common femoral; death in eleven days; wound healed by first intention; ligature completely absorbed; vessel firmly closed; divided edges of inner coats visible, and turned inwards; firm conical coagulum above and below, adherent as in the first case.
3. Ligature of superficial femoral; death after twenty-eight days; wound suppurated freely, but suppuration did not reach down to the vessel; artery firmly closed, and constricted at seat of ligature, which had disappeared; firm conical coagulum adherent, as in the other two cases, but fainter in colour.
4. Ligature of external iliac for hæmorrhage; death in thirty days; sloughing of wound extending towards artery, but not reaching it or affecting peritoneum; artery firmly closed and constricted at seat of ligature, which had disappeared; firm, pale coagulum for some distance above and below, and apparently undergoing absorption.

The deaths in these cases were from causes quite independent of the ligature. The uniformity of the result as regards coagulation and closure is remarkable, and goes far to show the desirability of thoroughly dividing the inner coats. The use of a substance which will be removed by vital absorption, the ends of which may, therefore, be cut short, is a great advantage, as it appears from the last two cases mentioned that plastic effusion may take place around the ligature and vessel, so as to shut them off from unhealthy processes which may be going on in the superficial parts of the wound.

I am, Sir, your obedient servant,

Norfolk-square, March 14th, 1881. JAMES R. LANE.

THE CHLOROTIC MURMUR.

To the Editor of THE LANCET.

SIR,—Dr. Balfour entirely ignores my explanation as to how I came to mistake *his* views. He surely must admit that it is possible to miss a paper even in THE LANCET. Having missed his paper, I maintain, firstly, that I was entitled to consider the views expressed in his work on the heart as representative of his opinions; and, secondly, that the conclusion at which I arrived after studying his sixth chapter—viz., that "he denies that the so-called basic murmurs of anæmia are ever arterial" was a logical conclusion, justified by his argument as a whole, and by the passages which I quoted in my last letter in particular.

I have already expressed regret that I should have coupled Naunyn's name with the chlorotic murmur. As an extenuating circumstance, I was, I think, justified in stating that such trustworthy authorities as Dr. Bristowe and Dr. Fothergill had come to the same conclusion on this point as myself, and I am glad to know that neither Dr. Bristowe nor Dr. Fothergill takes exception to my having done so.

The explanation which Dr. Balfour gives of the reduplicated second sound in mitral stenosis is not mentioned, much less accepted, by any writer to whom I have been able to refer. (Since this paragraph was originally written I have learned from Dr. Balfour that the explanation is his own.) The same argument which Hayden brings against the theory that the reduplication is due to asynchronism in the closure of the segments of either sigmoid valve seems to apply with equal force here.

Hayden says: "I have repeatedly made the following observation, which seems conclusive as against the univalvular origin of double second sound. Whilst a double second sound was equally audible at the orifice of the aorta and pulmonary artery, but most distinctly so at a point intermediate to, and equidistant from both, a single second sound only existed at the distance of an inch or so external to either orifice in the horizontal line. Manifestly if derangement of synchronism in the closure of the segments of either set of valves had been the cause of reduplication, the latter would have been audible to an equal distance from the orifice in the directions inwards and outwards, and it would have been most distinct at the orifice itself, and not midway between the two orifices."—(Diseases of the Heart, p. 127).

But, further, is it a fact that the systolic closure of the valves, which Ceradini describes, is attended by any sound at all? I understand that the distinguished Professor of Physiology in the University here is in the habit of teaching that the second sound is not due to the closure but to the stretching which follows the closure. Dr. Fothergill writes me that in his opinion the systolic closure of the valves, in a fluid in equilibrium, could not cause an audible snap.

I am, Sir, your obedient servant,

Edinburgh, March 18th, 1881. BYROM BRAMWELL.

PRIVATE DISPENSARIES.

To the Editor of THE LANCET.

SIR,—I have noticed various allusions of late in your valuable journal to what you call "private" dispensaries, and generally of an unfavourable character. The profession generally will sustain this representation. I was waited on a few weeks ago by the unqualified assistant of a well known proprietor of these cheap dispensaries. His object was to beg a few shillings under the following circumstances: He and his other unqualified colleagues had all at one fell swoop been discharged by his master, and, as his wages were only 25*s.* a week when in work, he was impecunious. He told me that he saw most of the patients and attended a good deal of the midwifery. Such a system as you point out in last week's LANCET is deluding to the working classes and discreditable to the men who carry it on. I have noticed, too, a tendency to make dispensaries rather with a view to sale than practice, by which innocent men—as pointed out by your correspondent, L.R.C.P. Edin. (THE LANCET, Feb. 5th)—are lured into very delusive purchases. I hope you will keep your vigilant eye on this undignified style of work.

I am, Sir, your obedient servant,

March, 1881. L. S. C.

MANCHESTER.

(*From our own Correspondent.*)

MONSALL FEVER HOSPITAL, it appears, is larger than is required for infirmary patients, and for those for whom provision is reserved on behalf of the city of Manchester, and that it has been the custom to admit patients from the suburban townships, as well as pauper patients, on certain terms. The annual loss to the infirmary in keeping up an establishment so much in excess of its requirements is, in round numbers, £1500 per annum, and the Board of the Infirmary have come to the conclusion that the present arrangements with the sanitary and poor-law authorities must be so revised as to prevent any further encroachment upon their funds. An adjourned conference on the subject was held on the 17th inst., the Infirmary Board being met by representatives of the health department and most of the local boards of the outlying districts. Considerable discussion took place as to the best and most equitable mode of distributing the excessive expenditure, the following resolution being ultimately adopted:—"That an arrangement be made that will distribute the ascertained annual loss of £1500 on the Monsall Fever Hospital, in fair proportions, amongst the several sanitary authorities of Manchester and the district, and that the said arrangement be calculated upon the mean percentage of the population and rateable value of property, and, further, that a charge of 3*s.* per head per day be made for each patient sent; this arrangement to be in force for three years." This scheme bids fair to make good the deficiency upon an equitable basis, and relieve the infirmary funds of an expenditure which presses hardly upon them, and ought to be accepted by the authorities, as the infirmary, a public charity, should not be a loser in a matter which so deeply concerns the health of the city and district.

Last week Mr. Cornelius Neale Dalton, the inspector of the Local Government Board, held an inquiry at the Manchester Town Hall in reference to an application which has been made by the corporation for a provisional order to enable them to acquire *inter alia* certain powers of raising money, and providing privies and ashpits in buildings where manufactures were being carried on; with these by-laws I do not propose to deal, but the 5th section greatly affects the medical profession of this city, in so far as the corporation asks power to require a notice of cases of infectious diseases to be given to the medical officer of health by the occupiers of premises when such cases occur, and also by the medical man in attendance on such case, and to provide for his remuneration for each case reported. It was stated as a plea for the necessity of compelling householders and the medical attendant to inform the sanitary authority of the existence of infectious diseases that last year the number of deaths in the city from infectious diseases was 423, and assuming that for every death eight cases recovered, the large number of 3884 cases would be reached, and yet only 85 cases were removed to Monsall Fever Hospital, and 94 to the Children's Hospital during that period. The corporation were further of opinion that it is only by systematic information given by medical men who are brought into contact with such cases that infectious diseases can be adequately dealt with.

A deputation of the Parliamentary Committee of the Medico-Ethical Association, consisting of its President, Dr. Lloyd Roberts, and its Secretary, Dr. Pierce, together with the President of the Society, Dr. John Roberts, Dr. Peatson, and the Honorary Secretaries, waited upon the inspector with a view of giving support to the general principle contained in the by-law quoted above. After considerable discussion the inspector decided to recommend the responsibility of reporting the cases to be laid, as the corporation desired, on both the householder and the medical attendant, but fixed the fee to the latter at the rate of two-and-sixpence per case. The forms of infectious disease scheduled were typhus, typhoid, variola, rubeola, diphtheria, and cholera. The medical profession here owes a debt of gratitude to the Medico-Ethical Association for their prompt action in the matter, for in the absence of their representations it is problematic whether an adequate fee would have been allowed for the reports.

At the Royal Infirmary Mr. Hardie is adopting a somewhat new method of dressing stumps and other amputations with much success. He covers the wound with a sponge dipped in an antiseptic solution, and retains it *in situ* by means of an elastic bandage; he does not remove the dressing for several days, and, as a rule, obtains primary union and no purulent secretion. I hope Mr. Hardie will explain his method in detail in your columns at no distant date.

GLASGOW.

(*From our own Correspondent.*)

THE number of changes which have taken place in medical circles in Glasgow within the last few years is quite remarkable, and it seems as if we were shortly to have another very considerable rearrangement of offices and places. The present excitement is caused chiefly by the vacancies in Anderson's College, the Western Infirmary, and the medical officership to an important insurance company. Judging by the number of candidates who are striving for the post, the last-mentioned prize appears to cause most stir; it is a noteworthy fact that the President of the Faculty of Physicians and Surgeons is canvassing as a candidate for it. In the Western Infirmary one physician and one surgeon are to be appointed to the new wards recently opened; for these offices also the number of claimants is very large. For the Chair of Midwifery at Anderson's College the principal candidates are Dr. A. Wallace and Dr. W. L. Reid, in either of whom the directors of the College would find a man well qualified to uphold the dignity of this important extramural school.

The Lord Provost of Glasgow, who seems to have made the sewerage question his own, announced recently that in a short time a sewerage scheme, likely to be the one most suitable for Glasgow, would be made public. If his lordship is right we shall all have reason for thankfulness, as the Glasgow sewerage question appears at present to be in as great a tangle as ever.

I hear it reported that in Mount Florida, a suburb of Glasgow, there is quite an epidemic of typhoid fever. The milk supply is blamed, but this part of the question is still under investigation.

PARIS.

(*From our own Correspondent.*)

THE measures being taken by the Municipal Council to replace the religious sisterhoods in the Paris hospitals by lay superintendents, or as it is called the *laïcisation* of the hospitals, have already created widespread dissatisfaction, and are likely to be the cause of serious trouble. The *France Médicale*, which has become the mouthpiece of the tolerant party, has published two protests against the expulsion of the nuns, which are signed by ninety-five hospital physicians and surgeons, and this number will no doubt be largely increased. It must not be supposed that the question at issue is one of religion. The majority of those who signed the protests would resent the accusation of "clericalism" as they have resented the persecution of the sisters, and the real motives of their conduct are entirely independent of creed. The true reason is to be found in a letter addressed by M. Desprès, with his characteristic bluntness, to the Prefect of the Seine, and published some time back by the medical press. No one can deplore more than the writer of this document the proselytising tendencies of many of the nuns; but, notwithstanding this defect, twenty-six years' experience in the hospitals has proved to the surgeon of La Charité that a secular attendant is worse for the patient. "A lay woman," says M. Desprès, "may be married and the mother of a family; when she will take as much time as possible from her duties for the management of her household." In this case the patient, left to the tender mercies of an often brutal *infirmier*, is not in an enviable position. "The lay superintendent, moreover, may keep the rings, earrings, and other trinkets which the nurses often take from the dying when they are not surrounded by the friends or properly watched. Such a temptation does not exist for the nun. The lay woman may have a child or husband ill, and she will not hesitate to take some dainties from the hospital for her own table." In wards for the reception of contagious disease, such as small-pox and diphtheria, a married woman will either neglect her work or run the risk of carrying infection abroad, and if she dies at her post it is a calamity for her family. But when a nun falls a victim to disease, "she dies alone, and is at once replaced by another. The thing is so much a matter of course that it has never occurred to anyone that her name should be recorded on a memorial tablet." From an economical point of view, change is also unadvisable. The religious communities cost the administration at the rate of £8 per head, and the members are fed and lodged together. A lay superintendent, on the other hand, is paid £24, and separate board and rooms have to be found in the hospital.

M. Desprès has studied the working classes very attentively, and he gives it as his opinion that patients who would vote in secret for the maintenance of the *religieuse* are the same who in public meetings and with their comrades shriek for the destruction of gods, churches, and ministers, with the greatest clamour. Even amongst the upper classes, he says, will be found many who declaim against the nun for the sick in hospital, but who themselves engage her in illness, because she does not get drunk or pry into cupboards. Without going into the same details as M. Desprès, the writers of the protests against *laïcisation* urge that the change is contrary to the interests of the patients.

Obituary.

DR. T. E. MACLEAN.

A RECENT number of the *Egyptian Gazette* gives a few particulars of the career of the late Dr. T. E. Maclean, whose death at Cairo we announced some weeks ago. After taking the degrees of M.B. and B.S. at the London University, and filling various posts at London hospitals, Dr. Maclean resolved to devote himself entirely to diseases of the eye. Symptoms of chest weakness manifesting themselves, he was strongly recommended by eminent physicians in London to go to Egypt. This advice he followed, and established himself at Luxor, the central point of Upper Egypt for Nile travellers. By his own personal efforts he there opened a small hospital, which was highly valued by the natives, who crowded to it for medical advice and operations. Dr. Maclean ultimately broke off his connexion with Luxor and settled permanently in Cairo, where he gained for himself a considerable reputation as an oculist ere he was carried off by the disease that had for several years more or less crippled him.

Dr. Maclean was most popular as a student, his steady perseverance and honesty of purpose in all he undertook, also his patience when teaching, were fully appreciated and acknowledged by the students electing him the President of the University College Medical Society.

JOSEPH BINDLEY TALBOT, L.R.C.P. LOND., &c.

THE late Mr. Talbot received his early education at the Park near Sedgley and at Douai in France. Having shown a predilection for the medical profession, he became a pupil of Messrs. Walker and Ashmead of Brierley Hill, and afterwards a student of the Birmingham School of Medicine. He was successful in carrying off the medals in anatomy and physiology, and attaining the senior prize in clinical medicine at the Queen's Hospital. Having filled the posts of Resident Clinical Assistant Physician and Resident Obstetric Physician at the Queen's Hospital, he obtained the appointment of Assistant Physician to the Bickton Asylum, Shrewsbury, and won the esteem of all connected with the establishment. He was afterwards appointed Medical Officer of Health for Kingston, Jamaica, but the office of Assistant-Physician to the Lunatic Asylum there becoming vacant, he succeeded to the post. Subsequently he practised at Swan River, Orange Valley, and latterly at St. Ann's Bay. Possessed of more than ordinary abilities and many accomplishments, he combined with them a high spirit and generous disposition; many of his teachers and fellow students will not readily forget his genial nature or fail to regret that his light should have gone out so soon. The deceased gentleman had been called up during the night, and appears to have been working hard all the morning, only ceasing for an interval to play and sing one of his accustomed songs. He expressed himself as feeling unwell; but hopefully expected to be better after a nap. He proceeded to the hospital, and, after writing some prescriptions and leaning forwards upon the table with his head resting upon his hands, was found by the dispenser in a state of insensibility. He was removed to his residence, but never regained consciousness.

Mr. Talbot has left a young widow and two daughters, as well as the old folk at home, to deplore his loss. A post-mortem examination showed that death had occurred from heart disease, the particulars of which are not forthcoming.

SURGEON ARTHUR TERMYN LANDON.

SURGEON LANDON, whose lamented death from wounds received in action at Majuba Hill we have already recorded, was but twenty-nine years of age, and had only received his commission for three years. This gallant young officer highly distinguished himself whilst at Netley, where he proved himself to be *facile princeps* amongst the army medical candidates of his session as regards his professional attainments by passing out first on the list and carrying off the prize for Military Surgery, whilst his genial qualities made him a universal favourite. The news, therefore, of his early death will be received with feelings of deep sorrow by all the candidates for commissions of the summer session of 1878, not unmingled with a sentiment of admiration for the gallant way in which he met his death in the service of his country.

Medical News.

APOTHECARIES' HALL.—The following gentleman passed his examination in the Science and Practice of Medicine, and received a certificate to practise, on March 10th:—

Pigott, Peter, Dulwich.

The following passed on March 17th:—

Atkinson, Thomas Ruell, Fleet-street.
Hagyard, Robert, George-street, York.

The following gentlemen also on the same day passed the Primary Professional Examination:—

George Neale, London Hospital; Henry Roberts, St. Bartholomew's Hospital; Thomas Taylor, Middlesex Hospital.

COLLEGE OF PHYSICIANS IN IRELAND.—During the March examinations the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—James Stuart Brooke, Harry Lysaght Hoops, James Quirke, H. J. Wyatt.

MIDWIFERY.—Harry Lysaght Hoops, Clement Mallins, Vincent Adolphe Passanha, Godfrey Forrest Reid, Frederick Thomas Skerrett, Richard Charles Studdert, H. J. Wyatt.

The under-mentioned Licentiates have been admitted Members:—

John Joseph Dingenan, George Alexander Moorhead, Richard Foster Owen, Joseph Michael Redmond, Richard Gelling Tyner.

MR. JOHN HANDLEY, late of Newark-on-Trent, bequeathed £100 to the General Hospital, Nottingham.

THE Prince of Wales has fixed Monday, the 9th of May, for the festival dinner of the Royal Hospital for Children and Women, Waterloo-road, at which his Royal Highness will preside.

MR. J. D. T. RECKITT, on resigning the post of house-surgeon to the Newark Hospital, was presented by the governors with a purse of thirty guineas, as a mark of their esteem, and of their consideration for his past services.

THE total proceeds thus far accruing from the Hospital Saturday and Sunday collections at Manchester, amount to £5752 3*s.* 5*d.*—a sum slightly below that realised in 1879.

HOME FOR PROTESTANT INCURABLES, CORK.—During the past year a sum of £6375 was placed to the credit of the Building Fund, and the committee have in hand sufficient funds to carry out the necessary works they have entered upon.

THE full superannuation allowance has been awarded to Dr. F. J. Lynch, late medical officer of the Loughrea Union.

A MEETING was held in Dublin last week for the purpose of forming a Ladies' Association, in connexion with the Dublin Sanitary Association, for improving the condition of the homes of the poor of Dublin, and for the promotion of health reform amongst all classes of society. A provisional committee was appointed to prepare rules and to report at a future meeting.

THE "Charity Record" gives the following reminder of the necessity in making bequests to accurately describe the charities intended to be benefited. The Royal London Ophthalmic Hospital, Moorfields, was left £500 by a lady, but the institution not having been correctly named, claims were made by other hospitals, and, the matter being placed in the Court of Chancery, only £119 18*s.* has been awarded to the Royal London Ophthalmic Hospital.

IN the report read at the annual meeting of the friends of the Hertfordshire Seaside Convalescent Home, allusion was made to the frequency with which the true objects of the institution were overlooked by those who had the privilege of recommending patients for the receipt of its benefits. It has been found necessary in consequence to adhere rigidly to the rules regarding the admission of inmates, and to exclude such persons as may be sent in violation of the regulations.

EARLSWOOD ASYLUM.—On Tuesday last the thirty-fourth anniversary of this institution was held under the presidency of Mr. J. Colman, M.P. It appears there had been a marked falling off in the contributions last year, which is a matter for regret, seeing that only about one-third of the £30,000 expended in the maintenance of the Asylum had been paid by the friends of the patients. Some £2000 were contributed during the evening.

A COMBINED meeting of the Northern Counties, the North Western, and the Yorkshire Associations of Medical Officers of Health will be held at York, on April 7th, to consider the question of Infantile Mortality from Diarrhœa. The discussion will be confined to the following points—viz., 1st, The causes of diarrhœa, more particularly those indicating a specific or non-specific origin. 2nd, Is the infantile diarrhœa prevailing during the third quarter of the year a zymotic disease? 3rd, The pathology of uncomplicated diarrhœa. As the meeting will not be confined to members of the three societies, Dr. J. Mitchell Wilson, Doncaster, Secretary of the Yorkshire Association, will be glad to receive papers, or the proposal to speak at the meeting from other members of the profession.

AN influential meeting, under the presidency of the Lord Mayor of Dublin, was held last Monday for the purpose of considering the best site for the new science and art museum. The authorities at South Kensington wish to place the new building on Leinster Lawn—a proposal which is regarded by the majority of the citizens with disfavour,—have offered £100,000 if their suggestion is adopted, and have more than hinted that unless this plan is accepted a very much smaller sum will be forthcoming. The meeting unanimously adopted a resolution that the Kildare-street site should be selected, and pressed on Her Majesty's Government the justice and expediency of proceeding as expeditiously as possible to give effect to the provisions of the Dublin Science and Art Museum Act, 1877.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest*

BALL, C.B., M.D., M.Ch., F.R.C.S.I., has been appointed Medical Officer to the Grand Canal-street Dispensary District, Dublin.

BEVAN, W. Ll. P., M.B., C.M., has been appointed House-Surgeon to the Dorset County Hospital.

BRERETON, J. B., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the First District of the Bodmin Union.

CAWTHORNE, B. W., M.B., C.M., has been appointed Medical Officer for the Fifth District of the Stroud Union.

COLLINS, H. W., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer for the Fifth District of the Axbridge Union.

EDWARDS, D. T., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of the Pentyrch District of the Cardiff Union.

ENGLISH, Mr. E., has been appointed House-Surgeon at the London Hospital, vice Richardson, resigned.

FORD, J., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer for the Ninth District of the Axbridge Union.

JOHNSTON, H. M., M.D., L.R.C.S.I., has been appointed Medical Officer to the Stranorlar Union Workhouse and Fever Hospital, vice Love, resigned.

KEMMIS, H. M., L.K.Q.C.P.I., M.R.C.S.E., has been appointed Medical Officer for the First District of the Bridgwater Union, vice Hurman.

LOWE, W. F., F.C.S., has been appointed Public Analyst for the County of Carnarvon, vice Owen, resigned.

MORGAN, W., F.C.S., has been appointed Public Analyst for the Borough of Haverfordwest.

O'DONAGHUE, P., L.K.Q.C.P.I., L.R.C.P.Ed., L.F.P.S.G., has been appointed Medical Officer to the Hospital of the Loughrea Union, vice Lynch, resigned.

ORFEUR, C. H., has been appointed Medical Officer for the Nailsea and Wraxall District of the Bedminster Union, vice Adams, resigned.

PATTON, W. J., B.A., M.B., L.R.C.S.I., has been appointed Assistant Medical Officer to the Three Counties Asylum, vice Dr. J. S. Buck, resigned.

POTTER, S. R., A.B., M.B., has been appointed Public Vaccinator for Collumpton District, Tiverton Union.

SMITH, J., M.R.C.S.E., L.M., L.S.A.L., Honorary Medical Officer to the Royal Surrey County Hospital, has been elected Medical Officer of Health to the Rural Sanitary Authority, Guildford Union, at a salary of £200 per annum.

STEELE, W. C., L.R.C.P.Ed., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Newington Infirmary, Walworth.

WOOD, E. J., M.B., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Third District of the Maidstone Union.

Births, Marriages, and Deaths.

BIRTHS.

CARNE-ROSS.—On the 18th inst., at Chalmers-street, Edinburgh, the wife of J. Carne-Ross, Esq., M.B., C.M. (late Lieut. 73rd Regiment), prematurely, of a son, who survived his birth an hour.

ELLIS.—On the 17th ult., at Sitapur, Oudh, the wife of J. Ellis, M.D., Bengal Medical Service, of a daughter.

HARRTRY.—On January 27th, at Barkly Diamond Fields, South Africa, the wife of William Rosser Harrtry, L.R.C.P., M.R.C.S.E., J.P., of a son.

LAND.—On the 18th inst., at Bordyke House, Tonbridge, Kent, the wife of William J. Land, Esq., M.R.C.S.E., of a daughter.

LAW.—On the 22nd inst., at 20, Warrior-gardens, St. Leonard's-on-Sea, the wife of W. T. Law, M.D., F.R.C.S., of a son.

WINCKWORTH. — On the 11th inst., at Shefford, Beds, the wife of Charles Edward Winckworth, L.R.C.P.L. &c., of a daughter.

MARRIAGES.

MOORE—ARMSTRONG.—On the 15th inst., at Christ Church, Leeson-park, Dublin, John W. Moore, Esq., F.R.C.P., Physician to Meath Hospital and Cork-street Fever Hospital, to Louisa, youngest daughter of the late Edmund J. Armstrong, Esq., J.P. and D.L., of County Clare, and Lower Leeson-street, Dublin.

PURVES—ADIE.—On the 19th inst., at St. John's Church, Woodlands, William Laidlaw Purves, M.D., of Stratford-place, Oxford-street, W., to Elizabeth Adie, second daughter of Patrick Adie, of Worton Hall, Isleworth.

YEO—SICH.—On the 16th inst., at the Parish Church, Chiswick, Robert F. Yeo, Esq., Surgeon R.N., only son of Thomas F. Yeo, Esq., of Uplands, Delgany, County Wicklow, to Alice, eldest daughter of William Thrale Sich, Esq., of Chiswick.

DEATHS.

ASHFORD. — On the 18th inst., at Windsor Villas, Plymouth, John Butter Ashford, Esq., M.D., in his 59th year.

CHILDS. — On the 14th inst., at Tower House, Uxbridge, Archibald Prentice Childs, F.R.C.S.E. &c.

DANIELL.—On the 23rd inst., at 20, Cathcart-road, South Kensington, S.W., Sarah, the beloved wife of Richard Thomas Daniell, M.B., F.R.C.S.I.

DAVIES.—On the 13th inst., at Nice, Albert Davies, M.D., late of Maidstone, Kent.

ELLIS.—On the 19th inst., at his residence, Tower-street, Hackney, and late of Sudbrook-park, James Ellis, Esq., M.D., aged 77.

FORBES.—On the 20th inst., at Queen-street, Edinburgh, George Feddes Forbes, Surgeon-Major, H.M. Indian Army.

SPROTT.—On the 16th ult., at Kingstown, St. Vincent, West Indies, Robert Porter Sprott, M.D., Medical Officer No. 1 District, aged 59.

WHITE.—On the 14th inst., at Montague House, Bath, John Ludford White, M.A., F.R.C.S., formerly of Dowlais, aged 67.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

Monday, March 28.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. — Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M. ; on Tuesday, 9 A.M.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. The President will exhibit a Case of Paralysis in an Adult simulating Hypertrophic Paralysis and a Case of Double Facial Paralysis.—Dr. J. Milner Fothergill will make a few Remarks upon the Digestion of Fats, and exhibit some Specimens of Oils.—Dr. Stephen Mackenzie will give the Notes of a Case of Syphilitic Disease of the Spinal Cord.—Dr. Day, "On 'Tubercular Meningitis' and the Mode of Treatment."

Tuesday, March 29.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

ROYAL INSTITUTION.—3 P.M. Professor Edward A. Schäfer, "On the Blood."

Wednesday, March 30.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN. — Operations, 2½ P.M.

ROYAL COLLEGE OF PHYSICIANS OF LONDON. — 5 P.M. Croonian Lectures: Dr. Moxon, "On the Influence of the Circulation upon the Nervous System."

Thursday, March 31.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL. — Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

ROYAL INSTITUTION.—3 P.M. Mr. H. H. Statham, "On Ornament."

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM. — 8 P.M. Living Specimen.—Mr. Sebastian Wilkinson, "On a Case of Retinal Hæmorrhage."—8.30 P.M. Adjourned Discussion on the Relation of Optic Neuritis to Intracranial Disease. Dr. Stephen Mackenzie, Mr. Hutchinson, Mr. Couper, Dr. Gowers, Mr. Nettleship, Dr. Walter Edmunds, Dr. Buzzard, Dr. Brailey, and others are expected to speak.

Friday, April 1.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

ROYAL COLLEGE OF PHYSICIANS OF LONDON. — 5 P.M. Lumleian Lectures: Dr. Southey, "On Bright's Disease."

ROYAL INSTITUTION.—8 P.M. Sir H. S. Maine, "On the King in his Relation to Early Civil Justice."

Saturday, April 2.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Rev. H. R. Haweis, "On American Humorists."

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of The Lancet *to be addressed "To the Publisher."*

On the Relation of Temperature to Mortality.

A paper was read by Dr. Guy, F.R.S., at the last meeting of the Statistical Society, "On the Relation of Temperature to Mortality," as shown by the returns of Dr. Wm. Heberden, Dr. Thomas Short, and Dr. Scoresby-Jackson, and further illustrated by the experience of the German insurance office at Gotha for the half century ending 1878. Dividing the year into three periods of four months, the first comprising the period of greatest heat (June, July, August, and September), the second that of greatest cold (December, January, February, and March), and the third, or temperate period (April, May, October, and November), it appears that the first furnishes the smallest and the second the largest number of deaths, the third holding an intermediate place. This, however, applies only to the more temperate climates, for the returns for Marseilles and Montpellier show the highest number of deaths in the hot and the lowest in the temperate months, the cold furnishing the intermediate number. An examination of Heberden's tables brought out two important facts—1st, that the lowest mortality occurred at all ages in the summer, and, with the exception of infants and children under five years, the highest in winter; 2nd, that, with a solitary exception, the high mortality of the cold months increases, while, without any exception, the low mortality of the summer months becomes less and less as age advances. The author went into some detail as to the influence of temperature on the mortality by various groups of diseases, and also illustrated the power of cold in raising the death-rate of the aged by a comparison of the mortality above sixty in years, in which there was a marked difference of temperature. Dr. Guy said it was not a new truth that the highest death-rate prevailed during the coldest months, but it was a new truth that the three seasons in the year which presented the coldest, highest, and intermediate temperatures did present also a continuity, or, rather, a regularity of results which had not been previously pointed out. The paper gave rise to an interesting discussion, at the close of which the thanks of the meeting were voted to the author.

The letter of *Mr. A. Kisch* arrived too late for consideration this week.

Mr. Bowman.—An answer will appear in our next.

Subscriber had better apply to the Secretary of the B. G. A., 20, Golbourne-road, W.

CHRYSOPHANIC ACID IN PSORIASIS.

To the Editor of The Lancet.

Sir,—Having just seen in your last issue an account of the treatment of a case of psoriasis by Dr. Radcliffe Crocker (read before the Medical Society of London), in which one-half of the body was treated by chrysophanic acid and the other by turpentine, and where it was apparently shown that the one drug was quite as active as the other, I venture to communicate the following:—Professor Charteris, in a recent lecture to his class, described some cases in which it was very evident that chrysophanic acid acted constitutionally as well as locally. In one very severe case he, having previously very carefully wrapped up the arm and leg of one side in cotton-wool, applied chrysophanic acid (one drachm to one ounce) to the leg of the opposite side. In ten days the cure was complete, and on removing the cotton-wool from the other side it also was found to be quite cured of the psoriasis. This shows that the drug acts constitutionally as well as locally. Might this not be an explanation of the apparent efficacy of turpentine in Dr. Crocker's case?

I am, Sir, yours, &c.,

March 7th, 1881. A Student in Materia Medica,
Glas. Univ.

The Lifeboat Institution.

This enterprise has a strong claim on the sympathy and support of the community. As a means of saving life it appeals to the instincts of the medical profession, and must needs awaken strong interest. The institution has now 270 lifeboats in operation. In 1880, 577 persons were rescued from wrecks, and twenty-seven vessels were saved by the help of the society. It would be difficult to point to any institution more worthy of the pecuniary aid of the philanthropic.

House-Surgeon.—No.

SOME OBSERVATIONS ON BRITISH MINERAL WATERS AT THE PRESENT TIME.

To the Editor of The Lancet.

Sir,—For some time past I have been interesting myself in British mineral waters, and as I have come to certain conclusions respecting them, I shall be glad if you will insert this communication, with the hope of bringing the matter before the profession, and, through them, before the public.

It is not my intention at present to enter into the merits of any particular spring, but simply to gather up a few fragments, which I hope will be the means of inducing those members of the profession who live in localities where mineral waters exist to bestir themselves, and by every legitimate professional endeavour to bring their particular mineral water before the British nation.

I think that if some kind of general organisation or co-operation could be set on foot amongst all ranks of the profession, and especially among the consultants of London and other large towns, much might be done to save our great mineral springs. I have reason to believe that there is a move going on in the proper direction; at least such is my impression from the numerous communications received from medical men and others.

I do not for a moment undervalue the merits of most, nay, of all foreign mineral waters, but I contend that we have many mineral waters of equal value in this country. This is the opinion of many of the highest authorities in the land, from Sir Robert Christison and Sir Henry Thompson downwards. I have a letter from Sir Robert Christison so late as December 6th, 1880, on this very subject. He was kind enough to give me his opinion upon certain kinds of mineral waters, and amongst his general remarks he says, "There is no doubt that in search of relief from the use of most varieties of mineral waters our countrymen have for a long time past made it a senseless fashion to repair to the continental springs when they have comparatively at their doors springs of the same quality, beautiful surroundings, national amusements, and, above all, British comforts." He then goes on to compare British and foreign mineral waters, giving credit to many kinds of thermal waters, and also to the acidulous cold springs which abound on the Continent. In concluding his remarks, he says, "As to aperient saline springs, for which we Britishers have perhaps more occasion than for any others, so long as Leamington and Harrogate, &c., in England, and Airthrey at Bridge of Allan, in Scotland, are not drunk dry, there is no reason—no medical reason, I mean—why a man should deprive himself of his home comforts and submit to the annoyances of long journeys and continental deficiencies. The best means would be, if possible, to convince the consulting physicians of London of the folly of the present fashion."

Now, what are some of the mineral waters for which Great Britain is famous, where are they to be found, and what are some of the maladies which they remedy? Let us inquire.

1st. Salines.—Found at Leamington, Epsom, Cheltenham, &c., in England, and Bridge of Allan in Scotland. Complaints which they remedy: Chronic gout, rheumatism, dyspepsia, sciatica, hepatic, renal, and uterine disorders, paralysis, &c.

2nd. Sulphurous.—Harrogate and Leamington in England, Strathpeffer in Scotland: Skin diseases, rheumatism, dyspepsia, &c.

3rd. Alkalines.—Bath, Buxton: Rheumatism, gout, eczema, dyspepsia, &c.

4th. Iodo-Bromides.—Woodhall (stronger than any on the Continent): Syphilis, rheumatism, tumours, &c.

5th. Chalybeates.—Tunbridge Wells, Cheltenham, Leamington (in small degree), Harrogate, &c.: Anæmia, dyspepsia, &c.

These are a few British springs, and many of them will bear comparison with any foreign ones. Well, then, may Sir R. Christison ask "Why go abroad for the same thing?" Experience goes to show that those waters give greater benefit when drunk fresh from the wells and for a certain period. Let, therefore, consultants and medical practitioners generally combine to recommend our home mineral waters where they are likely to afford equal relief with the foreign ones, and depend upon it that all parties interested in the matter will benefit.

In a following paper I hope to bring forward the properties of our Leamington springs, and in the meantime I ask our professional brethren to combine, agitate, and write wherever they have valuable springs to write about. To show how necessary it is that something should be done in this way, I may say that at the present time in this town it is proposed to "build upon and partly shut up" a certain number of baths in connexion with the pump-rooms to make room for municipal buildings. Sir Robert Christison, when speaking of the decay of another inland watering-place, describes it as "the now despised, but once popular Bath." Can we do nothing to remedy the evil? I think we can.

I am, Sir, your obedient servant,

Leamington, Feb. 28th, 1881. F. William Smith, M.D.

A DISCREET BOARD.

THE question of the supply of stimulants to the workhouse having come up for discussion at the Preston Board of Guardians last week, Dr. Ridley said, that if spirits as stimulants were not allowed the Board would have to have recourse to drugs, which in many instances were far more costly, though spirits would often answer the same purpose, and at less expense. One of the guardians remarked that the medical officer was their master in this matter, and they should abide by his decision. It was then resolved that spirits be supplied as heretofore.

Dr. Edward Jones.—The fee rests with the coroner in a case when no inquest is held.

Anglo may obtain information from our advertising columns.

FLEXIONS OF THE UTERUS.

To the Editor of THE LANCET.

SIR,—I crave permission to have inserted this short letter. A communication from Dr. Herman appears in your issue of March 5th, containing some pointed remarks on a most important subject. They seem to me rather unfair. It is no doubt evident that the publication of isolated cases does not prove much, but, unless I am entirely mistaken, no one is more desirous of having "every case" recorded (if that happy consummation could be in any possible way arrived at) than Dr. Wynn Williams. For a period of about three years I have been a close observer of his practice at the out-patient department of the Samaritan Free Hospital, being specially interested in this particular subject. At his clinique all comers are most courteously received who desire to witness his practice. A great many cases returned again and again, most for symptoms not connected with former troubles. Some of the patients I accidentally met elsewhere. One was first of all under my own care in private practice, and is, like nearly all the others I have seen, a successful instance of treatment by this particular intra-uterine stem in question.

Thus far I can bear testimony that in no instance did I witness anything like dangerous symptoms follow the practice. Dr. Herman's use of the phrase "this startling statement" in his letter I regard as quite natural. It was the cause of my regular attendance at this hospital for so long a period.

I am sorry now to be unable from want of time to follow out my so far negative quest of unsuccessful cases, or rather for cases ending fatally, for surely no one supposes that success in every case is invariable, or even complete. I am, Sir, yours, &c.,

Warwick-road, S.W., March, 1881. ALEX. M. LANG.

J. H. B.'s questions have been mislaid. The degree can be obtained from the various universities of Europe. Our correspondent would find much useful information in a work entitled "Medical Education and Practice in all Parts of the World," by Herbert Junius Hardwicke, M.D., published by Churchill. The most useful work on Clinical Thermometry is Wunderlich's, published by the Sydenham Society.

C. H.—We cannot interfere in the matter.

Dr. Meredith should apply to the Secretary of the Manchester Provident Dispensary Association and to the secretaries of the Royal Albert Hospital, Devonport, and of the Royal Portsmouth, Portsea, and Gosport Hospital, both of which co-operate with provident dispensaries.

Beta.—We are not aware. The information may no doubt be obtained of one of the hon. secretaries of the Fund by addressing a letter to 11, New Burlington-street.

DISLOCATION OF SHOULDER-JOINT AND DEATH FROM CHLOROFORM.

To the Editor of THE LANCET.

SIR,—I have been struck, as doubtless others have also, with the comparative frequency of death from chloroform when the patient under its influence has been the subject of dislocation of the shoulder. The only death from chloroform I have seen was one of this kind. I well know that it is very much easier to reduce a dislocation with the patient under the influence of chloroform than to strain one's arms in pulling in a dislocation in the ordinary manner with the heel in the axilla. But the question arises, Is it worth the risk? Emphatically, No. The method I have adopted for over eight years, and have taught, has been to take an ordinary jack-towel, fix it with a clove-hitch above the elbow of the dislocated limb, and then put the other end over one shoulder, across the back, and under the other arm; then, placing my heel in the axilla, I use the weight of my body and the muscles of my back in making the extension that is to tire out the shoulder muscles of the patient—from two to three minutes generally effects this,—and then bringing the patient's arm towards the median line, the head of the humerus slips in. This method I have never known to fail, and by it I have several times reduced a shoulder dislocation when others had failed and were going to administer chloroform. It has also the advantage of not tiring the surgeon's arms.

I am, Sir, yours faithfully,

HERBERT A. LAWTON, L.R.C.P. Lond.,
Late House-Surgeon, Liverpool Royal Infirmary and
Poole, March 5th, 1881. Westminster Hospital.

JELLY-FISH.

MR. ROMANES, F.R.S., in his lecture at Trinity College, Mandeville-place, Manchester-square, last week, on jelly-fish, mentioned two or three facts respecting this interesting animal which, though well known to biologists, may be new to many. The lecturer stated that he had found by experiment that the fresh-water species were as intolerant of salt water as the marine species were of fresh. Jelly-fish were very various in form, but, although divergent in shape, they all presented fundamentally the same anatomical structure. However minutely cut up, each portion would develop into a perfect animal. The lecturer also showed that alcohol possessed an intoxicating power over jelly-fish.

"MAIN SEWER VENTILATION."

To the Editor of THE LANCET.

SIR,—Referring to the observations of Mr. Robert Rawlinson, that appeared in THE LANCET of January 15th, does it not seem rather anomalous that the utmost care should be exercised to prevent the entry of sewage gas into our dwellings, and yet the gas may be allowed to escape by means of the gullies, around which children may constantly be found playing? If the gas, when much diluted, can be shown to be free from disease germs or spores, I presume no danger may be apprehended; but, unless this be the case, would it not be better for Mr. Rawlinson to qualify his remark having reference to ventilation by means of the gullies, especially as his observations on such questions have much weight with many engaged in sanitary science? As one, I beg to subscribe myself A SANITARY ENGINEER.

March 17th, 1881.

TRACHEOTOMY TUBES.

To the Editor of THE LANCET.

SIR,—With reference to the observations in your journal on Tracheotomy, I would suggest that the tube used should be double—that is, one tube contained within the other. By that means the inner tube can be removed and cleansed, and then replaced with little trouble and great ease to the patient. Sponging, mopping, and the use of feathers, &c., would thus be avoided.—I am, Sir, yours truly,

Strand, March 15th, 1881. W. M. HILLES.

VACCINATION AND REVACCINATION.

To the Editor of THE LANCET.

SIR,—I find that some medical men in this neighbourhood are daily in the habit of making use of lymph from vesicles in cases of revaccination. If this be an unsatisfactory mode of performing the important operation of vaccination, publicity of the fact is most desirable. Trusting that you may agree with me as to the importance of the subject, and find space for this short letter, I remain, Sir, yours, &c.,

Earl's-court, S.W., March 24th, 1881. ALEX. M. LANG.

"HOME FOR LITTLE BOYS."

SIR STAFFORD NORTHCOTE very kindly and ably presided on Saturday last over the dinner celebrating the seventeenth anniversary of this benevolent institution, in which 300 little boys found something as like a home as it is possible to supply in the absence of the real one.

F. P. S.—There is no special work on the subject. See books on Physiology; Quain's Anatomy (last edition), Kölliker on Development, and Senff.

Mr. E. J. Day.—It is not desirable to revive the discussion of the subject.

SOCIETY FOR THE ABOLITION OF VIVISECTION.

To the Editor of THE LANCET.

SIR,—In reply to your leading article of the 19th inst., pray permit me to state publicly in your columns that the assertion therein made—viz., "their mode of carrying on the agitation has been, to say the least, unscrupulous and undignified," is without foundation in regard to the original Society for the Abolition of Vivisection.

In the *Morning Post* and *The Times*, of April and May, 1877, this Society disavowed any approval of the sensational and revolting illustrated placards which had been put up in the streets and public places of the metropolis and inserted in a penny weekly newspaper (the *Police News*), addressed to a certain class.

The Society—which gave the first great humane impulse to the public mind by its publications, the press, its numerous and costly advertisements and correspondence with eminent physiologists, and which obtained the appointment of a Royal Commission, and gave evidence on three days before it—has no connexion with persons who make a convenience of the cause, and seek notoriety or subsistence by a humane enterprise.

The Society had nothing to do with the "anti-vivisection" meetings got up in Peterborough and elsewhere, but regrets itinerant and incapable exhibitions as bringing discredit on the cause.

As to the Bill in Parliament, we repudiate it. Our opinion has always been that to introduce a Bill into Parliament before the country is educated is useless.

I remain, Sir, your obedient servant,

March 22nd, 1881. GEORGE R. JESSE, Hon. Sec., &c.

"INFLUENCE ON WOMEN OF SPECIAL BRAIN-WORK."

To the Editor of THE LANCET.

SIR,—I have read your leading article this week on the above subject with very much interest, where you show so clearly, to my mind at least, the injury done to the brain of the offspring by not so much the education of the woman as by the natural talent she has been endowed with.

I cannot think you spoil the woman by education, unless that education be in medicine and surgery; nor can I think that brain development is at all arrested in the offspring because the parent should be engaged as a medical practitioner; but I am convinced, from some experience too, that the brain of the offspring suffers from the study and occupation of the mother during pregnancy in literary pursuits.

One case in point: My wife is a literary woman of considerable reputation, having written and published several works. I am an ordinary individual, perhaps an average member of the profession. I have three sons, none of whom I could by any means educate sufficiently to enter any profession for want of brains enough to retain what they were taught. Yet they are smart fellows for other pursuits, and doing well at what I have placed them; but there is an entire want of literary taste in all three, and always a disgust to learning.

I have two daughters sufficiently intelligent, but no taste for medical literature, and although I have been disappointed at not having one of my sons in the profession, nothing would induce me to substitute a daughter, thus for ever to bury her womanly charms by changing her gender.

For a long time I have been favourable to women occupying the department of midwifery, and would willingly relinquish my right in that branch of the profession to them. When I was learning it I was obliged to recognise the authority of two celebrated French women as possessing the largest experience even in operations. Why not now give to English women the same right? I mean as a superior class of nurses doing the duty of general practitioners at present among the working classes, what in Ireland is generally done by midwives.

With regard to diseases of women, I fear it dips a little too deeply into anatomy, pathology, and physiology for them unless they are educated under the usual curriculum, and which, to my mind, is altogether out of place; but, were it not so, I say by all means give them that department as well.

I am, Sir, yours, &c.,

March 6th, 1881. M.D.

"MULTIPLE LIVER ABSCESS IN CONNEXION WITH DYSENTERY; DEATH."

To the Editor of THE LANCET.

SIR,—Anent the interesting case of the above, described by Dr. Henderson, of Shanghai, in THE LANCET, January 8th, 1881, p. 55, I would beg, with your permission, to state that about four or five years ago there was a similar case under the care, at first of Dr. Cameron MacDowall, and subsequently under my own. A full report of it, together with our remarks on the symptoms and morbid appearances, we at the time published, conjointly, in the columns of the *Indian Medical Gazette*. We then seized the opportunity to discuss briefly the pernicious influence of malaria upon the hepatic and splenic functions as it appeared to us, and we also took occasion to indicate the futility of operative measures in cases of multiple—we then preferred to use the word "multiple" ourselves—abscesses of the liver. Perhaps Dr. Henderson and our other medical brethren would like to refer to our article, in which they will observe that, though Dr. MacDowall resorted repeatedly to Dieulafoy's pneumatic aspirator, and evacuated, not unsuccessfully, large quantities of pus, and this, indeed, with temporary relief to the patient, yet the disorganisation of the organ, as found after death, was such as to our minds to hopelessly preclude all chance of recovery on anatomical grounds.

I am, Sir, yours, &c.,

India, January, 1881. JOHN C. LUCAS.

Quercus.—1. Certainly not; a qualified medical man is at liberty to practise in any part of Her Majesty's dominions excepting any in regard to which he has contracted not to practise in.—2. There would be no propriety in their doing so.—3. There is nothing wrong in the titles. A young practitioner is apt to be impatient in commencing practice. His great aim should be to be in the way of duty, which comes when it is least expected, and to adhere to those great principles of ethics the observance of which distinguishes professional from ordinary commercial behaviour.

Cunctator.—We have no doubt the examination in question has been abolished, as all the regulations bearing upon it are omitted.

Clericus, M.A., has not enclosed his card.

A. Z. had better consult his usual medical attendant.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Byrom Bramwell, Edinburgh; Mr. Dodd, Rillington; Mr. Wright, Romford; Dr. E. L. Jacob, Epsom; Mr. Bryant, London; Dr. Mundie, Hessle; Mr. S. J. Rennie, Workington; Dr. Ward Cousins; Mr. Tegetmeier, London; Mr. E. J. Day, Dorchester; Mr. L. Tait, Birmingham; Mr. Judge, London; Dr. Lyster, Liverpool; Dr. Renner, London; Mr. H. Faulds, Tokiyo; Mr. Harding, London; Dr. Wise, Geneva; Mr. Evans, Bridport; Dr. Swift Walker, Hanley; Mr. W. J. Mickle, Bow; Mr. Weekes, Barcelona; Mr. S. Wilkinson, London; Mr. Digby; Mr. Ed. Jones, Sydenham; Mr. Shelley; Mr. Holderness, Windsor; Dr. Tripe, London; Dr. Macdonald, Cupar; Mr. Burdett; Mr. Jesse, Henbury; Mr. Shirtliff, Kingston-on-Thames; Mr. Haig, Torquay; Mr. Howe, Ripon; Mr. Lang, London; Messrs. Smith and Son, Dublin; Dr. Harries, Aberystwith; Mr. Ashmead, Brierley-hill; Mr. Porritt, Huddersfield; Mr. Smith, London; Dr. Silcock, London; Mr. Newman, London; Mr. Norris, South Petherton; Mr. J. Startin, London; Mr. Leuf; Mr. Sparrow, Middlesbrough; Messrs. Law and Son; Dr. Michael Taylor, Penryth; Dr. Barraclough, Dulwich; Mr. Wynter Blyth, London; Messrs. Leader and Sons, Sheffield; Messrs. Night and Garrard, Rotherham; Mr. Jackson, London; Surgeon-General J. K. Barnes, Washington; Surgeon-Major Melladen; C. H.; Beta; A Sanitary Engineer; Verax; F. P. S.; R. H. F.; The Registrar-General; A Family Doctor and Apothecary; L.S.A.; W. B.; A. B., Birmingham; Medico, Rhyl; &c., &c.

LETTERS, *each with enclosure*, are also acknowledged from—Mr. Adams, Marshfield; Messrs. Nuttall and Co., Burnley; Mr. A. Kerry, London; Mr. Hadstry, Cape of Good Hope; Mr. Harris, Wolverhampton; Mr. Birdwood, Gravesend; Mrs. Glendinning, Portsdown; Mr. Lyle, Durham; Mr. Hoare, Wansford; Mr. Gardner, Edinburgh; Mr. Wiley, Birmingham; Mrs. Boning, Cambridge; Dr. Law, St. Leonards; Messrs. NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

Croonian Lectures

ON THE

INFLUENCE OF THE CIRCULATION ON THE NERVOUS SYSTEM.

Delivered before the Royal College of Physicians of London,

By WALTER MOXON, M.D. Lond., F.R.C.P.

LECTURE I.—Part II.

But I am almost forgetting, in this digression, that I may be asked for some proof that the arrangements which I have described as a lock in the cerebral circulation actually lead to the obstruction and delay of the venous current which we are assuming they are designed for. Now, upon this question there is a very curious and interesting kind of evidence to show that throughout life the blood is held up at the mouths of the cerebral veins, and this evidence is in the so-called Pacchionian glands or bodies. If we look at this drawing of the venous system of the top of the brain in an elderly person, we see that around the points at which the veins enter the longitudinal sinus there are a number of knots of fibrous tissue, the nature of which has given rise to much inquiry and speculation from time to time. These bodies may be more or fewer in number, greater or smaller in size—may even be so large as to penetrate and even perforate the skull by their increase; but they are always there in subjects above three years old, and it is important to notice that they increase as age progresses, and are always attended by a thickened state of the pia-arachnoid membrane around the points where they take their rise in this membrane, and that they always appear about the endings of the great cerebral veins in the longitudinal sinus, and chiefly around the posterior cerebral veins. To understand the signification of these bodies and of the thickening of the membrane around them, we may reflect that the opposition of the currents in the sinus has the same effect as the meeting of the Thames with the waters of the Channel at the rising of the tide. The consequence in the case of the Thames or any tidal river is that a tide is felt for a certain distance up the river, and if it be high it floods the low-lying districts, ceasing to have any influence at a certain distance from the mouth of the river. In just the same way the quasi-tidal obstruction in the veins tells most near the mouth of the vein, and especially most on the feebler current at the side of the vein, which feebler current receives the latest small branches from the membrane, the obstruction damming up the last small branches entirely when it merely impedes the flow in the branches that feed the freer current in the middle of the vein. Now, a chronic delay in venous blood tends to cause increase and thickening of the lower forms of texture, such as fibrous tissue. Conspicuous examples both of thickening and of tuft-like growth may be seen on the capsules of the liver and spleen in heart disease and in cirrhosis. In some cases of very chronic and yet severe obstruction of the mitral valve I have seen the serous covering of the liver thickened and crowded with bodies which were exactly like in all points to the "Pacchionian glands." It was this observation, in fact, that suggested to me the explanation of the Pacchionian glands that I am giving, which is that around the mouths of the cerebral veins in the tidal area, if I may so call it, arise proofs of protracted delay of venous blood, in the form of thickening of the fibrous membrane and development of fibrous tufts, which are the Pacchionian glands, whose causation has long been a puzzle to observers. No such bodies are ever found about the points of exit of the veins at the base of the brain.

I will ask you now to direct your attention to the last particular of the anatomical part of my subject, and to consider the curious opening at the apex of the fourth ventricle, which forms the means of communication between the interior of the cerebral ventricles and the subarachnoid space of the spinal canal. It is through this opening that the cerebro-spinal fluid is driven or drawn to or from the cerebral ventricles by the action of the choroid plexuses, and thus a principal part of the escapement system of the cerebral circulation is put in operation. None of our works on anatomy bestow more than a trivial and passing notice on this opening. The edition of Quain's Anatomy that I learnt from spoke of the opening as "generally" present, and the last edition merely says on the authority of Magendie that there is such an opening. But surely throughout the entire frame, and amongst all the wonderful adaptations by which the liquids and solids of the body are actuated to their mutual duties, there is no spot more worthy of close attention than this curious aperture of escapement situated immediately above the very centre of life, and of essential service to that centre. Shall I be forgiven if I take time to describe the anatomy of the part with some care? It deserves the attention of the physiologist even if only because the sudden change of character of the surfaces which communicate at the opening is as remarkable as the difference of the surfaces which meet at the fimbriated opening of the Fallopian tubes. For the interior of the fourth ventricle is lined at the floor and sides with ependyma, or proper lining of cerebral ventricles, and this has upon its surface a layer of thick close-set epithelium, whose cells are of irregular cubical shape, and very conspicuous, whereas the subarachnoid space is entirely without lining membrane or epithelial covering. The change from the one character of surface to the other occurs very abruptly, the epithelial cells breaking into groups, and disappearing as you trace from the ventricle towards the space. The opening is in the middle line, and is another place of non-union of symmetrical parts. It is situated exactly over the spot where the central canal of the spinal cord joins the fourth ventricle. It is a hole with edges well-defined at the sides and below, but is entirely without any definiteness above; in fact, when you are proceeding from the subarachnoid space towards the fourth ventricle, upon the roof of the ventricle you find that there are no signs of a boundary at all. And, indeed, the matter is left curiously to chance, for in some subjects the choroid plexuses of the fourth ventricle wander out nearly an inch into the subarachnoid space in the most regardless manner, whilst in others they keep themselves well within the bounds that would correspond with the limits the opening reveals at the sides and floor of the ventricle. The line of demarcation between the subarachnoid space and the fourth ventricle is more than indefinite upon the roof of the ventricle; indeed, it does not exist. And the roof of the ventricle is, in fact, organised after the manner of subarachnoid space. This space runs forward on it to reach the valve of Vieussens. In other words, the subarachnoid space is in open continuity with the fourth ventricle all along the roof of the ventricle until you reach the valve of Vieussens, where a proper ependymal surface appears for the first time as you trace forwards.

The delimitation, then, between the fourth ventricle and subarachnoid space concerns only the sides and floor of the ventricle, and is entirely indefinite above. As to the sides of the ventricle, about this opening they are composed of a double membrane, the outer of which can be separated from the inner. Here is a drawing of the inner membrane after the outer has been removed. The outer membrane is the pia mater springing from the edge of the calamus scriptorius and reaching the under surface of the cerebellum, where it loses itself, or at least I always lost it. The inner membrane is a layer resembling the valve of Vieussens, but thinner. It is easily lacerable, like cerebral tissue, being composed of the felted fibrils of ependyma with a few nerve fibrils, and its inner surface is coated with the thick epithelium which I have described. It rises from the edge of the calamus scriptorius, and has pia mater at its outside, but separable from it, as I have said, and it rises up to reach the edge of the choroid plexus in the roof of the ventricle, beyond which it cannot be traced, except that it sends its epithelium over the ventricular face of the choroid plexus; not beyond this, however, so that it does not reach into the middle line of the roof. At the verge of the opening itself the pia mater extends in a fimbriated form one-twelfth of an inch or so beyond the free edge of the ependyma, and it is on this one-twelfth of an inch that the epithelium of the ependyma disappears as I have described.

I examined the opening in upwards of seventy brains removed with especial care for the purpose, and taken from subjects at different periods of life, some very early. Thus in a fœtus 2·6 inches long, which I took to be two months old, I found the three membranes—dura mater, arachnoid, and pia mater—quite distinct, and the opening of the fourth ventricle already evident, but its relations to the cerebellum and medulla oblongata not definite, on account of the undeveloped state of those parts. The choroid plexuses of the fourth ventricle were already very well developed. At yet earlier periods I found the thalami and corpora quadrigemina protuberant on the surface of the brain, uncovered by the cerebrum, so that the membranes which even here were distinct had no relations to these parts comparable to their relations in the developed brain. I observed though that the membranes of the brain develop very early. I have found a fringed opening of the fourth ventricle in the brains of dogs and of chickens. I could not succeed in frogs, the films of membrane were so thin, and I could not be sure of more than two membranes to the spinal cord of frogs.

At the fourth and fifth months of human fœtal life the opening is quite obvious, the lips of the orifice well formed; but the edges slope from below upwards and forwards, instead of upwards and backwards, as in the adult. This appears to prove that the backward growth of the cerebellum is greater than that of the pons and medulla after the fifth month, so that the upper attachment of the edge of the orifice to the cerebellum is moved back with the growth of the cerebellum. This backward growth of the cerebellum carries back the tail of the choroid plexus often far beyond the line of the edges of the opening; the choroid plexus seems thus stretched back in linear form to prevent its obstructing the opening.

I trust I may be pardoned this long account, because of the surprisingly slighting way in which the anatomy of this most vitally essential part of the human organisation is treated by anatomists. Not long ago a Guy's student was seriously reprehended by an examiner at the Royal College of Surgeons for speaking of a choroid plexus in the fourth ventricle. He was informed that he ought to know that the choroid plexuses are in the lateral ventricles.

Now considering that a large and free communication between the ventricles of the brain and the spinal canal through the end of the fourth ventricle is universal in all warm-blooded vertebrates, and is absolutely required in order to allow of variation in quantity of blood in the skull, and to adjust the pressure with which blood bears upon the brain; and considering that our security in changes of posture, and even in the less active matter of thinking, depends largely upon this communication, I cannot help suggesting that a little more notice should be taken of it, and a little more attention given to the facts concerning it. The admirably clear and instructive text-book of the Cambridge School of Physiology does not deign to touch the curious mechanism of the varying blood-supply to the human brain, although it treats very fully of the apparent intelligence with which a frog deprived of his cerebrum will scratch himself when tickled, and will seem to take care lest he should be upset when tilted about. Meantime I am not aware of any reasons to believe that consciousness and will must inhabit homologous parts of the brain in remote classes of vertebrates, or that light is thrown on the special functions of the human brain by experiments on frogs. When the head is inclined downwards, so as to be on a lower level than the trunk, and especially when anyone stands on his head, a sensation of great discomfort is produced, because the cerebro-spinal fluid, which is protective in natural postures, now reverses its operation, and forms a column of liquid of some length directly pressing into the ventricles of the brain, adding to the pressure which the blood produces by escaping with difficulty from the head, so that water as well as blood press forcibly upon the brain. I have never known anything more than discomfort occur from this cause, but it is well to remember the cerebro-spinal fluid, when in chloroform-syncope, &c., one is tempted to cause a flow of blood to the head by lowering it below the level of the body. For in so lowering the head you delay venous circulation, and send water as well as blood towards the brain, thus lessening the blood-changes there which you wish to increase.

To show how important it is that the opening in the fourth ventricle should be free let me shortly describe the case which first fixed my attention on the results of its absence or closure. A boy of sixteen had always been a rather slow, dull boy, forgetful and hesitative, without being at all idiotic or utterly incapable. He used to go to his father's warehouse, and amuse himself in his slow, dull way, without being of much use. This boy was one day not very well, but his illness appeared trivial. He stayed at home that day, and the next day went to bed early; he became worse in the night, being faint and weak, and a relative went to his bedside. Then quite unexpectedly, and rather suddenly, he died. I had not seen the lad during his life, but was asked to inspect the body. Nothing whatever of a morbid kind was found in the viscera of the trunk, but on raising the calvaria and removing the dura mater a very curious appearance offered itself. A large bladder, just like an hydatid, was in the right cerebral hemisphere, separating the convolutions from each other; it was about two inches in diameter. I naturally thought it was an hydatid, but on opening it I found it extended deeply into the brain, and, in short, it proved to be an immensely dilated lateral ventricle. The ventricle of the other side was almost as much dilated, but did not reach the surface. The post-mortem was made in a private house, and under the usual difficulties. I therefore took away the parts around and including the fourth ventricle. I hardened these, and examined them. There was a growth of papilloma—in fact, a wart—starting off the floor of the fourth ventricle near its apex, and running upwards to touch the roof, almost completely closing the opening of the ventricle and stopping the way of liquid out of it. The sudden death in this case and in several other cases of intra-ventricular dropsy of the brain which have come under my observation I believe to be due to inhibition of the heart through pressure upon the pneumogastric centres.

Having thus, at what I much fear will have seemed tedious length, described the mechanisms whereby variations in the quantity and in the pressure of blood within the cranium are provided for, I will now proceed to inquire whether these mechanisms are of due efficacy, and I hope to show that the provisions against undue pressure of blood within the cranium will be found so far efficient that wherever intra-cranial blood-pressure can be separated from asphyxia and strangulation, such pressure does not produce any ill result. In other words, congestion of the brain as distinguished from strangulation does not produce symptoms, and those symptoms which are supposed to be due to congestion of the brain as a distinct disease must be referred to other causes. But before beginning the course of my argument, may I make clear the position intended to be taken up. I wish to contribute towards doing away with a fallacious notion which continues from one author to another as work succeeds work on Practical Medicine—the fallacious notion that a quantity of blood forced into the vessels of the brain becomes itself the cause of several serious and even fatal diseases, which are described under the name of "congestion of the brain," or "determination of blood to the head." Whereas in such cases there is no mechanical obstruction to exit of venous blood from the cranium. I wish to show that no quantity of blood that can be forced into the vessels of a brain whose veins are not closed by obvious pressure, does as a matter of fact produce any such symptoms. I believe this may be proved beyond dispute. I should like to make it clear that in doing this I am proceeding in harmony with the great principles enunciated by the greatest of pathologists—the illustrious Professor Virchow—who, with vast learning and keen original observation, showed that we are not to look to the vessels for the initiative in diseases of the textures of the body. He proved that the life of texture is in the texture itself, its pathological as well as its natural life, and that the movements of the blood in what is called irritative or inflammatory congestion are secondary to a demand upon the blood and bloodvessels, which demand is made by the proper power of the texture elements. And these elements have power to grow and to multiply, and to exert themselves in function, dependent on the blood only as the labourer is dependent for his powers on his bread and cheese. And when I say that the forcing of blood into the vessels of the brain produces no symptoms, I do not mean that no symptoms will attend a fulness of the vessels when that fulness has been caused by disturbance of the brain's texture itself. There will be symptoms, but symptoms caused in the texture by the very irritation that drew the blood to the brain, and not to be ascribed to the blood that is drawn thither.

There is one power by which blood can be sent into the vessels of the brain with certainty, and with any degree of force that may be desired, and that power is atmospheric pressure. It needs no experiment to show that great increase of atmospheric pressure must drive the blood away from the surface of the body and into any parts that are accessible to blood and not to air; such parts are the interior of the cranium and spinal canal. Even moderate degrees of pressure, such as an addition of half or three-quarters of an atmosphere have been noticed by Petrequin and Sandahl to cause the disappearance of a tolerably considerable hyperæmia of the conjunctiva, but such minor degrees of pressure have had no ill results upon the nervous system, although such results have been carefully watched for in air-chambers constructed for the relief of asthmatic persons. The result, as given by Sandahl, who carried out observations on an extended scale, is thus described :—"Upon the nervous system the pressure served to exert a directly soothing effect, whereas on sudden reduction of the pressure nervous phenomena made their appearance." The only marked consequence of the pressure was slowing of the pulse. But in fulfilling some of the demands of civilisation, and especially in the construction of bridges over great rivers, workmen have had to go to great depths below the surface of the water. And the human frame in some instances has been exposed to degrees of pressure vastly greater than any that could be applied in the therapeutic air-chamber. The effects produced by such great degrees of atmospheric pressure have been recorded by many observers in numerous memoirs, one of the best of which is in the *Annales de Chimie et de Physique* for 1841, by M. Triger, who worked at a depth of sixty feet in the valley of the Loire ; but the greatest depth which I can find to have been reached was upwards of ninety feet, in the construction of the great bridge across the Mississippi at St. Louis. A good account of the effects of the tremendous power exerted at this great depth was published by the chief engineer, Captain Eads, and is printed in the *Medical Times and Gazette* for 1871. Like all who have witnessed and experienced the effects of such pressure, Captain Eads dwells long on the severe pain in the ears which is caused by the force acting upon the tympanic membrane until air enters by the Eustachian tubes into the tympanic cavity. No other result is noticed until the Captain speaks as follows :—"When the depth of sixty feet had been attained, some few of the workmen were affected by a muscular paralysis of the lower limbs. This was rarely accompanied with pains, and generally passed off in the course of a day or two. As the penetration of the pier progressed the paralysis became more difficult to subdue, and in some cases the arms were involved, and in a few cases the sphincter muscles of the bowels. The patients also suffered much pain in the joints when the symptoms were severe, an average of at least nine out of ten of those affected suffered no pain whatever, but soon recovered, and generally returned to the work. . . . . The total number of men employed in the air-chamber of this pier was 352 ; of this number about thirty were seriously affected. . . . . Twelve of the cases proved fatal. . . . . Nearly, or quite, all of these deaths happened to men unaccustomed to the work. Several died who had worked but one watch of two hours. . . . . In contrast to this is the fact that a very large number of the men (certainly one-half of those constantly employed) commenced with the work at its inception and remained throughout its continuance entirely without injury or inconvenience. . . . . Considering that the air-chamber was briefly visited by thousands of persons, including many delicate ladies, even after it had reached the bed-rock, some remaining as long as an hour in it, without any of them experiencing the slightest ill effect from the pressure, and that no cases of any importance whatever occurred amongst the workmen after the watches were reduced to one hour," Captain Eads feels satisfied that this is the true cause of the paralysis, and that by lessening still more the duration of the watches a depth considerably greater can be reached without injury to the workmen. Too long a continuance in the air-chamber was almost invariably followed by symptoms of exhaustion and paralysis.

It is necessary to note that all the accounts of this extreme pressure agree in showing that no ill results appeared during its continuance, and that the grave and sometimes fatal symptoms which occurred on its removal affected the lumbar portion of the spinal cord, producing paraplegia, which would not correspond to lesion of the brain. In fact, the brain showed a strange immunity from injury under this great pressure.

My next step will be to endeavour to estimate the extent to which blood is forced into the brain during exposure to the atmosphere of the caissons, that I may compare this forcing of blood into the brain with such stress of blood as the intrinsic powers of the circulation are able to exert upon the brain. For this purpose we will reflect as follows :—Each act of ordinary breathing exerts a force of about 42 mm. of mercury. Now, the effect of each breath is to increase the arterial pressure to a degree equal to at least twice the pressure caused by one beat of the heart. But when the body is exposed to atmospheric pressure of 42 mm. of mercury blood is driven into the closed cavity of the skull with as great force as air drives blood into the chest in ordinary breathing. So that within the cranium there would be for each 42 mm. a rise of pressure as great as that expressed by two beats of the heart (really more, because the pressure in the carotid, which I have taken as the standard of comparison, is the whole pressure within the chest, lessened by the direct pressure on the arterial blood). But the pressure at 90 ft. depth of water is about fifty times 42 mm. of mercury, so that the intra-cranial pressure produced in the caissons is as great as that of 100 heart's beats.

Now, if we observe an inhibition trace to see how many heart's beats restore the normal tension after it has been brought down by inhibition to the line of no tension, we see that about ten heart's beats suffice to bring up the full normal tension. And the atmospheric pressure of the caissons was equivalent to 100 heart's beats, so that the caisson pressure would raise normal arterial tension ten times. But as to the highest morbid arterial tension observed with the sphygmograph, Drs. Burdon-Sanderson and Galabin, kindly answering my inquiry, say that 9 oz. to 10½ oz. make the highest morbid tension they have recorded, which is about three times the normal tension as observed with the sphygmograph. But the caisson tension is ten times the normal, and hence is three times the greatest abnormal tension from intrinsic causes. So far as this comparison is valid, the general conclusion is that the caisson pressure raises the whole vascular tension within the cranium by an amount which is as great as three times the greatest morbid arterial tension that has been observed to be due to the intrinsic powers of the circulation.

I dwell upon this kind of congestion of the brain because the flow of blood to and from the brain is meantime free, and this congestion is one purely due to fulness of the vessels, so that we have an active congestion of the brain affecting only the condition of the circulation, and not starting in any variation of behaviour in the nervous tissue. In this example we can consider the effects of pressure within the vessels apart from the condition of strangulation, which condition has had a very detrimental effect, as lending a seeming support to assumptions of independent congestion of the brain. And I have thus endeavoured to show that the pressure to which Captain Eads' workmen were exposed must have the effect of filling the vessels of the brain with a current of blood under greater stress than would be possible through any action of the intrinsic forces of the circulation whilst normal entry and exit of blood from the brain was allowed. Whether the comparison of pressures I have made is valid or not, I am aware that there are questions regarding the respiration curve in the manometer tracing which are unsettled. It still remains true that the effects on removal of the pressure are so peculiar and terrible as to show how great is the degree of stress from which these symptoms form the recoil. It is evident that the physical conditions of the circulation in the nervous centres upon removal of great atmospheric pressure are unknown and probably very complicated ; and I will not attempt to speculate upon the question of their nature, but only ask you, first, to observe that whatever may be the cause or causes of them, they affected only the lower end of the spinal cord ; and, second, to observe that the tremendous positive pressure into the vessels of the brain did not produce upon it any effects whatever. Under the positive pressure there were no effects, and under the unknown conditions arising through sudden relief from pressure, the tip of the spinal cord was the part which showed itself to be suffering.

I will ask you to remember the negative effects of the great pressure of blood into the brain for the argument of my next lecture, and now will digress for the remainder of this lecture, to inquire why the after-effects of atmospheric pressure should involve only the lower part of the spinal cord. And then I will point to some inferences from my explanation which may have a bearing on obscure points in clinical medicine. Here I must take the liberty of drawing your attention to some very well-known anatomical points by which the curious fact that only the legs suffer in the caisson disease is, I think, quite clearly explained. I need scarcely remind you that whilst the spinal canal extends down into the sacrum, the spinal cord does not extend below the lower border of the first lumbar vertebra; but the spinal cord gives off nerves all the way down on each side, and the spinal canal on its part is pierced on each side with a series of openings all the way down, even to the lowest part of it, at pretty even intervals, the openings serving to let out the nerves that arise from the cord. The consequence of this arrangement is of course that the distance between the place of origin of the nerves of the cord, and their place of exit from the canal is short, as to the upper nerves, but increases much as to the lower nerves, so that the nerves run nearly horizontally to the neck and upper limbs, whereas to the loins and legs they run a long way down before reaching the dura mater, extending indeed for many inches, and forming a bunch of long, loose threads, something like a horse's tail, and known as the cauda equina. Now, the spinal cord is suspended within the spinal canal in subarachnoid fluid, which entirely insulates it. And meantime surrounded by this liquid, and insulated by it, the spinal cord itself is out of reach of any blood-supply except such as can come to it from the brain above or else along the nerve-roots at the sides. And in fact the supply of this important part becomes, if I may so speak, one of Nature's difficulties. Let us see how the difficulty is met. The blood-supply to the spinal cord is carried out by slender vessels which come from the vertebral arteries within the cranium. There are three of these arteries—one on the front and two on the back of the cord; they are very slender, and yet have to run along its whole length. No arteries so small as these run so great a length elsewhere in the body, and pressure falls rapidly in minute arteries as the length of pipe increases, so that it becomes necessary to reinforce these slender vessels wherever possible; and advantage is taken of the nerve-roots to send up little reinforcing arteries along these. In the part of the cord corresponding to the neck, upper extremities, and trunk, where the nerve-roots are short, the reinforcing arteries are also short, and they reach and join and furnish blood to the spinal arteries—so that in this part of the cord every segment of it is supplied with blood from two directions, the anterior spinal artery bringing blood from above and the reinforcing artery from below. But when you approach the tip of the cord the supply from below becomes exceedingly precarious, and even apt to fail entirely, because upon the long strands of the cauda equina the small arteries are too narrow and too long to reinforce the cord with any certainty. But at the same time the supply from above has to be furnished with greater difficulty than in the upper regions of the cord, because the original anterior spinal artery is very far away, and the reinforcing arteries even in the lumbar region have to run considerably longer courses than they had in the cervical region.

Thus the tip of the cord has its blood-supply only from above, and deficiently even there, whilst the upper parts of the cord have a better sustained supply both from above and below; and this becomes especially the case upon the cauda equina itself, for here the arteries are exceedingly minute and uncertain in size on the several nerves. Hence we see that the tip of the spinal cord corresponding to the lower limbs and sphincters is much more weakly organised as to its circulation than are the upper parts of the cord. But lest this should seem a purely theoretical view, let me quote a report which Dr. Carrington, the able Demonstrator of Anatomy at Guy's Hospital, has kindly sent me after examining this matter for me. Dr. Carrington says:—

"I have examined seven cords in all, and send you the results. I have also written out the account of two which were the best of my specimens in a little more detail, and I can send you a like account of all if you wish it. 1. Our subjects are injected from the femoral artery; therefore, *à priori*, there would be a greater probability of the lower than of the upper end being well injected. The fact that it was not the case makes the results more striking. 2. In all the cords there was clear evidence that the anterior spinal artery filled from above downwards, the injection ceasing either at the lower end of the cord or above that part. It was obviously reinforced by vessels which entered along the nerves. 3. In no case were the reinforcing vessels on the nerves of the cauda equina injected.

"*Details.*—Case 1. Anterior spinal artery injected in upper third, injection ceased at junction with middle third; the injected part was reinforced by branches which ran along the nerves of the upper third; none of the reinforcing branches were injected in the lower two-thirds on the anterior surface. On the posterior surface the arteries which accompanied the nerves were more or less injected as far as about two inches from the commencement of the filum terminale, many were, however, uninjected. No injected arteries accompanied the nerves of the cauda equina.—Case 2. Anterior spinal artery particularly well injected as far as the beginning of the filum terminale. Beyond this point the vessel could be traced empty on the filum. The injected part of the vessel was well reinforced by vessels which ran on the nerves. On the posterior surface the arteries along the nerves were injected with varying degrees of fulness; some were uninjected as far as two inches from the end of the cord, at which point the injection ceased. The largest and lowest of these reinforcing arteries accompanied a nerve which ran for a distance of one inch within the dura mater. No injected arteries were found with any of the nerves of the cauda equina, but, *per contra*, on one of them a well marked long slender artery was found empty."

We have here convincing proof that under difficulties of circulation, such as must arise when the body is subjected to great changes of atmospheric pressure, the tip of the spinal cord is a part which would suffer from anæmia, for it is out of reach, except by vessels of great length, in proportion to their calibre. Meantime the career of these vessels is through the cerebro-spinal fluid, which forms an easy water-bed for them that may favour the freedom of flow in their minute channels. But then, unfortunately, this cerebro-spinal fluid is itself subject to variations of pressure. Indeed, it exists as a means of conveying pressure from the cranium to the spine, and we have seen that, when there is activity of circulation within the skull, the cerebro-spinal fluid is sent out to press a little, hardly within the spinal canal, on these smaller arteries of the spinal cord. So that over-much activity of the cerebral circulation would tend to compress these arteries, and interfere with the straight and narrow economy of the unfortunate end of the spinal cord. I think this is why very studious people get so delicate about the caudal ends of their spinal cords. And it is, at any rate, a good reason why students should take care to let their legs have a fair share of activity in every day's time for the establishment of proper circulation in the spinal centres. Now, whilst the tremendous pressure in the caissons is sending blood into the vessels of their brains and cords with great force the workmen feel more lively and elastic, and go up their ladders with ease. But as soon as this tremendous pressure is taken off, and the vessels of the nervous centres, instead of being intensely stuffed with blood, have a tendency to lose their contents in the same way as they do when exposed to a rarefied atmosphere; so that a general deficiency of supply arises in the previously well-filled channels. This difficulty tells most on the more weakly organised system of supply to the spinal cord, and hence the workmen are paralysed as to their lower extremities and sphincters when they go into the air.

But how, then, should any people escape? Have I not proved too much? As to this question I have observed that the anastomotic reinforcing branches of artery along the nerves vary in size upon the several nerve-roots in different subjects, and a large anastomotic branch in the dorsal region would do much to save the cord. Also it is true that the vascular tension is more efficient in some people than others. And as a matter of fact we can directly observe that some peoples' textures bear variations of blood-supply much less equably than do the textures of other people. Further, I think it probable that when the arterial supply of the cord fails under the caisson pressure the result is paralysis, but when the result of the pressure tells more on the veins—keeping them too full—the result is that pains in the limbs are complained of. But when I thus am indicating this peculiar source of weakness in the spinal cord at its lower end, it will naturally be asked whether there is any further proof of such a weakness of this part—whether the cord is paralysed under other conditions very trying to its peculiar circulation. Well, the answer to this question is not far to seek, seeing it is an otherwise and I may say a hitherto unexplained fact that in so many cases of spinal palsy from whatsoever cause the lower limbs suffer, while the upper limbs escape; whereas, so far from the lower limbs being intrinsically weaker, it is of course true that in cerebral paralysis the lower limbs suffer less and the upper limbs suffer more. Let us take the example of common paraplegia. Everybody knows that this nearly never attacks the upper limbs, but it affects the lower extremity and lower part of the trunk, and a short experience of cases of this disease will show a remarkable uniformity in the extent to which the lower half of the body is involved. You will find almost always that the paralytic affection in common paraplegia ceases to give evidence of its presence about the lower dorsal or upper lumbar region. Numbness and paralysis are not traceable above the lower margins of the thorax, ceasing often along a rather well-defined line. The anatomical state of the substance of the cord found post-mortem to account for this is a condition of "softening"—i.e., a pathological state which is the same as that found in the brain as a consequence of impairment of nutrition by deficiency of the supply of blood. The causes of this condition are often obscure, but are in many cases evidently debilitating causes, such as in this very typical case which I met with. An Irish dock-labourer had been standing about the entrance of the docks for some days without employment, and getting little food, when he felt pins and needles run up and down his legs; and after he got home that evening he felt very weak, and went to bed. In the night, being taken with diarrhœa, he went from his bed, feeling very cold and feeble, and he could not return, being totally unable to move his legs. This man lived about a year, his disease showing all the characters of common paraplegia, and post-mortem examination showed the lumbar cord in a state of "white softening." This was one of my cases when I was clinical clerk, and it puzzled me much to know why the poor man should thus suddenly suffer from so chronic a change as white softening, and why he should only have symptoms just up to the top of the lumbar cord, and never higher in the whole course of his ailment; but I seem to know well now why it was. He was paralysed through starvation of his cord on account of the difficulties of supply to it, and the paraplegia did not extend above the lumbar cord, because the cauda equina does not extend above it, and the upper dorsal part of the cord obtained enough blood along short arteries through which the blood pressure had been able to force a sufficient supply. Indeed, the very different kinds of cause which agree in producing paralysis of the lower extremities would show that there must be some such simple and general explanation of its ready occurrence. An instance came under my observation so like that of my poor dock labourer that the similarity of effect was as remarkable as the unlikeness of causation. It was in the person of a very well-fed and healthy female cat which suffered, I am sorry to say, at my hands. A nest of thrushes was eaten by cats in my garden, and I thought it fair to retaliate by putting down a bowl of milk also containing prussic acid, and I warned a relative to keep her cat in; but, to my grief, next morning the only cat in trouble was my relative's fine cat, which lay beside the bowl of poison in a curious state, quite paralysed as to the hind legs, but otherwise unaffected. The front paws were active and vigorous, so that she could pull herself about on the level ground by means of them, but the hind legs did not make any movements for three weeks. I did what I could for her, but it was four weeks before the cat could leave the basket she was placed in, and six months elapsed before she could spring upon a wall; after this she quite recovered, and had several large families. Now, prussic acid acts by lowering the tension of the blood after a slight temporary rise, and whereas it is very difficult to suppose that the prussic acid had any preferential power over the nervous centres of one pair of legs as compared with those of the other pair, it is, I think, quite readily to be accepted that as the hinder pair draw blood through longer and very slender pipes of vessel, the cat, lying with depressed circulation nearly dead all night, suffered so much in the nutrition of the end of her spinal cord that it became almost irrecoverable. Indeed, it is interesting to observe how the very temporary action of the poison should have so damaged the cord that it was six months in recovering, whilst the damage was so adjusted that recovery was finally possible. Such an occurrence throws some light upon the curiously protracted tenacity of injury on the part of the cord, which the history of paraplegia brings so painfully forward. But it is not only prussic acid that affects the hind legs of creatures more than their fore legs. Although toxicologists have paid no attention to the difficulties of circulation in the lower end of the cord, so that no experiments have been made with the intention of developing this point, yet in reading through a book on Materia Medica one finds repeated examples of drugs which are depressants of the circulation, and which paralyse the hind legs of animals without affecting their fore legs. Among these I mention aconitia, conia, and, doubtfully, veratria and chloral. With reference to prussic acid, it is said to benumb the hind legs first.

Again, for other instances, take the very complete paraplegia of the lower extremities which so much impressed Dr. Bristowe in the highly interesting cases of Rupture of Abdominal Aneurism, which he recently published. Surely, if we consider the mode in which the arterial supply of the spinal cord would be reduced by the bursting of the aneurisms, the paraplegia in these cases is immediately comprehensible. Again, if we take the so-called urinary paraplegia, of functional paraplegia of any kind, including what is called hysterical paraplegia, we find these affections never troubling the upper limbs, but always the lower. And I think the point I have raised will suggest lines of investigation that may throw great light on this obscure class of nervous diseases. I believe that it is by impediment to the exceedingly and peculiarly difficult blood-supply of the caudal end of the spinal cord that all these various conditions lead to paralytic weakness of the lower limbs, and they are to be met by conditions improving the circulation if possible. Why the lumbar cord should be thus straitly supplied is an interesting question. Perhaps it may be connected with a necessity that the economy should be so organised as to feel fatigue early enough in the parts which directly put forth exhausting exertion, lest strain of effort should first overtake more vital parts that secondarily share in all such exertion. In short, the cord is supplied scantily, so that we should sit down when we have walked enough, and lie down when we are tired, and especially that we should, if necessary, fall down when faintness overtakes us, to the end that in the horizontal position the circulation may be able to restore itself.

Gulstonian Lectures
ON
ANÆMIA.

Delivered before the Royal College of Physicians,

BY SIDNEY COUPLAND, M.D., F.R.C.P.,
PHYSICIAN TO THE MIDDLESEX HOSPITAL.

LECTURE II.—PART I.

Idiopathic Anæmia: Earliest Recognition of it by Addison—Records of Cases (1851–1871) by Barclay, Lebert, Wilks, Habershon, King—Gusserow—Biermer's New Departure (1871)—Growth of its Literature in the last Decade—Wide Extension given to the Term "Pernicious"—Clinical Features of "Pernicious" Anæmia—Onset—Progress—Digestive, Circulatory, and Nervous Symptoms—Hæmorrhage—Irregular Pyrexia—Duration—Termination in Recovery—In Recovery followed by Relapse—In Death—Post-mortem Appearances.

MR. PRESIDENT AND GENTLEMEN,—It is impossible to speak of idiopathic anæmia without reference to Addison, for he it was who seems to have distinctly called attention to a class of cases in which anæmia is the prevailing symptom from first to last—an anæmia not depending upon recognised causes, not associated with wasting of the tissues, but insidious in its onset and slowly downward in its progress, revealing after death no changes but those of fatty degeneration, especially of the heart. The passage in which he summed up his experience of this condition occurs early in his essay on Disease of the Suprarenal Capsules.[1] This passage has been so often quoted that it is hardly necessary for me to repeat it now, much as I am tempted to do so, for it is a model of a succinct summary of clinical observation. It was written in 1855, but Addison's observations dated far before that period, and indeed he described the condition in his lectures as early as 1843.[2] There is no doubt also that similar cases had been observed, and a few recorded about the same period. In 1851 Dr. Barclay published the notes of two fatal cases of anæmia[3] occurring in St. George's Hospital. One was the case of a man aged thirty-four, admitted under Dr. Page on Jan. 21st, 1852. He had been ailing for twelve months, and had suffered from inconstant aching pain in the loins, accompanied by scanty, loaded urine. He had lately lost flesh and had a slight cough, was remarkably pallid, complained of shortness of breath and palpitation; pulse 120, and very weak; and he suffered from constipation. There was deficient breath-sound at both apices, especially the right, where it was distant and tubular; there was then no cardiac murmur. A fortnight later he was attacked by vomiting. A bellows-murmur with the systole developed, best heard in the mid-præcordia and towards the apex. He rather rapidly passed into a state of exhaustion, ending in coma, on Feb. 11th. Mr. P. Hewett, who made the autopsy, found the body well nourished, the brain very anæmic, a few extravasations in the pia mater, cretified deposits at the apex of the right lung, emphysema elsewhere, the posterior parts being engorged with frothy serum. The heart was healthy and pale, but contained large fibrinous clots in all its cavities. The abdominal viscera were bloodless, and a few cysts were observed in the left kidney. The dark and healthy colour of the muscles was observed in contrast with the pallor of the integument, and the extremely yellow colour of the subcutaneous fat was also noted. The other case was that of a married woman with several children, admitted under Dr. Wilson, Jan. 29th, 1851. She had not been well since her last confinement, four months before; had been weak, but had not suffered from hæmorrhage; she had, however, been troubled with diarrhœa for two months previously. She was extremely anæmic; pulse quick, feeble, and empty; appetite bad; urine scanty and loaded; her only complaint was of general weakness. The diarrhœa was checked by remedies, but she did not gain strength. She suffered from insomnia, and had some attacks of dyspnœa, after one of which she died, about three weeks after admission. The post-mortem examination by Dr. Ogle revealed the pallor and slightly yellowish tint of skin, slight œdema of the lower extremities, great pallor of abdominal walls, fatty kidneys, frothy serum in the lungs, some ecchymoses in the larynx, a healthy heart containing little or no coagulum, but a small quantity of semi-fluid blood.

---

[1] See Addison's Collected Works (New Sydenham Society), p. 212. The passage is quoted by Dr. Pye-Smith in Virchow's Archiv, vol. lxv., p. 507; by Dr. S. Mackenzie, THE LANCET, 1878, vol. ii., p. 799; by Dr. Finny, Brit. Med. Jour., 1880, vol. i., p. 5; and many others.

Lebert, too, in 1853 had recorded cases of fatal "puerperal chlorosis" at Zurich—the seat of the subsequent observations of Gusserow and Biermer—and had spoken of these as examples of what he regarded as an "essential anæmia." Then, however, a long silence on the subject occurs in medical literature, broken only by the publication in Guy's Hospital Reports for 1857 of a series of cases by Dr. Wilks, under the head of "Idiopathic Fatty Degeneration," and of a case in THE LANCET for 1863,[4] by Dr. Habershon in a paper on this subject. The patient in this case was a spare woman aged forty, who had for many years been subject to attacks of vomiting, which for eight months before her admission had been almost of daily occurrence. She had much gastralgia, pain in the back and limbs, and was very pallid. The attacks of pain were renewed with much severity. She, however, improved, and left the hospital, to return a year later, "blanched, emaciated, and extremely feeble." No gastric disturbance was present now, only an extreme degree of asthenia and anæmia, under which she sank in two months. The necropsy by Dr. Wilks disclosed only intense anæmia of organs, marked fatty degeneration of the heart, and slight, passive effusions in the serous sacs. Thus, these observations showed that in the hospital of Addison, at any rate, the existence of the disease was recognised; and Dr. F. Taylor did good service in collecting all the cases observed there up to the year 1878—namely, as many as twenty-three.

Curious to learn whether the like experience had befallen the physicians of the Middlesex Hospital, I have searched the post-mortem records for any fatal cases which could be thought to have belonged to this class, and from 1844 to 1871 (excluding 1852 and part of 1851) I can find only one unequivocal case, which, it will be seen, was associated with a certain amount of gastric disease. This case occurred in 1865, its subject being a woman aged fifty-one, who was admitted for extreme anæmia three days before her death. No satisfactory history could be obtained, save that she had become rather rapidly anæmic. The skin was of a peculiar yellow hue, and she suffered from constant vomiting during her brief stay in hospital. After death the sallowness of the surface was noted, also a considerable layer of subcutaneous fat. There was effusion in the serous sacs, and œdema of the lungs. The heart was of normal size, contained a little fluid blood—no coagula, but the condition of its walls is not recorded. There was slight atheroma of the aorta. The spleen was small and normal; the kidneys small, and the seat of a few minute cysts. The gastric mucous membrane was thickened in the pyloric region and the seat of a small polypus. Recent hæmorrhage had occurred under the dura mater, and the brain was bloodless. Of other cases which come less clearly under this category I find one in 1844, of a woman, complicated by old pulmonary tubercle and recent pneumonic hepatisation; one of a boy aged eight, in 1857, thin and sallow, with slight serous effusions, ecchymoses in the heart, which is described as "yellowish, mottled, and very fatty," the liver of a deep yellow-brown colour, with bleeding points and white specks on the surface; and one in the same year of a man aged thirty-five, who died suddenly of fatty heart. These practically comprise all the cases within the period mentioned, with evidences after death of extreme anæmia and cardiac degeneration; other cases being chiefly those of cancer, renal disease, and purpura, one or two of which latter might possibly belong to the class in question. In 1871, however, an undoubted case occurred under Dr. Greenhow's care, and was published by my friend and former colleague, Dr. R. King, then medical registrar. I shall give the details of this case subsequently, but mention it now because its publication, antedated by a few weeks the appearance of an essay by Biermer, which did more than anything else to draw general attention to the subject.

Biermer's work must be taken in connexion with that of Gusserow (for both laboured in the same field), who in 1871 published six cases of a fatal form of anæmia in pregnant women. Biermer, who had previously related a case before a society at Dresden in 1868, described and summarised in the essay referred to fifteen cases of a "peculiar form of progressive pernicious anæmia, usually accompanied by fatty degeneration of the circulatory passages, and, secondarily, by hæmorrhages of the skin, retina, brain, and its serous membranes." This publication marked a distinct departure in the knowledge of this disease, and its taking and rather startling title assisted to draw attention to it. From that time to this, just ten years, a whole literature has sprung up around the subject.[5] For a time it was even thought that in this "progressive pernicious anæmia" of Biermer a new disease had been discovered, but Drs. Wilks, Taylor, and Pye-Smith reasserted the claims of Addison, and proved conclusively that no new discovery had been launched upon the world. Nor has the new nomenclature been without its drawbacks. It designates more than is implied by the term "idiopathic," much as we may wish to banish that term from nosology, and it has rather obscured than emphasised that leading fact of the condition described by Addison. For by the use of this terminology authors have been led to class together cases of anæmia depending on known causes with those truly "idiopathic," and some even speak of the supervention of pernicious anæmia in cases of cancer, for example. I shall show that this extension is perhaps justifiable provided that at the same time a distinction be made between the cases which arise spontaneously and those where the anæmia is obviously secondary. At present I will merely state my belief that pernicious anæmia includes, but does not comprise, idiopathic anæmia.

I have collected 110 cases, including most of those mentioned by M. Lépine in a review published in 1877. The number might, I believe, well be doubled, before embracing all those cases which have been recorded. Seldom has such a mass of evidence bearing on any one disease been accumulated in so short a time; and yet it is not possible to arrive at a satisfactory solution of the question of its origin. It presents us, however, with the symptomatology of anæmia in its most severe form, and throws light upon the most marked lesion produced by anæmia. Of these 110 cases, 56 were males and 54 females. The ages at which the patients came under notice—often, that is, only a short time before death—varied with the sexes, for among the male cases the majority—viz, 33 or 59 per cent., occurred between the ages of forty and sixty; and among the female series—34 or 63 per cent.—between twenty and forty.

The preponderance of females corresponding to the period of child-bearing.

The onset of this severe affection is sometimes quite sudden—in such cases following severe mental shock or some violent emotion; or a profuse hæmorrhage, which at the time may threaten life, leaves behind it an anæmia which never disappears, and may become pernicious—i.e., may deepen in intensity in spite of treatment. More commonly this exciting cause is added to a pre-existing and long-standing anæmia, which then takes on a fatal form, or the determining event may occur in some other exhausting discharge. Leaving for the present the consideration of these prodromal influences, I may simply state now that in many cases the onset is gradual and insidious, having perhaps in some cases a foundation in conditions of blood impoverishment, but in others arising quite apart from such conditions. Or the patient may have been always below the standard of health as regards blood; may have suffered more than once from extreme anæmia, and have regained the previous level, to be finally again lowered beyond restoration. However this may be, the symptoms which usher in the condition can all be attributed to it. There is a growing pallor of the skin and visible mucous membranes: a pallor frequently mingled with a yellowish tint, and even with a slight degree of actual jaundice; and the face becomes wax-like in appearance. At the same time there is an increasing disinclination for physical exertion, partly from mere listlessness, partly from the breathlessness and palpitation which any physical effort evokes. The nutrition of the body is often well preserved; there may be, as Addison remarked, even an excessive amount of cutaneous fat. Then, as the blood becomes more impoverished, dropsical effusions may appear in the eyelids and lower limbs; but such œdema is not a constant symptom, and is generally late in its appearance. With the muscular asthenia there is often complaint of pain in the limbs or back; and headaches, vertigo, and tinnitus are frequent. Sleep is sometimes, but not usually, heavy, a lethargic, drowsy state supervening towards the end, which may pass into semi-coma. But insomnia is a more constant symptom. Delirium may occur at the close, and sometimes convulsions. On the side of the digestive system there is generally loss of appetite, it may be with actual intolerance of food, and dyspepsia with nausea and vomiting are common. Indeed, vomiting stands out prominently among the symptoms of the disease, so common, so frequent, and so early in its occurrence as to lend support to the view of Drs. Flint and Fenwick as to the essential dependence of obscure and fatal anæmia upon primary gastric derangement. Although in some cases such vomiting and other symptoms of gastro-intestinal disturbance do precede the appearance of the weakness and pallor, yet it is not always so. Thirst, too, is marked in many cases. Gastralgia and epigastric tenderness are generally associated with the dyspeptic symptoms. Then, as to the intestines, diarrhœa is almost as often met with as vomiting, occurring sometimes early in the disease, sometimes just towards the close, which it determines; and although it is amenable to treatment it may recur again and again with much severity. Constipation is not so common as diarrhœa.

As a rule, in the earlier stages, the breathing is quiet, except on exertion, which induces marked breathlessness; but sometimes, at an advanced stage, attacks of dyspnœa are frequent and painful, and may lead to a fatal result. In the cases I have had the opportunity of reading I have not found this dyspnœa recorded as being of the peculiar ascending and descending rhythm, with a period of apnœa, known as Cheyne-Stokes respiration. The association of that type of respiration with fatty degeneration of the heart was noticed by its discoverers, and though it occurs under other conditions also—e. g., uræmia, cerebral hæmorrhage, embolism, &c.—yet its association with fatty heart is still accepted. As such degeneration is the most constant morbid lesion of anæmia, it is at least singular (if it be a fact) that this type of dyspnœa does not occur. As a rule, unless there be old disease in the lungs, there are no abnormal physical signs, except towards the end of life, when these organs become engorged, and serous effusions may take place in the pleura.

Attacks of syncope are liable to occur, but do not seem to be so frequent as might be imagined. The action of the heart is generally regular and quick, often very feeble. The impulse is often widely visible, undulating, and thrilling; the area of præcordial dulness laterally increased, signs attributed by some to retraction of the lung, by others to dilatation of the heart itself. The so-called "hæmic" bruits are commonly, but not invariably, met with; a systolic blowing murmur at the apex and xiphoid cartilage, a bruit of coarser character simulating pericarditic friction at the base. The large arteries of the neck often visibly pulsate, and are the seat of loud murmurs. The jugular hum is seldom absent, and pulsation of the jugular vein is often observed. The pulse is soft and compressible, quick, jerking, and empty.

In all these symptoms there is nothing peculiar or special. They simply denote the presence of an anæmia of pronounced degree, but there is one group of symptoms which occurs with such frequency in those severe forms as to be almost regarded as distinctive of them. I refer to the supervention of hæmorrhages, and here it seems to me important to make some reservations. In several cases hæmorrhages of one kind or another—e.g., epistaxis, menorrhagia, take place in the prodromal period, and antedate the development of the anæmia, which they have much share in producing. Such hæmorrhages must be distinguished from others, often quite as profuse, which follow upon the appearance of the anæmia, and when appearing they add greatly to the intensity of the disease. In a case the particulars of which I shall presently narrate the patient had been anæmic, and progressively so, for years; then supervened profuse menstruation, and finally a severe uterine hæmorrhage which nothing would check till it carried her off. Epistaxis, too, is common as a secondary result. Sometimes cerebral hæmorrhage may ensue and carry off the patient, but this is not common. More frequently towards the close of life petechial and purpuric eruptions occur, and beneath serous membranes, and the dura mater ecchymoses are common, as well as in the substance of mucous membranes. In one very curious case, both in its rapid development, intense character, and as rapid recovery, recently recorded by Lachmann from Riegel's Clinic at Giessen there developed during the progress of the anæmia a considerable tumour in the iliac region, with œdema of the lower limb on that side; from its physical characters and manner of disappearance it was conjectured (and with probable truth) that this swelling was due to a hæmorrhagic effusion beneath the peritoneum. The patient was a young man of nineteen, and the anæmia had developed rapidly with no other exciting cause than heavy walking through snow. That patient, like the great majority of those in whom the anæmia is profound, presented retinal hæmorrhages. These hæmorrhages and the other retinal changes, œdema of the disc, and neuro-retinitis have been described and figured by Drs. S. Mackenzie and Gowers, the latter of whom says:—"The extravasations are often numerous, and more or less striated or flame-shaped from their situation in the layer of nerve-fibres. They are usually most abundant around the optic nerve-entrance. They are frequently associated with white spots and areas, due in part to leucocyte-like cells, in part to degeneration in the disturbed retinal tissues. Occasionally a pale spot may occupy the centre of a small hæmorrhage."[7] Quincke in his 31 recorded cases met with retinal hæmorrhages in all but 7—and notes the rapidity with which they disappear. We cannot, I think, regard them as invariably present; although their existence is a very valuable indication of the advanced stage of the disease. Moreover, as they are not commonly met with in other forms of anæmia, their presence has a certain diagnostic as well as prognostic value; but on the latter point Quincke gives cases which have recovered. Of the 110 cases (which include Quincke's) there are only 39 in which the ophthalmoscopic examination is recorded, and in 30 the hæmorrhages were found, but only 17 were fatal cases, 1 left unrelieved, and no fewer than 11 were regarded as recovered. Of the 9 cases in which these hæmorrhages were *absent*, 6 were known to end fatally. I should not like to lay much stress upon such meagre statistics; especially as it is possible that the traces of previous hæmorrhage might have escaped the observers; but so far as they go, they point to this—that retinal hæmorrhages do not imply a fatal termination, and that their absence does not necessitate a favourable prognosis.

---

[6] Die Progressive Perniciöse Anæmie. Zurich, 1877; kindly lent me by Dr. Pye-Smith.

There is usually no enlargement, or to only a slight degree, of either liver or spleen or lymphatic glands, and in only a very few cases has any special tenderness been noted over the bones.

Albuminuria, slight and transient, has been noted; but as a rule the urine is free from this abnormal constituent, of low specific gravity, mostly pale, sometimes high coloured, and deficient in urea and uric acid; but the latter constituent is not diminished in proportion. Chlorides are reduced (Hugenin), but the excretion of phosphoric acid is said to be increased relatively to the nitrogenous matters (Edelfesen). A marked indican reaction was always observed by Hugenin. In one case recorded by Dr. Finny of Dublin[8] the interesting observation was made by Dr. Emerson Reynolds of an appreciable quantity (viz., 0·308 grain in 72 ounces of urine) of iron in the urine sixteen days after treatment by iron had been discontinued.

There remains another symptom of peculiar significance—viz., pyrexia. The charts before you, both from marked cases of the disease—one by Immermann, the other by Quincke—illustrate the irregular course taken by the temperature, and this often without any concomitant changes appreciable in the patient's condition. The former (Chart 1)[9] is that of a single woman aged thirty-one, who was under treatment at Basle from August 23rd, 1872, to September 19th. The case is of some interest, for she had chlorotic symptoms develop when the catamenia began, at the age of seventeen; but apparently recovered completely. The symptoms dated from three weeks before admission, when she became feverish and lost appetite, and anæmic. The anæmia rather rapidly increased, and with it its cardio-vascular signs developed, but no retinal hæmorrhages. An appreciable hemiparesis of the facial muscles and of the tongue made the diagnosis difficult, so that the possibility of ulcerative endocarditis was entertained. Some diarrhœa occurred towards the close of the case. Slight splenic enlargement (no increase of white corpuscles) was also present. The post-mortem examination revealed, in addition to an enlarged firm spleen, only the anæmic condition of organs and fatty changes met with in pernicious anæmia. No brain lesion was found to account for the facial and lingual paresis. The other case (Chart 2, Case 11 in Quincke's series[10]), is that of a woman thirty-three years of age, who had been married nine years and had two children, the younger of whom, aged four, she had suckled for six months. She came into hospital on May 11th, 1876, having for five months suffered from debility, palpitation, and vertigo. She lived in very poor circumstances, and was admitted in an extremely weak and anæmic state. Cardio-vascular signs of anæmia were marked; there were retinal hæmorrhages and œdema, and the blood showed marked variations in the red corpuscles, their numbers being only 143,000 per cubic millimetre (1-38th). Transfusion was performed on May 24th, and the chart shows the course of the temperature for the following days, so that its irregularities must, I suppose, hardly be considered as due to the anæmia alone. This patient recovered, left the hospital on Aug. 25th, and was seen again in November, looking well-nourished and healthy. The third chart (No. 3) is one where profuse menorrhagia was added to the anæmia, the details of which I propose to give presently. As a rule, the temperature is liable to sudden exacerbations, sometimes reaching remarkable heights (in one of Dr. Finny's cases 106°) from a normal or nearly normal level; or it may have a more or less continuous course, varied by such exacerbations. Exceptionally there is no abnormal rise of temperature throughout. The apparently paradoxical event of fever occurring under conditions of diminished oxygenation—as in anæmia—is discussed by Immermann, who points out that the same obtains in leukhæmia and Hodgkin's disease—between which affections and anæmia there is the common link of poverty in red corpuscles. He shows also that the temperature rises after copious venesection; and the instability of temperature in anæmic convalescents is well known. He is inclined, then, to relate the pyrexia to the reduction in red corpuscles below a certain point; not that it is produced by increased metabolism, but by the decay of the tissue elements—their conversion from complex unstable compounds into more stable substances—a conversion which must be accompanied by the setting free of heat, although not requiring increased oxidation. And to

CHART 1. (IMMERMANN.)

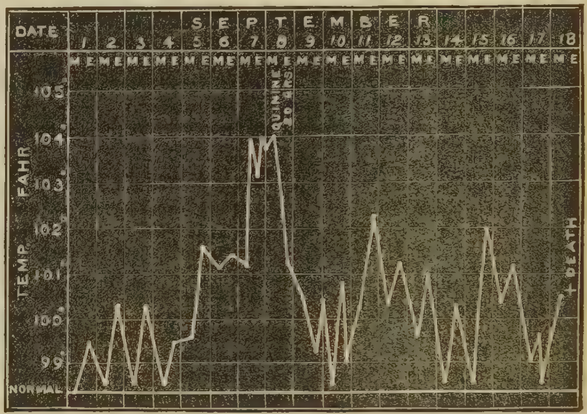

CHART 2. (QUINCKE.)

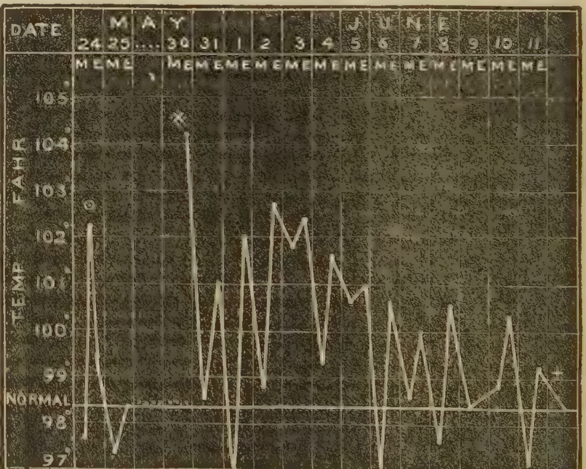

⊖ Transfusion. Collapse during operation, followed by sensation of cold, but no rigor. * Rigor. † From this date the course was apyrexial.

this increased heat-production, combined probably with heat-retention, he attributes the "anæmic fever" of these diseases. The blood has, when examined, been found to be altered; but I will speak of that when I come to discuss the pathogeny of the disease.

It is not easy to fix the duration of many cases. The patients themselves cannot tell when their anæmia began, and some have been, they say, pale all their life. Of the series of cases I have collected (viz., 110) I find that in 32 the total duration of symptoms was from one to six months; in 24 from six to twelve months; in 25 from one to two years; and the remaining 12 for periods exceeding two years. As many writers only speak of many weeks or months, such estimation does not include all the cases; and in those cases where the symptoms date back only a few weeks there is often found a history of some antecedent anæmia or a period of variable length of slight languor and ill health.

There can be no doubt that pernicious anæmia is not invariably fatal. Cases of recovery have been recorded by Quincke and others, where all the symptoms have been marked. Dr. Finny gives a striking case, and of the series to which I have so frequently referred no fewer than twenty are regarded by their observers to have recovered. Some of these did recover perhaps permanently, but of this it is not possible to speak with certainty, the last-recorded note often referring to them as being in perfect health; and these were cases which clinically were indistinguishable from those that ran a lethal course; some of them undoubtedly were rescued by prompt transfusion, and others got well under medicinal treatment; but their occurrence is encouraging, the natural tendency of the disease being undoubtedly towards death. Four cases passed away unrelieved; and 4, after an apparent recovery lasting a few weeks or months would relapse into the previous state, to again be temporarily restored to comparative health—once more to relapse without possibility of recovering. The greater number, however, die (86 out of 110) sooner or later (4 of these after temporary recovery and relapse), the mode of death being a simple asthenia and exhaustion, or passage into a comatose condition, or in syncope, or by dyspnœa, or convulsions. To briefly paraphrase Müller's vivid description of the manner in which death approaches: the distress attains a painful intensity, sleep is hindered by the constant beating in the head, the hum and roar in the ears, whilst the faculties became dim and unspeakably dulled. Vertigo and headache grow so severe that even sunlight causes pain. The prostration and weakness are so great that spontaneous effort is annulled, and the slightest movement, even the weight of the bedclothes, is irksome, and the patient groans and sighs in his distress. Now and then, towards the close, the hunger for air grows excessive, complaints are made of the painfulness with which every breath is taken, and relief is begged from this tormenting need. Some become so feeble, and sink into so deep a lethargy, as to cease to take interest in anything, or they lie impassive, breathing deeply and heavily, pale as a waxen figure, motionless as a corpse. Others toss restlessly from side to side, and in their delirium make vain efforts to escape, and then die suddenly from exhaustion. What is this but the picture of death from loss of blood—a loss, not from hæmorrhage, but from impoverishment of the blood in its chief elements?

The post-mortem appearances show extreme pallor of the surface and viscera. There is often a considerable amount of subcutaneous fat, and frequently slight œdema of the lower limbs. Dropsical effusions, never to large amount, occur in the serous sacs. The blood is fluid, thin, and watery, and scanty, pale clots are mingled with the fluid blood in the chambers of the heart. Hæmorrhages are met with in the form of subcutaneous ecchymoses, and similar extravasations beneath the pleura, pericardium, intestinal mucous membrane, and in the pia mater. Sometimes blood effusions of large amount occur in the latter situation. But the brain is pale, bloodless, and "wet" from œdema. The lungs are generally œdematous, and, owing to the fluidity of the blood, appear engorged in their dependent parts, contrasting with the marked anæmia of their other portions. Almost without exception the heart is in a state of fatty degeneration; its walls are pale, flaccid, and friable; the interior of the ventricles, particularly of the left ventricle, show irregular whitish striæ running transversely across the muscular bundles, and especially the papillary muscles, an appearance to which Dr. Quain gave the name of "tabbycat" striation. Microscopically the muscular fibres are pale, and destitute of striation, granular, or loaded with fatty molecules and cell globules of various sizes. Opaque patches of fatty degeneration occur on the mitral valve and stud the lining membrane of the aorta. Fatty degeneration of the intima of the smaller arteries, and even of capillary walls (especially in the retina) are observed, and serve to explain the liability to their rupture and hæmorrhage. Sometimes, but not invariably, there is fatty degeneration of the liver and kidneys. The spleen, lymphatic glands, and supra-renal capsules do not show any changes from the normal (except sometimes slight enlargement of the spleen), but in some cases the bone-marrow is found to be of a red colour and to show microscopical evidence of marked hyperplasia.

Such in brief are the essential features of progressive anæmia.

ON A CASE OF

CAROTID ANEURISM TREATED BY DIGITAL COMPRESSION AND SUBCUTANEOUS INJECTION OF ERGOTIN.

BY EDWARD BELLAMY, F.R.C.S.,
SURGEON TO CHARING-CROSS HOSPITAL, HON. FELLOW OF KING'S COLLEGE, LONDON.

I MAY mention at starting that, although I cannot record an absolute cure in this case, there was such marked and decided improvement that I feel convinced had my patient allowed an extension of the treatment adopted I should have been enabled to add another to the list of successful cases of digital compression. As to the action of the ergotin I am somewhat sceptical.

Mrs. C——, aged sixty-five, stout and florid, was brought to me in March, 1880, by the late Dr. Campbell, of Westbourne-place, with an aneurism at the root of the neck on the right side. After most careful examination, instituted on several occasions, before I began treatment, I made out that the aneurism was situated at the commencement of the right common carotid, and that, as far as my diagnosis went, the innominata was free. The tumour was freely expansile in all directions, was increasing, and the "whirring" noise well heard even without the stethoscope. The internal jugular vein was not compressed, and there was consequently no venous congestion of that side of the head and face. No difficulty in swallowing was complained of, neither had the tumour caused any displacement of the clavicle. There was no dyspnœa. The sac was very thin, and, in one point in particular, felt as though it might give way at any moment, more especially as my patient was an active woman, with a strong will of her own, and accustomed to take a great deal of physical exertion. The skin over the aneurism was movable and not reddened. The pupils on both sides were equal, and responded in the same degree to light. No difference could be detected in the temperature of the two sides of head and face.

Mrs. C—— decidedly objected to any "operation," and would not hear of it; yet, as far as I could judge, both from its position and the ease with which the trunk of the vessel above the tumour could be got at, it would have been a suitable case for distal ligature. Moreover, she would not hear of an anæsthetic for the "rapid" method of pressure. I noticed, however, that Chassaignac's tubercle (transverse process of sixth cervical vertebra) was very distinct, and that the vessel seemed of normal lumen as it passed over it. I therefore determined to try digital pressure on this tubercle, not with such force as to occlude the artery entirely, but to slow and diminish the current through the aneurism.

As Langenbeck, Dutoit, and others had apparently had such good results with the assistance of the injection of the watery extract of ergot, I determined to give it a trial, and before the first day of pressure (March 9th) I injected subcutaneously in the neighbourhood of the tumour two grains, dissolved in one part glycerine to five of alcohol. On March 10th, with the help of my late colleague, Mr. Amphlett, and Messrs. Whitehead, Clarke, and Turton, I commenced digital pressure on the vessel over the tubercle.

The pressures were maintained on the succeeding days as follows. On those marked with an asterisk the ergotin was used in doses increasing to three and a half grains:—

March 10th	3·5 hours.	March 16th	4·5 hours.
,, 11th*	3· ,,	,, 17th	2· ,,
,, 12th	3·5 ,,	,, 18th	3· ,,
,, 13th*	5· ,,	,, 19th	3·5 ,,
,, 14th	3·5 ,,	,, 20th	3·5 ,,
,, 15th*	3· ,,	,, 21st	3· ,,

Total ....41 hours.

As regards the applications of the pressure they were divided between the morning and the afternoon, an average of 1·5 hours at a time, which was all the patient could bear, on account of pain, which was complained of after a few minutes' pressure on the side of the head corresponding to the aneurism. The skin over the artery at the place where compression was applied was at times protected with a piece of amadou, and fuller's earth was powdered on before the compression commenced. At times, in order not to chafe the skin, pressure was made a little lower down on the distal mouth of the sac. The skin at no time was abraded. On the 15th I left off the ergotin, as it gave rise to very uncomfortable symptoms—sickness, local pain, and general uneasiness. Very soon after commencing pressure, a great difference was noticeable in the character of the pulsation in the tumour; it was much reduced, and the mass was evidently solidifying. On the 19th the bruit was very slight, and on the 21st, the last day, was quite imperceptible. At this date the aneurismal sac seemed perfectly solidified, although it was evident that there was a small channel through it which let blood into the carotid beyond, since it could be felt, though with difficulty. The character of the pulsation in the sac was that of one administered by the blood-current in the innominata, and not a distending one existing in itself. Mrs. C—— now showed signs of fatigue from the pressure, and resolutely refused further treatment. I therefore constructed an apparatus consisting of a hollow air-pad, which I retained over the tubercle by means of a modified Esmarch, but I found my patient would not use it.

Another day or perhaps another two days' pressure might have cured the aneurism. As it was, Mrs. C—— after leaving town began using the arm in various violent ways, and, from what I subsequently heard, undid a good deal of what had been done for her.

The case, though incomplete, is encouraging, and it would seem, with a little more assistance on the patient's part, might have been attended with a most satisfactory result.

Wimpole-street, Cavendish-square.

NOTES ON

VACCINATION AND REVACCINATION.

By G. E. YARROW, M.D.,

PUBLIC VACCINATOR AND MEDICAL OFFICER TO THE HOLBORN UNION.

AT a time like the present, when an epidemic of small-pox prevails, it is highly necessary that public vaccinators and others should know the full extent to which they can use the chief preventive means without being charged with over-zeal, or, still worse, cupidity. Considering the length of time the Vaccination Acts have been in operation, one is astonished at the number of contradictory statements as to the mode of working them that are continually appearing, apparently upon the best authority, and even the opposition to carrying them out by those who should evidently be among their strongest supporters. With a view to eliciting the opinion of others I should like to refer to a letter which appeared in *The Times* of Feb. 24th, from Mr. Blennerhassett, in which he calls attention to a report of the medical officer of the Lambeth Infirmary, to the effect that he is in the habit of vaccinating infants twenty-four hours old, and to a circular letter of the Local Government Board recommending that the operation be performed on infants born in the workhouses and Poor-law infirmaries within six days of birth. Mr. Blennerhassett says: "Several medical men have, I believe, protested against these arbitrary measures, as fraught with imminent risk and danger to infant life, and many persons will object to them as involving a treatment of the children of the poor in workhouses and infirmaries entirely different from that which is enforced by law, or would be tolerated by public opinion, with respect to the vaccination of the children of the well-to-do classes."

In the first place, I am surprised to read that there exists any medical evidence of "the imminent risk and danger to life" resulting from early vaccination, as for some years I have diligently sought for such evidence, and the result has only been to confirm the experience I gained during the last small-pox epidemic, when I vaccinated between five and six hundred infants under seven days old, and I cannot call to mind one case attended by any untoward result; on the contrary, I found that the local inflammation so frequently seen in infants a few months old was rarely seen in the very young; and this I believe is accounted for by the very limited amount of movement of which the child is capable, and the low degree of sensibility of the skin at this time of life must reduce the pain of the operation and progress of the vesicle to a minimum.

Another point of great moment in reference to the vaccination of pauper children is that during residence in a workhouse they have the care of nurses and mothers which cannot be found after leaving, for even when the parent is a married woman she is usually compelled to seek her livelihood by following some employment which necessitates her absence for several hours at a time, during which the child is left to the tender mercy of a stranger or, as our great modern author puts it, "the giant child in charge of a dwarf nurse."

Many persons will join Mr. Blennerhassett in his lament that the treatment demanded of children born in workhouse infirmaries differs from that required of children of the well-to-do classes. But what alternative is there? The majority of the children are the offspring of unmarried women who leave the institution from ten to twenty days after confinement, and who cannot tell where they may next find a home, much less where the children may be found at three months old. If they are sent out unvaccinated they go forth for the most part to our densely populated localities to form possible foci of future epidemics. That evidence is not wanting to convert this possibility into a probability is demonstrated by an instance which has recently come under my notice.

A. K——, the child of an unmarried woman, born in the City-road workhouse, left at three weeks old. After having lived in several other places, the mother took apartments in one of our most densely populated thoroughfares; here the child was taken with small-pox and died last January, unvaccinated, aged eight months. An elder child belonging to the same woman is now in the small-pox hospital. Two young men residing in the house have been removed to the hospital, one of whom, aged nineteen, has since died. The child of a neighbour has also died unvaccinated (the father of this infant is a potman to a neighbouring beer-house). The child of a fourth family has been lying in a dangerous condition from the same disease (also unvaccinated). The mother of this child was in the habit of going backward and forward to the first case (A. K——) while the child was lying ill, and during this period her children were attending a board-school, from which there are now absent seven other children suffering from small-pox. Now, I think it is fair to assume that if the child A. K—— had been vaccinated three lives would have been spared, thirteen cases of small-pox prevented, and the cost of maintaining these patients at the public expense saved.

At the Holborn Union Infirmary, City-road, it is an instruction not to vaccinate until the children attain the age of six weeks. One hundred and fifty-seven children were born in this institution last year, twenty-four only of whom were operated upon before leaving, and therefore 133 infants were sent out without that protection, or the smallest guarantee of that obedience to the law which is demanded of persons in better circumstances, and which the latter in turn have a right to expect shall not be evaded by those whom they contribute to support.

In response to the circular letter of the Local Government Board, I am informed that the Guardians of the Holborn Union at their last meeting passed a resolution that all children born in the workhouse be vaccinated at fourteen days old, *subject to the consent of the mother*. The practical result of this change will be that instead of 16 per cent. of the children being vaccinated, as heretofore, there will now be none. For even if they remained long enough any-one may perceive how useless it would be to waste time in arguing the point with the class of persons I have described.

On referring to the Consolidated Orders of the Poor-law

Board, under the head of "Duties of the Workhouse Medical Officer," Article 207 directs, among other things, "to vaccinate such of the children as require vaccination;" and a foot-note to this order says: "It not unfrequently arises that the parents of children in a workhouse will not allow the medical officers to vaccinate their children. In answer to an inquiry as to whether the guardians had the power to cause such children to be vaccinated without the consent of the parents in such a case, the Commissioners have stated that they are of opinion that the guardians have, without the permission of the parent, the right to vaccinate any child in their custody, during any danger of contagion from small-pox."

Again, Official Circular, vol. vii, p. 204: "The Poor Law Board have expressed an opinion, that if the guardians and the workhouse medical officer think that *any* child in the workhouse requires vaccination, the medical officer should vaccinate such child notwithstanding the objection of the parent."

My object in quoting the above is to show that the guardians have the power to cause vaccination to be performed on children in workhouses without the consent of the parents, although statements to the contrary are continually being made. That the regulations as to revaccination at the public expense are not generally understood is shown by a report in the LANCET of February 26th, which states that Dr. Barclay, in calling the attention of the Chelsea Vestry to the matter, said that the Local Government Board would not sanction the payment for revaccination of children under fifteen years of age. In your note on the subject you say: "Revaccination may be given at the public expense if the applicant has attained the age of fifteen years, or, if during any immediate danger of small-pox, the age of twelve years, and has not before been successfully vaccinated." Surely, at whatever age vaccination is performed for the first time it is primary, and payable for as such.

The Vaccination Act of 1867 (Sec. 8), after rescinding contracts providing for payment for revaccination then in operation, authorises the Privy Council to make provision for revaccination and for the amount to be paid for the same. The Act of 1871 provides (Sec. 9) that a fee of two shillings and sixpence shall be paid by anyone who does not allow the result of revaccination to be ascertained by the Public Vaccinator or his deputy, and (Sec. 13) provides for revaccination by Poor-law medical officers in houses where they are attending persons suffering from small-pox, but beyond these two references this Act makes absolutely no provision for revaccination. The form of contract does not contain a word on the subject, but a Privy Council letter, dated Feb. 18th, 1868, indicates the extent to which revaccination at the public expense may be given as follows:—"The performance of revaccination by the Public Vaccinator on persons applying to him for that purpose shall be limited in each case by the following conditions:—1. That, so far as the Public Vaccinator can ascertain, the applicant has attained the age of fifteen years, or, if during any immediate danger of small-pox, the age of twelve years, and has not before been successfully revaccinated; and (2) that, in the Public Vaccinator's judgment, the proposed revaccination is not for any sufficient medical reason undesirable; and (3) that the Public Vaccinator can afford vaccine lymph for the purpose without in any degree postponing the claims which are made on him for the performance of primary vaccination in his district."

Even the limitation prescribed in this letter is to be regretted, for the experience gained during the last epidemic, and which is being corroborated by the present outbreak, clearly proves that there are degrees of protection afforded by vaccination, but one mark, unless it be very large, is not as good as five or six, and the admissions of vaccinated persons into our small-pox hospitals are in an inverse ratio to the number of vaccination marks which they possess.

Old-street, E.C.

BRISTOL INFIRMARY.—The report of the committee of this institution, read at the annual meeting on the 23rd ult., was, from a financial point of view, of a decidedly gloomy character. Whilst the expenditure during 1880 was £13,116, the income stood at £11,198, showing a deficiency of £1918, while there was a balance due to the treasurer of £8816. The remark of the president, that it would be a lasting shame to the great and wealthy city of Bristol if the committee had to close any of the wards of the charity, must, we think, be endorsed by his fellow-citizens.

THE PATHOGENY AND TREATMENT OF BRONCHOCELE OR GOITRE.

BY EDWARD WOAKES, M.D. LOND.

(Concluded from page 498.)

CASE 9.—A. S——, a female, aged eighteen, in service at Stratford. The tumour had existed two years. On Dec. 11th, 1877, presented simple goitre; girth 13¼ in. At first patient was treated with bromides, iodides, and iron for three months; under this treatment goitre enlarged to 13¾ in. On March 22nd, 1878, she was given fifteen minims of dilute fluoric acid. This in April was increased to thirty minims; swelling disappearing. On June 21st scarcely a trace of enlargement. Time of taking acid three months.

CASE 10.—S. H——, aged twenty-six years, a laundress, living at Islington, had noticed the enlargement four years ago. In September, 1877, patient presented a firm tumour the size of a tennis ball, occupying the isthmus, and a portion of the right lobe of thyroid body. There was deep-seated fluctuation, but from the thickness of the cyst-walls and extreme tenseness of the swelling this was somewhat obscure. It was diagnosed as a fibro-cystic goitre; girth of neck 15¼ in. Wishing to test the acid in this phase of the disease, the patient was given fifteen minims in water three times daily, on Sept. 4th. On Sept. 18th the girth was 15 in. On Sept. 25th she was seen by an assistant, who injected the tumour with twenty minims of tincture of iodine. After this a thin clear fluid continued to ooze through the puncture made by the needle during two hours. On Oct. 2nd the girth was reduced to 13½ in., owing to the escape of fluid, and the contracted cyst-wall, about the size of a walnut, was distinctly to be made out. On Nov. 20th scarcely a trace of this remained, and the patient was discharged cured. Time of treatment three months.

Remarks.—The above case has been already alluded to in the opening paragraph of this paper. It is unique in its way, for, though the orginal design of the treatment was frustrated by the inadvertent tapping as detailed, it afforded the unexpected result of a fibro-cystic goitre of considerable size and long duration recovering in three months with no other treatment than that recorded. The puncture and injection were made on the assumption that a fibrous goitre was being dealt with. The iodine could scarcely have affected the result, as, being diffused through the contained fluid of the cyst, it must have escaped immediately with it. It is opposed to general experience for a cyst so tapped not to refill. To the absorptive influence of the acid on the solid portion of the tumour, indicated by its diminution during the three weeks it was taken preceding the tapping, may with fairness be accorded the change in its character, which averted the secretion of fresh fluid, and ended in the rapid disappearance of the disease.

CASE 11.—H. R——, female, married, residing at Chelsea, presented a mixed goitre of one year's duration, Sept. 7th, 1877. Blistering fluid was applied to the swelling, and she was given ten minims of dilute fluoric acid three times a day. On Oct. 5th she was so much better that she did not attend subsequently. This case was of a mild type, and illustrates the advantage of a combination of local treatment with the fluoric acid internally.

CASE 12.—C. K——, a female, aged twenty-eight, married, living at Old Ford, presented on March 12th, 1878, a goitre of five years' duration. The right lobe was of the firm, fibrous, and the left the soft or simple variety. On both sides the enlargement rose to the level of the hyoid bone. Girth 14⅜ in. At the above date she was given fifteen minims of dilute fluoric acid twice a day. On March 22nd it was increased to twenty minims. On April 9th the girth was 14 in. On April 30th the dose was increased to thirty minims, and on May 21st to forty minims. The girth was now 13½ in. On May 28th the entire tumour had subsided to the normal dimensions of the gland. Time, three months.

CASE 13.—E. B——, female, aged seventeen, on October 23rd, 1877, presented a small recurrent fibrous enlargement of the isthmus. She took fifteen minims of fluoric acid twice a day for three weeks, at the end of which time only a trace of the enlargement remained.

CASE 14.—L. R——, a female, aged twenty-nine, married, living in the Waterloo-road. She had been the subject of goitre since the age of eighteen. Commenced treatment in July, 1875. Came under the author's care in January, 1877, having received little or no benefit from the previous treatment. The tumour was very firm and large, dipping deeply into the neck, chiefly on the right side. The pressure on the œsophagus was such that she had been unable to swallow solid food for six months. Breathing much impeded; her general health was very bad, and she was excessively weak. She took tincture of perchloride of iron and cod-liver oil up to August, 1877, when a seton was passed perpendicularly through the entire length of the tumour. This was followed by a free discharge of the thin offensively smelling fluid, with very slow diminution of size, and the gland was extremely tender. This state of things continued till February, 1878, when she commenced taking fifteen-minim doses of dilute fluoric acid, which were shortly increased to twenty minims. On March 19th the seton was removed. There was a marked improvement in her health; she could swallow solids. The swelling was now about the size of a hen's egg, and very hard. On April 30th the dose of the acid was increased to thirty minims. The upper wound made by the seton had healed, but the lower one discharged freely. Tumour much smaller and less painful. In July she was taking fifty minims. This dose in September caused inconvenience and was reduced to thirty minims. In November there was a further diminution of the tumour and the acid was increased to forty minims. This dose at times caused gastralgia and faintness, on which account she was directed to intermit the medicine at intervals. In June, 1879, there was still some discharge, though the tumour was reduced so much that it occasioned no inconvenience. She was last seen in the spring of 1880, when a nodule about the dimensions of a filbert was all that remained. She was in robust health, and did not attend subsequently. Time of taking acid, about two years.

Case 15.—A. D——, youth aged fifteen years, had noticed his neck enlarging for a year previous to January, 1878. He was then living in Berkshire. His mother was goitrous. The tumour extended chiefly vertically, and was of the soft variety. He commenced the acid on January 21st, taking ten minims; this was followed by rapid increase, so that the growth, which was 13½ in., became in the course of a week 14½ in. He continued the acid for six months, attaining a maximum dose of forty minims. During this time the perpendicular dimensions of the swelling diminished, and the growth became normal, but the improvement was very slow. A later report, received about fifteen months from the commencement of treatment, states that the disease had nearly disappeared.

Case 16.—E. S——, a female, married, aged thirty-three years, living in Soho, presented in February, 1878, a swelling of medium hardness in one lobe, of the size of half a walnut. She began with fifteen minims of dilute fluoric acid, which were shortly increased to thirty-five minims. There was no improvement by August; on the contrary, the growth had enlarged considerably. After this trial of eight months without benefit the acid treatment was relinquished.

Case 17.—E. H——, a female, aged twenty-six. Seen Sept. 1878. The disease commenced when living in Essex, five years previously; she moved to Hackney three years since, and during this time the enlargement had much increased. She presented a fibrous goitre, chiefly of the right lobe, extending upwards and backwards. She suffered much from dyspepsia, and generally feeble health. Commenced with fifteen minims of dilute acid on Sept. 11th, and on Oct. 9th the dose was increased to thirty minims. This dose caused sickness, and was first reduced, and then discontinued. Recommenced, in January, 1879, with thirty minims, which in February were increased to fifty minims. Again the sickness returned, and the medicine was discontinued finally. The failure was probably in some degree due to the irritable state of the digestive organs. The dimensions were the same as at the commencement.

Case 18.—A. K——, a male, aged sixteen years, living in the Strand. Seen June, 1878. He presented a mixed goitre of one year's duration; girth 14½ in. Commencing with twenty-five minims of dilute fluoric acid, the dose was increased to sixty minims during the ensuing five months. No improvement occurred during this time. Failed.

Case 19.—Mr. A——, aged forty, was seen in consultation at the close of 1879. She had a large, firm, fibrous goitre of the entire gland of many years' duration. She was ordered to take half-drachm doses of fluoric acid in water. As she returned to the country I have not seen her since, but received from her medical attendant in October, 1880, a report to the effect that the acid was taken for about six months, and that "her neck has never been so small as now during the eight years I have attended her, notwithstanding she has had iodine, &c. Had she persevered with the fluoric acid I feel sure the result would have been complete."

Case 20.—S. C——, aged twenty-four, housemaid (Feb. 1880), states the enlargement has existed as long as she can remember. She lived in Essex till the age of fourteen, when she came to London, since which it has increased, especially during the last year. Her mother is goitrous. There is a fibrous goitre of isthmus and right lobe, very firm and large. Feb. 13th, commenced with twenty minims of dilute fluoric acid; Feb. 24th, increased to half drachm doses; March 2nd, to forty minims; March 9th, to fifty minims. Goitre smaller and softer. April 6th, increased to sixty minims; April 29th, to seventy minims. This was continued to September, at which time careful examination revealed only a trace of thickening behind the sterno-mastoid muscle. She did not attend afterwards. Cure.

Harley-street, W.

GONORRHŒA FOLLOWED BY ABDOMINAL TUMOUR; CONTENTS REMOVED BY ASPIRATOR; RECOVERY.

By WILLIAM ALEXANDER, M.D.,
SURGEON-MAJOR, ARMY MEDICAL DEPARTMENT.

Corporal O. L——, aged twenty, a strong healthy young man, but with a phthisical family history, was admitted to hospital on Aug. 18th, 1880, suffering from an attack of gonorrhœa. Ordered a saline cathartic, an alkaline mixture, and to remain in bed.

Aug. 26th: Urethral discharge ceased; the patient feeling unwell, and unable to eat.—27th: Complained of pain in left lumbar region; skin hot; the thermometer in the mouth registering 105°. Was ordered one ounce of diaphoretic mixture with one minim of tincture of aconite every hour, which reduced temperature.—28th: Skin still hot, and tongue furred.—29th: Had an attack of bilious vomiting; temperature 102°; no sore-throat or any pain except what he describes as a "horrid pain" in left lumbar region. Nothing can be detected to account for this condition; hot fomentations give no relief.—30th: Still in the same condition. Ordered a hot bath; diaphoretics with small doses of tincture of aconite.—31st: No improvement; tongue covered with a long white fur; pulse 88, soft and regular; temperature, morning 101°, evening 103·2°.

Sept. 1st: Much the same. Temp. 101°; bowels acted well. From this date till Sept. 6th the condition remained unchanged. A "horrid pain" in left lumbar region, a thickly furred tongue, a pulse varying from 75 to 88, and a temperature of about 101°, rising in the evening to 102° or 103°.—6th: Complained that the pain was extending round the back to the right side. On examining him on this date, detected a small immovable tumour two inches to the left and on a line with umbilicus, having a doughy feeling. Considered it an accumulation of fæces. Ordered castor oil, which was followed by an enema administered by a long tube.—7th: At evening visit found patient moaning and restless, bathed in perspiration, and calling out about the pain in his back; tongue hard and brown. From this date hypodermic injections of morphia had to be given to keep patient quiet.—8th: Asked Mr. J. Appleyard to see the case with me, the tumour being then prominent and immovable and the size of a large orange, and with the same doughy feeling. The nature of the tumour was discussed. There was no bruit, no pulsation; in fact, no indication as to its nature. To make assurance doubly sure, it was decided to clear the bowel by a strong purgative. Castor oil, with croton oil, was administered and followed by enema.—9th: The bowels acted freely, but without effecting any change in the tumour. Temperature, morning 100·6°; evening 102°.—13th: Tongue furred and brown; temperature, morning 100°; evening 102·6°. Detected an obscure feeling of fluctuation in tumour.—14th: A decided feeling of fluctuation observed. Temperature, morning 101·2°; evening 101°.—15th: Very weak; face bathed in perspiration. Pulse 76; temperature 101°. The fluctuation can be felt round the left loin to within three inches of the spine. In consultation with Mr. Appleyard, a small-sized needle was introduced into the most prominent part of the tumour in front and two inches to the left of the umbilicus, and seven ounces of healthy pus withdrawn by aspirator, which relieved him very much.—16th: Much easier. Pulse, morning 80; evening 80; temperature, morning 101·4°; evening 101·4°.—17th: General condition somewhat improved; some tenderness at the seat of puncture. The same needle was again introduced close to the former puncture mark, and seven ounces of healthy pus withdrawn by aspirator.—18th: Complained of great pain at the seat of puncture; to keep a recumbent position.—20th: The tongue cleaner than it has been since the commencement of the disease. Pulse 80; temperature 100°.—23rd: Pulse 80; temperature, morning 100°; evening 99·2°. Removed twenty ounces of healthy pus, inserting the needle close to the seat of the former puncture. The propriety of withdrawing from behind was discussed, but the idea was ultimately abandoned.—25th: Very weak. Pulse 84; temperature 98·4°.—26th: The fluctuation more evident posteriorly than it has been.

Oct. 1st: Twenty-two ounces of healthy pus were removed as before, the needle being withdrawn on the first tinge of blood being observed in the pus, and an abdominal bandage applied. After this, for three days, the temperature was normal, the patient improving in strength. When he was able to move a little it was found that the lower lobe of the left lung was quite consolidated.—5th: Some pain at the seat of puncture of a dragging character; pulse 84. Temperature, morning 98·4°; evening 103°. After this for several days, though feeling quite easy, there was a high evening temperature, varying from 101° to 103°.—11th: General appearance much improved, tongue clean, appetite good, and sleeps well. From this date a gradual and steady improvement set in, the tumour gradually becoming less and less perceptible to the touch, till it gradually disappeared. The health rapidly improved, and the weight increased at the rate of 4 lb. per week.

Dec. 15th: Feels perfectly well. No indication of any tumour in abdomen, and a faint murmur can be detected in the lower lobe of left lung.—21st: Respiratory murmur perfectly re-established at base of left lung. The man states he feels as well as ever he did, and presents all the appearance of good health. Discharged.

Throughout this protracted case the urine was free from albumen, but loaded with urates; and so long as the absorption process was going on there was a considerable rise of evening temperature, which may have been assisted by the rapid development of tissue. The general treatment was on the broad principles of medicine and the free use of stimulants, without which the patient would have sunk at the most critical period. I am greatly indebted to Mr. J. Appleyard, of Bradford, for his kind assistance throughout this remarkable case.

On March 1st the man was in perfect health in every respect.

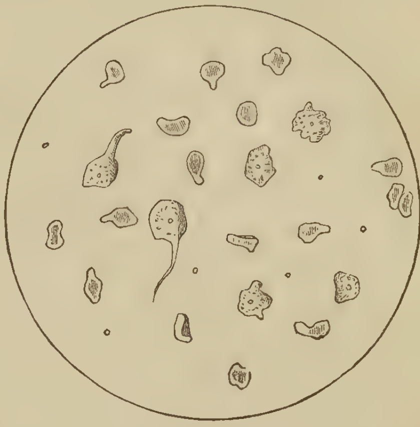
Bradford, Yorks.

THE BLOOD-CELLS IN ANÆMIA.

BY W. G. TACEY, L.R.C.P., &c.

THE recent published observations on the appearances of the blood-cells in anæmia by Dr. Bastian, Dr. Cavafy, and others have afforded to many a desire for further information and investigation on this very interesting subject. With this view I venture to offer a few observations upon two cases of anæmia kindly sent to me for examination; both were well marked instances of this condition, and of long duration. The blood in each case was microscopically examined under ⅛ objective immediately after removal from the finger of the patient, and was again examined eight hours afterwards under one of Zeis's high-power objectives. The white corpuscules were very abundant, more than the average size, and exhibited very feeble amœboid alteration in shape; but, after careful watching, I was at length able to distinguish decided pseudopodia in one or two cells, and more than once the prolongations reminded me of the filamentous protrusions of the Amœba princeps or the Actinophrys sol, as figured in Carpenter's "Microscope." If, according to Dr. L. Beale, these are vital movements, and the corpuscule possesses no cell-wall, vibratile filaments can be demonstrated by the aid of modified heat; or again, if, according to Cohnheim and others, the corpuscules are able to pass through the capillary walls (diapedesis), it does not appear so very improbable that these pseudopodia-like changes in the white blood-cells should occur.

With reference to the red corpuscules, considerable variations in the contour of these cells were evident enough; the general tendency seemed to be towards irregular curvation, and corresponded with the description communicated some few months ago by Dr. Finny and Dr. Churton.



In addition to this irregularity, I noted a slow oscillatory movement of these corpuscules, to all appearance identical with the molecular agitation usually seen in granular solids. If my observation is correct, and this motility is shown to exist, is the motion vital or physical? The red blood-cell is said to have no granular contents; therefore the movement cannot be included in the category of the so-called "Brownian motion."

On this occasion I also examined blood from a case of Bright's disease of some duration, and observed a similar want of uniformity in the outline of the red corpuscules; crenation was conspicuous by its absence. In this case the slow movement was evident, and could be seen several hours after removal from the patient. Here, again, the leucocytes were in abnormal quantity, but not so distinctive in size and number as compared with the abovementioned cases of anæmia.

OF
HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

WESTMINSTER HOSPITAL.

POPLITEAL ANEURISM, CURED BY THE APPLICATION OF ESMARCH'S BANDAGE.

(Under the care of Mr. MACNAMARA.)

FOR the following notes we are indebted to Mr. R. Sanderson.

C. T——, aged thirty-two, a fishmonger, who had been in the habit of drinking five or six pints of beer and smoking upwards of half an ounce of tobacco daily, was admitted on July 4th last. His general health had been good until about three weeks before, when, without any assignable cause, he began to feel great pain behind his left knee. His ankle and leg then commenced to swell, and after a day's work he noticed that the veins of the left leg were much distended.

On admission a pulsating tumour was felt in the left popliteal space, about the size of a hen's egg. The pulsation could be nearly stopped by pressure on the femoral artery.

The posterior tibial and dorsal artery of the foot could be felt pulsating.

Next day, at 3 P.M., Mr. Macnamara applied an Esmarch's elastic bandage from the foot to the lower border of the aneurism, and a second round the thigh above the knee, leaving the tumour uncovered. Owing to the patient being unable to bear the pain, ether was administered at 3.17 and continued till 3.55. Digital compression was then applied to the femoral artery, and the Esmarch bandage was removed. No pulsation was felt in the aneurism. At 5 P.M. the leg was flexed on the thigh, and, having been fixed in that position, compression of the femoral artery was discontinued. Slight pulsation was now felt in the aneurism.

On the 6th pulsation was more marked in the aneurism than on the previous evening.

On the 10th Mr. Macnamara, at 1.30, again applied Esmarch's bandage, carrying it up to the lower border of the aneurism, then a web elastic bandage was put on lightly over the knee, including the popliteal space and aneurism, and carried up to the lower one-third of the thigh. Ten minutes after the application of the bandage chloroform was administered, and the patient kept under its influence till 2.30. Digital compression having been applied to the femoral artery, the Esmarch's bandage was removed. On relaxing the compression a slight pulsation could be felt in the aneurism. Digital compression was kept up until 5 P.M. On being discontinued no pulsation was felt in the tumour. The leg was semi-flexed on the thigh, and the patient was kept in bed until the 19th of July.

No pulsation returned in the aneurism, a marked decrease in the size of the tumour could be felt every day, and the patient was discharged from the hospital on the 28th of the month.

He was seen six months after leaving the hospital. No perceptible remains of the aneurism could be detected, and the patient had long since returned to his work.

VICTORIA DOCK DISTRICT DISPENSARY.

SEVEN CONSECUTIVE CASES OF PLEURISY WITH EFFUSION; PARACENTESIS; REMARKS.

(Under the care of Mr. JULIUS CÆSAR.)

CASE 1.—Thos. M——, aged fourteen years, presented himself, complaining of a short, dry cough and shortness of breath. He had been under treatment elsewhere for two months for the same symptoms. On examination the left side of the chest was seen to be much larger than the right and measured one inch and a half more; dulness reached as high as the spine of the scapula behind, and to the third interspace in front. Respiratory murmur, vocal resonance, and vocal fremitus were absent. The heart's apex was pushed over to just inside the right nipple, all the signs of pleuritic effusion being well marked. The aspirator was used and thirty ounces of serum drawn off, when the patient complained of faintness, and the operation was stopped. The faintness soon passed off, and in a week he was able to resume his employment, that of an errand boy.

CASE 2.—A girl, aged seven years, complained of a pain in the right side, short, dry cough, shortness of breath, and feverishness. On examination friction sounds were heard over a small area at the angle of the scapula. A diuretic mixture was ordered and blistering fluid was painted over the side, followed by poultices. In four days more effusion was diagnosed. The same treatment was continued for a week, at the end of which time, the amount of effusion having undergone no diminution, tapping was resorted to, and eight ounces of serum were evacuated. In a week's time she was able to resume her attendance at school.

CASE 3.—A boy, aged three years, complained of pain in the right side, short cough, inability to lie on the affected side, shortness of breath, and feverishness. Examination revealed a small patch of dulness at the angle of the scapula, with diminished respiratory sounds, vocal resonance, and vocal fremitus. Two ounces of serum were drawn off, and in three days he was able to resume attendance at school.

CASE 4.—Male, aged three years, presented himself with a history similar in every respect to Case 3. A diuretic mixture, counter-irritants, and poultices were ordered and continued for ten days, but producing no beneficial effect, aspiration was had recourse to, and five ounces of serum were drawn off. Iodine liniment and a stout flannel roller were applied to the side. This treatment relieved all symptoms very much, but only for a few days, when his breathing became very much embarrassed. The temperature went up to 103°, and he began to have night sweats. Dulness now reached to within three fingers' breadth of the spine of the scapula behind, and to within two of the clavicle in front. All the symptoms pointing to empyema, tapping was determined upon, and fifteen ounces of thick pus evacuated. The iodine liniment and bandage treatment were resumed. The patient made a rapid and complete recovery.

CASE 5.—A tall and very anæmic girl, aged fifteen years, complained of all the usual symptoms, and presented most of the usual signs of pleuritic effusion. As her mother was at first unwilling to consent to tapping, tonics with iodide of potassium were administered internally, and counter-irritants and poultices were applied externally for a fortnight, but without benefit. The mother now consenting, the aspirator was used, and the fluid withdrawn. After this she improved rapidly, and was able to resume her occupation (that of a barmaid) at the end of a fortnight.

CASE 6 was that of a strong, healthy woman, aged twenty-six years, who, on presenting herself for treatment, complained of a stabbing pain just outside the right nipple, slight shortness of breath, short cough, and inability to lie on the affected side. Examination revealed friction sounds at the angle of the scapula, where there was slight dulness, with diminution of respiration sounds, vocal resonance, and vocal fremitus. Diuretic mixture and counter-irritants were ordered at the end of a week. Not having made any improvement she was ordered to wear a stout flannel roller, and to continue the other treatment for a week, at the end of which time, the amount of effusion not having diminished, tapping was resorted to, and twenty-nine ounces of serum withdrawn, after which she made a quick recovery.

CASE 7.—Male, aged twenty-one years. This case was in every particular similar to Case 6, except that a fortnight after the first tapping a second effusion into the same side—the right—took place, necessitating a second use of the aspirator. He was able to resume work in a week's time.

Remarks.—I think these cases are of interest, as showing, as far as things go—1st. The superiority of tapping, at least as regards time, over drugs. 2nd. That early tapping will effect an early cure. 3rd. That ægophony is rather a curiosity, in effusions from simple pleuritis, than otherwise. 4 That all cases of empyema do not require the use of injections for their cure.

LIVERPOOL NORTHERN HOSPITAL.

VESICAL CALCULUS; LATERAL LITHOTOMY; SUBSEQUENT DISCHARGE OF PUS FROM UMBILICUS; RECOVERY.

(Under the care of Mr. CHAUNCY PUZEY.)

THE following case seems exactly similar to one reported by Mr. Bryant, of Guy's Hospital, in THE LANCET for Feb. 26th of this year.

Thomas H——, a delicate, rickety-looking boy, ten years of age, was admitted on Jan. 28th, 1880. He was suffering from frequent painful micturition, the urine being loaded with phosphatic deposits and mucus, and having an alkaline reaction. On sounding, a large, rough calculus was at once detected.

On March 3rd, lateral lithotomy was performed in the ordinary manner, but on attempting the withdrawal of the stone it was found that in consequence of its size, and the small development of the child, extraction could hardly be effected without risk either of unduly bruising the neck of the bladder or of crushing the stone in the forceps. The right side of the prostate was therefore slightly incised with a hernia-knife, and then the calculus was readily extracted. It weighed within a few grains of an ounce, but was large compared with its weight, the main body of the calculus being composed of uric acid thickly coated with loosely arranged layers of phosphatic deposits. The boy suffered no pain or discomfort from the operation, but the wound was a long time in closing; the urine was generally turbid and alkaline, and the surface of the wound often covered with muco-pus and with phosphatic deposit. This state of affairs was to a certain extent successfully combated by daily washing out the bladder (by means of a catheter passed through the wound) with a weak solution of nitric acid. His general condition was decidedly improving. He had been in a miserable state on admission, and it appeared from his mother's statement that his urine had been thick and frequently ammoniacal for the past five years.

On February 18th some urine was passed per urethram, but the wound was not completely closed until five weeks after the operation. About this time his temperature, which had been very irregular, and generally above normal, began to run still higher, and, according to notes taken by Mr. Batty (one of the house-surgeons), on March 7th the boy complained of tenderness, on pressure, over the hypogastric and right iliac regions; there was also some tenderness in the situation of the right kidney; the urine was thick, and contained pus. On the 13th patient complained of increased tenderness in the parts above-mentioned, aggravated by any movement of the abdominal muscles, as in coughing. The abdomen was distended with flatus, and nausea and headache were complained of. The dyspeptic and tympanitic troubles were relieved by treatment; but the tenderness, swelling, and hardness of the abdomen increased both in degree and extent, being, however, all along much more marked in the right side of the abdomen, and the hardness never extending higher than the umbilicus.

On March 24th it was noted that just below the umbilicus there was a slight soft swelling, the navel itself being somewhat prominent and red. An abscess was evidently pointing here. The hardness remained in the hypogastric and right iliac regions and extended to this soft point at the umbilicus.—25th (9.30 A.M.): Two small opaque vesicles had made their appearance at the umbilicus, and at 2 P.M. they gave way, and about half a teaspoonful of thin pus escaped. Terebene oiled lint was applied to the wound and oakum poultice over this and the lower part of the abdomen.—26th: Abdominal tenderness less. Abscess had discharged freely during the night. Temperature normal for the first time since March 9th.

From this time the patient steadily improved. The abscess discharged freely, and, *pari passu*, the abdominal tenderness and hardness diminished.

On April 2nd the discharge had ceased, and on the 5th (two months after the oparation) the boy was allowed to get up for the first time, and shortly afterwards he was sent to Woolton Convalescent Hospital.

Remarks by Mr. PUZEY.—I ascertained that the boy was in good health two or three months ago, but have not seen him since he left the hospital. I suppose I am right in thinking that the case just recorded is a very rare one. Since it came under my notice I had made many inquiries, but I had not heard of a similar occurrence until I saw the case reported in THE LANCET of Feb. 26th; and it has been to me a subject of speculation as to what might be the explanation of this unusual course of events. Was it the result of some ulceration of the bladder, with slight leakage of urine through the opening, leading to urinary infiltration and abscess in front or at the side of the bladder, and travelling along the anterior to the urachus, to present at the umbilicus? Or might the urinary infiltration and abscess have resulted from the ulceration of some pouch formed by the prolonged pressure of the stone? In my case the history pointed to bladder symptoms noticed for five years before the operation. There is another possible explanation, which occurred to me whilst the boy was under observation, but of which I am more dubious since seeing the suggestion made by Mr. Bryant. In my case it was noticed that there was occasional tenderness in the region of the right kidney, and extending along the ureter to the bladder; it was also noticed that the urine sometimes contained masses of mucus and phosphates, and sometimes a marked quantity of pus, at other times it was comparatively clear. Was it possible that the valvular opening of the right ureter into the bladder was obstructed, giving rise to a saccular dilatation of the ureter just outside the bladder, and that thus the abscess arose? I have omitted to mention that there was no appearance of blood in the urine after the first two or three hours subsequent to the operation. There was no distinct trace of urine in the pus which came from the umbilicus. It will have been observed, as in Mr. Bryant's case, that the onset of the unusual train of events recorded coincided with or immediately followed the healing of the operation wound.

In a case of this sort, where fortunately no post-mortem examination has been called for, one can only record facts and form conjectures. Possibly some contributor to THE LANCET may be reminded of a similar case, where a post-mortem examination has made patent the cause of such a peculiar sequence to the presence of stone in the bladder.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Treatment of Varix.—Extirpation of Larynx for Malignant Disease.—Intra-cranial Disease, involving several Cranial Nerves.

THE ordinary meeting of this Society was held on the 25th ult., J. Lister, Esq., F.R.S., President, in the chair. A case of tabes dorsalis, in which the right sciatic nerve had been stretched three months ago by Mr. Adams, was shown by Dr. Buzzard.

Mr. J. R. A. DOUGLAS read a paper on cases of Varix, treated by a new instrument invented by him for obliterating the veins, called a vein brooch, which produces flat pressure on varicose veins and varicocele by means of a horn or steel spatula, with a grooved needle riveted at the eye end and fastened at the point. It is passed under the vein by a catch like a brooch or safety-pin, gives very little pain, and, unlike the old torsion of wire or silk ligature, produces no constitutional disturbance, but obliterates the vein with certainty and without subcutaneous division. He referred to another extremely simple instrument, invented by A. Baird Douglas. A flat-pointed steel pin passed to the head through a disc of india-rubber, then through the edges, and then through another disc of rubber holding the edges of a wound perfectly and tightly together without other ligature. The extreme tenacity of the rubbers prevents slipping, and can be passed on wire without moving in case of ruptured perineum, vesico-vaginal fistula, &c. Wounds heal by first intention, as the soft rubbers prevent the pin ulcerating out, as wire and silk ligatures do with a knot. These instruments are made by Messrs. Maw, Son, and Thompson. He claimed for the invention simplicity, easy application and removal, readiness of application, little pain or constitutional disturbance, and obliteration of vein. Notes of five cases were read. 1. A police-constable, aged forty-three, unfitted for duty in consequence of weakness and pain in right leg, due to varicose veins. Two brooches were applied under the vein in the thigh, which two days after was divided subcutaneously. The symptoms entirely disappeared. 2. A police-constable aged thirty-eight had diffused varix below knee for six years, and twice ulcerated leg. The saphena vein inside and under knee was large and full, and below a large bunch of varicose veins and open ulcer above ankle. One brooch was passed under large vein, which was not divided. Ulcer healed during the time he was in bed. 3. Man disqualified for militia on account of varicose veins. Operated upon with one brooch, and he was well in thirteen days. 4. Private patient aged forty, suffered with varicose veins and ulcer above ankle. The saphena vein was grasped, and the grooved needle of a horn brooch passed behind it. The brooch was removed the fifth day, and the varix disappeared. 5. A private in the Hussars, the subject of varicocele on left side, preventing him from riding, and unfitting him for service. The bunch of veins was grasped, and two horn and spring brooches passed behind them. They were removed in eight days, and the man recovered completely.—Mr. GOULD observed that in a case of amputation of the hip reported to the Society two years ago he employed suture pins with vulcanite pad at their head, and a soft rubber pad which was passed over the pin when *in situ*, a device similar to that of Mr. Douglas. He had since used them in other cases, and in one case intermediary hæmorrhage was checked by simply readjusting the rubber pad.—The PRESIDENT said the efficacy of the "brooches," which pressed only on one part of a vein in curing extensive varix of the lower limb was striking, and hardly to be anticipated.

Dr. WHIPHAM and Mr. PICK communicated a case of Extirpation of the Larynx for a Growth originally affecting the left ventricular band and vocal cord, which subsequently involved the whole larynx. The patient, a commercial traveller, aged thirty-nine, consulted Dr. Whipham on May 27th, 1876, on account of huskiness and a constant desire "to clear the throat," which had come on suddenly and without apparent cause. He had been previously free from all throat affection, and there was no history of syphilis. The man was very nervous, and it was not till June 8th that a view of the larynx was obtained. It was then found that a warty-looking growth rather larger than a pea arose from the anterior part of the left ventricular band and vocal cord. After repeated examination and the passage of brushes into the larynx, with a view of preparing the patient for operation, his nervousness was so far under control on July 29th that two small portions were removed by evulsion, with great relief to the huskiness. The case was constantly under observation, but no further operative interference was required until March 3rd, 1877, when three pieces of the tumour (which microscopically presented for the most part the appearance of papilloma, but in which at one or two spots there appeared to be a tendency to the production of epithelial cells) were removed by the forceps. The whole of the warty portion was removed at this time, but the vocal was thickened generally; the voice recovered tone to a great extent. Subsequently, however, it was found necessary to apply the forceps to a recurrence of the growth on several occasions—viz., June 16th, 1877; January 5th, 1878; March 23rd, 1878; April 19th, 1878; December 31st, 1878. Early in 1879 the patient had a severe attack of catarrhal laryngitis, and on June 23rd in that year he complained of having lately suffered from great dyspnœa, with tenderness over the thyroid cartilage and some external swelling in this situation. He was admitted into St. George's, and in the course of the following six weeks several pieces of the tumour were removed. Again in October, 1879, a large piece was taken from the larynx. By March, 1880, a great change had occurred in the state of the parts; the growth involved the whole ventricular band and vocal cord; the left ala of the thyroid cartilage was pushed outwards, and was tender; dyspnœa being at times urgent. Towards the end of April the dyspnœa threatened suffocation, and Mr. Pick, after examining the patient, performed tracheotomy, from which the recovery was perfect. During the next six months the disease progressed rapidly, the whole larynx being involved by the middle of October, when a large lobulated mass was felt in the position of the left ala of the thyroid cartilage. In the early part of November, 1880, some hæmorrhage occurred through the tube, and at the end of the year he was readmitted into hospital with a view to the performance of some operation. Shortly after his readmission this hæmorrhage recurred rather freely. After consultation with his colleagues on the previous day, Mr. Pick proceeded to extirpate the larynx. Having introduced a tampon cannula, Mr. Pick made an incision on January 16th, 1881, two and a half inches in length in the median line of the neck, and a second incision at right angles to it across the middle of the thyroid cartilage. On reflecting the skin the growth was found to involve the left ala of the cartilage. The thyroid cartilage was then divided vertically in the median line, and the two halves separated, when the whole larynx was found occluded by the growth. The left ala was removed, and subsequently the right also. The cricoid, with the remains of the arytenoids, were then freed from their attachments, and removed, and finally the epiglottis, which was involved in the disease, was cut away. The wound was carefully explored, and all traces of the growth as far as possible were removed. No vessel required ligature. The operation occupied three-quarters of an hour, and the patient was not much exhausted at its close. The wound was plugged with sponges. Slight hæmorrhage occurred after the operation, which was arrested by the introduction of an additional sponge. Nutrient enemata were ordered every four hours, and for the first two days the patient's progress was satisfactory. On the third day, however, his temperature rose to 103·2° F., and his skin became dry; his pulse ran up to 142. On the fourth day he complained of severe pain about the ensiform cartilage; his expression became anxious. Rapid exhaustion set in, and he died on the morning of the fifth day after the operation. At the autopsy, right pleurisy and pericarditis, presumably pyæmic, were the chief lesions found. Among the many points of interest in the case, the following were brought before the notice of the Society:—1st. That for three years the microscopic appearances of the growth were for the most part those of papilloma. 2nd. That the duration of the disease (four years) was rather in favour of its having been an innocent growth in the earlier stages, although microscopic examination showed that, even at the onset, there was, in one or two places, a tendency to epithelial proliferation. 3rd. That the above facts, and the limitation of the growth to the larynx, were favourable to the success of the operation of extirpation. 4th. That if the operation had been undertaken as soon as the malignant aspect of the disease became manifest success might have been the result. 5th. That the plan of dividing the thyroid cartilage and removing each half separately is preferable to the method adopted by Dr. Foulis of removing the larynx entire, and for these reasons: (1) that by separation of the alæ a good view of the extent of the disease is obtained at an early period of the operation; and (2) there appears to be less danger of wounding important structures.—Dr. SÉMON was gratified that Mr. Pick had found his modification of Trendlenberg's tampon cannula useful; and he drew attention to the liability to dyspnœa being caused by over-inflation of the tampon. This occurred in a case of thyrotomy he had recorded, and was attributed by him to pressure upon the tracheal branches of the vagus nerve. Similar attacks occurred in two cases by Dr. Bosworth, and also in one by an Italian surgeon, and another by an English surgeon. The dyspnœa at once ceased on allowing some of the air to escape from the tampon. In Mr. Pick's case there could be no doubt that the disease was epitheliomatous at the time of operation. Extirpation of the larynx was not necessary for papillomata, which could be removed by endolaryngeal operation or by thyrotomy. He believed that for a simple growth to become malignant there must be a constitutional tendency to malignant degeneration, which would manifest itself whether the growth had been interfered with or not. To show what may be done by persistent endolaryngeal operation, obviating recourse to the formidable operation of extirpation, he quoted a case recently published in the *Berlin. Klin. Wochenschrift.* It was a child, eleven years old, in whom a papillomatous growth had been removed by thyrotomy, subthyroid laryngotomy, and thyrotomy again with invariable recurrence; extirpation of the larynx was advised but declined; and for six months Dr. Bucher persistently treated it by endo-laryngeal methods, so that he succeeded in completely removing the growth. Fifteen months later the child was free from the growth. In fact, papillomatous disease does not give any indication for extirpation of the larynx.—Mr. PICK agreed that extirpation was not called for so long as the growth could be removed by the forceps. In this case it would have been better to remove the ala of the thyroid when the tracheotomy was done, for the growth had already perforated the cartilage.

Mr. SPENCER WATSON read a case of Intra-cranial Disease involving several Cranial Nerves. A married woman thirty-six years of age, who had suffered from miscarriages and a severe flooding after a confinement, was seized with severe neuralgic pain of the left side of the face, with loss of sensation in the same side of the face and ptosis, loss of smell, taste, and hearing of the same side. After the symptoms had persisted seven months twenty-grain doses of iodide of potassium were given three times a day, with the effect of rapidly relieving the pain in the parts and restoring smell, taste, and hearing, and partially restoring the paralysed upper lid and the paralysed ocular muscles. There was a relapse after the relief had persisted for more than a month, and the condition of the patient was still unsatisfactory at the last time of seeing her. The amount of iodide of potassium taken in a continuous course of thirty-one days' duration was between three and a half and four ounces.—Dr. BUZZARD said the case was one not uncommon in syphilis, where frequently several cranial nerves become involved. Sometimes with peripheral affection of the fifth there is also affection of the portio dura. The ulceration of the cornea in such cases is attributed by some to disturbed trophic influence; by others to the irritation of foreign bodies on the insensitive conjunctiva. In this case the cornea was not ulcerated, and it was interesting to find that the third nerve was paralysed, the ptosis probably preserving the cornea from irritation. He thought the iodide should be pushed, in spite of symptoms of iodism, and suggested that mercury should also be given. There seemed no doubt of the syphilitic nature of the disease.—Dr. WHIPHAM mentioned that iodism may often be prevented by freely diluting the mixture containing the iodide.—The PRESIDENT thought the iodide should be pushed farther. He was not aware of the fact stated by Dr. Whipham, and would like to know if the large doses of the drug acted when diluted as beneficially as without dilution.—Dr. WHIPHAM said that so far as his experience went the same beneficial effects were produced without the ill effects of iodism.—Dr. POWELL corroborated Dr. Whipham's statement. The value of diluting the iodide was taught many years ago by Dr. Hare; and his own (Dr. Powell's) impression was that it increased the efficacy of the salt.—Dr. CROCKER said that the troublesome coryza could be controlled by small doses of strychnia, a fact pointed out to him by Dr. Gilchrist. That arsenic will control the eruptions due to iodism was well known.—Mr. SPENCER WATSON said that he intended to continue the treatment, and to again give mercury (which was for a time given). The relief from pain produced by the iodide was very great. He believed corneal ulceration in paralysis of the fifth was simply due to irritation by foreign bodies; it could be prevented by simply keeping the eyelid closed, and in this case the ptosis acted beneficially. At the same time the turbidity of the vitreous pointed to trophic disturbance.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

Cases of Disease of the Nose.—Traumatic Rupture of the Perineum.—Endocarditis with Embolism.—Opaque Optic Nerve Fibres.

AT the meeting on March 21st, Dr. Broadbent, President, in the chair,

Mr. SPENCER WATSON read notes of two cases of Disease of the Nose, which he could not place under any ordinary category. The first was that of a man who had suffered from pain in the nose since 1869. He was married, and had a family, but contracted syphilis twenty years ago. The nose was red as if from acne, but the nostrils were free in front and behind; the sense of smell was good, but the throat and fauces were congested. There were paroxysms of pain, so severe that Mr. Watson at first thought he had to deal with a case of hypochondriasis. There was no periostitis. The syphilitic history led to the prescription of iodide of potassium in full doses, and a speedy cure resulted. The second case was that of a clergyman, who for the two previous years had been subject to congestion and redness of the nose. There was no history of gout or rheumatism. The patient had lived for years in Demerara, and was of regular habits. He suffered, however, from habitual constipation. The attacks of redness came on at uncertain times. The administration of Carlsbad salts, and the application of ice to the nose did good; dry cupping was useful, and tobacco-snuffing lent considerable aid. Dr. Graves reports a somewhat similar case, not regarded as of gouty nature. He thought it was of a nervous character, and resembled hysteria.—The PRESIDENT regarded the first case as of undoubtedly syphilitic origin; the second was most probably a reflex nervous phenomenon.—Dr. ROUTH thought the second case comparable to one of congestion, such as is frequently followed by copious nasal discharges, of which he had seen several instances.—Mr. ED. OWEN thought the second case dependent on the chronic constipation; it might be simply of dyspeptic origin. He referred to the fact of nasal irritation in children suffering from intestinal worms.—Mr. WATSON, in reply, said that the snuff-taking produced no irritation, but simply kept up a slight discharge of mucus, which, in the dry condition, gave relief. The intestinal condition may have had some influence.

Dr. WYNN WILLIAMS read notes of a case of Traumatic Rupture of the Perineum in a girl aged five years, who had been impaled on the broken bar of an iron bedstead. The sphincter ani was completely torn through, and the mucous membrane was prolapsed. He proceeded at once to operative measures, paring the edges of the wound and performing the ordinary operation for rupture of the perineum. The result was perfect, and the girl, who is now some years older, has perfect control over the sphincter. In reply to Mr. Gould, he said that others thought she would have recovered the use of the sphincter, as she grew older, without operation.

Dr. GILBART SMITH read notes of a case of Acute Endocarditis with Embolism. F. R——, aged fourteen, admitted into the London Hospital on Feb. 8th. At the age of twelve she had rheumatic fever, but up to one month before admission was quite well, except for headache, which came on at intervals, with palpitation on exertion. One month before admission she began to suffer from vomiting after meals and headache; so that she was compelled to take to her bed fourteen days before. Five days previously she began to see badly, had difficulty in opening and shutting her eyes, and a profuse watery discharge, with scalding, came on. When admitted she was poorly nourished and suffered from conjunctivitis. The heart's apex beat in the fifth interspace below the nipple; there was a systolic bruit at apex, and a double basic murmur. Temperature 101·5°; pulse 96; respiration 36; tongue dry and furred; sordes on lips. During her stay in hospital her mental condition varied; she was generally irrational and delirious, with insomnia and headache. There was rapid emaciation; great pain in legs, preceded by blocking first of the vessels of right leg then of left. The left foot became gangrenous, and petechiæ occurred on the legs and lower part of abdomen. The eyeballs became prominent, and embolism of retinal vessels was also inferred, though this could not be verified owing to the condition of the media. There was increase of the splenic area and tenderness in that region. The pulse towards the end became very rapid, from 132 to 162; respiration frequent, generally about 48. Temperature fluctuated between 105·6° and 99°; generally being 101° to 104°. Albuminuria appeared ten days before death.—Post-mortem: Great wasting; gangrene of left foot; lungs normal; heart enlarged; large masses of vegetations springing from bases of aortic valves, extending over anterior mitral cusp; infarctions of spleen and left kidney; right kidney and liver congested; œdema of brain, wasting of convolutions. Dr. Gilbart Smith raised the question whether the symptoms were not those of a septicæmia rather than rheumatism, and pointed out that the form of verrucose endocarditis here present was not to be confounded with ulceritive or diphtheritic endocarditis, which is more usually accompanied by infective processes, leading to a pyæmic or typhoid condition. The inflammation of the eyes, with the prominence of the eyeballs, were considered to be due to embolism of the ophthalmic arteries, and consequent engorged state of the veins. Mr. Adams considered the ophthalmitis to be essentially pyæmic. The plugging of the arteries of the lower limbs was attributed to embolism, aided by the cardiac weakness; and the diagnostic significance of retinal and cutaneous hæmorrhages in valvular disease, with varying murmurs, was also alluded to.—Dr. MACDONAGH inquired if the case was one of endocarditis with rheumatic symptoms.—Dr. DOWSE asked if any thrombi were met with in the pulmonary artery or heart.—The PRESIDENT remarked, that in ulcerative endocarditis there would be no large embolisms, but more probably capillary emboli. The ophthalmic condition was of some interest. Had there been any variation in the pitch of the cardiac sounds?—Dr. GILBART SMITH, in reply, said that there was a distinct history of rheumatic fever and heart disease two years ago. He thought the emboli started from a chronic endocarditis, and, reaching the eye, had initiated a general septicæmia with acute endocarditis. The variation in the murmurs was a great help in diagnosis.

Mr. WORDSWORTH exhibited a remarkable case of Opaque Optic Nerve Fibres in a boy of about five years of age. The condition was confined to the left eye, and was of course congenital. On entering the eye the nerve fibres expanded into a dense white membrane, which completely surrounded the optic disc and extended irregularly in the fundis oculi for a distance of several diameters of the optic disc, and gradually shaded off into the transparent retina. Only slight indications of the limits of the optic entrance were perceptible, and the vessels passing through the nerve became obscured by the expanded fibre on leaving the limits of the nerve area, and were completely hidden until they emerged beyond the opaque fibre. The eye was myopic one-third to one-fourth; sight was very imperfect, and the "blind spot" of large size.

The Society then adjourned.

CAMBRIDGE MEDICAL SOCIETY.

Terebene as an application to Wounds.—Truss padded with India-rubber Sponge.—Large Gall-stone; how it may have escaped from Gall-bladder.—Scirrhous Cancer of the Male Breast; Eczema of the Nipple.

AT the meeting of the Society on Friday, March 4th, Mr. James Carter, F.R.C.S., Vice-President, in the chair,

Mr. STEAR advocated the Use of a Mixture of Terebene and Olive Oil in preference to Carbolised Oil as an application to Wounds, and more especially in cases of cancer and other foul-smelling sores. It was hardly inferior to carbolic acid as a disinfectant and deodoriser, and it had the advantage of being non-poisonous, of possessing an ozonising property, and of being pleasant to the smell. He showed also a "Salmon and Ody" truss, the pad of which was fitted with a covering of india-rubber sponge. The idea was taken from the practice of saddlers to use the same substance as a padding for riding-saddles and horse-collars, and it was found to prevent chafing.

Dr. LATHAM showed the broken pieces of a large Gall-stone, originally measuring 1⅛ in. in diameter, globular in shape, and weighing 104 grains, which had been passed along with a small facetted gall-stone, by a woman in the hospital, admitted for obstruction of the bowels. There was no history of pain arising from gall-stones passing into the bowel. The large globular mass seemed to be too large to have passed by the cyst and common bile-duct. Thinking that it might be an entolith, he had examined a portion of it for cholestearin (in the usual way, by extracting with absolute alcohol and filtering when hot), and he showed a test-tube containing a quantity of cholestearin scales, and the same under the microscope. The outer shell of the stone contained a considerable quantity of brown colour, and a part of the central mass was obviously crystalline. His theory was that it was a true gall-stone; that it had passed by a fistulous opening through the fundus of the gall-bladder into the adherent intestine (transverse colon); and that the chronic peritoneal inflammation which would have occurred in due course was the cause of the obstruction of the bowels.

Dr. HUMPHRY showed a large Cancer of the Breast, of typical scirrhous texture, which he had removed, along with a cluster of scirrhous axillary glands, from a man aged sixty-three. The tumour was a large indurated, heavy mass, three inches in diameter; its thickness, after removal, was found to be upwards of an inch and a half. The nipple corresponded to the centre of it, and was retracted, and the skin was adherent all round. Indurated lymphatic glands in the axilla could be felt. The patient had observed the tumour for about one year; no history of injury. Eczema of the nipple had existed both on the affected side and on the sound breast; the patient spoke of it as "scabbing about the nipple," which he picked with his fingers. His colleague, Mr. Wherry, had, at a former period, seen the eczema on both nipples; that on the sound side looked as if an excess of secretion had escaped and dried on the skin. The formation of cancer in the male breast was itself a puzzle. It was remarkable that the male breast should persist at all, and its chief interest to us is that now and then it becomes the seat of cancer. As to the operation, he had removed the tumour freely; there was much hæmorrhage, and feverish symptoms followed, but the patient was now doing well. He thought it a good rule, if there were no nodules in the adjacent skin, to make the incision go as wide of the cancer as possible. In this case there was a large wound, and he would formerly have allowed a large suppurating and granulating surface to form, in the belief that such slow healing reduced the liability to return of the disease. But more recently he had himself adopted the practice of Listerism, under which the wounds healed quickly, and it had not appeared that the liability to recurrence was greater after rapid healing than after suppuration and granulation. It was said that surgeons, as they advanced in life, became more reluctant to remove cancers, but he had become on the whole more willing to remove them, and to remove them freely. The operation was now attended with little or no pain, and with little danger, and if there was a fair prospect of removing the entire visibly diseased structure, he thought the operation should always be undertaken.—Dr. CREIGHTON, referring to the occurrence of cancer in the male breast, remarked that there were hardly any observations on the extent to which the structure of the breast persisted in the male after puberty. Its extent probably varied very much among individuals, as, indeed, the casual observations of the dissecting-room showed; and he was inclined to think that a predisposing cause of the formation of a cancer in the male breast was the persistence of a considerable amount (beyond the average) of breast structure and of corresponding functional tendencies.

Mr. SHANN brought forward a case of Floating Kidney in a woman.

Mr. WHERRY showed a fresh specimen of Scrofulous Testicle removed by operation.

Reviews and Notices of Books.

The Student's Guide to the Diseases of Women. By A. L. GALABIN, M.D. London: J. and A. Churchill.

WHEN reviewing the first edition of this work we pointed out its many excellences as well as some features that appeared to us to detract from its value. We can say that in the present edition the former have been increased and the latter lessened. In the present issue additions of new material and modifications in what was in the previous one have been made. Among the modifications we find less heroic treatment advised for certain cases of disordered function and imperfect development; even the treatment now recommended, however, is, in our view, far too active and frequent; for although we have no doubt that Dr. Galabin has a full and lively sense of the fact that there are cases of imperfect development and disordered function which it would be almost if not quite criminal to treat by local means, yet he does not convey this fact to the reader with that degree of clearness which is called for. Among the additions we notice the portion treating of the relative importance of displacements. The author having stated that there are two opposite views held with regard to this subject, says:—"The truth would seem to lie in the mean between these extreme opinions." The process of "splitting the difference" or "striking the mean" may be a good rough-and-ready way of arriving at an approximation to the truth in questions surrounded by passion and prejudice, but when the question is one of scientific evidence the method does not apply. Had Dr. Galabin given a brief summary of the evidence put forward for and against the importance of displacements, he would have done the student a permanent service, and had he, in addition, pointed out what is necessary to be done in order to establish the importance of displacements upon a solid basis, he would have armed the student with a means of estimating for himself the value of evidence whose quantity, whatever its quality may be, is almost measureless. We trust that in the next edition Dr. Galabin will see his way to carry out the above suggestion, and thereby enhance the worth of his already valuable work.

The Cure of Rupture, Reducible and Irreducible, also of Varicocele and Hydrocele, by New Methods. By GEORGE HEATON, M.D. Arranged and Edited by J. HENRY DAVENPORT, A.M., M.D. Harvard. Boston: H. O. Houghton and Co.

SOME weeks ago we noticed a book on this same subject by Dr. J. H. Warren, who indeed merely followed in the footsteps of Dr. Heaton. It will be remembered by some of our readers that Dr. Heaton visited this country several years ago, and demonstrated his operation for the radical cure of hernia. But shortly after his return to America he brought considerable discredit upon himself by keeping his practice secret, and it was only just before his death that he made it public. His operation for the cure of reducible hernia is fully described in the work before us. It consisted in injecting extract of quercus alba into the hernial canal outside the peritoneal sac, the object being to excite a very mild degree of inflammation or "irritation" in the tendons and fasciæ around the sac which form the barrier to the production of hernia, and so lead to their contraction. It is stated that, although the operation had been practised "many hundreds of times," it has never been attended with fatal results or complications exciting anxiety, and that when it fails to cure it usually gives such relief that a light simple truss is sufficient for the prevention of the recurrence of the hernial protrusion. A hundred and forty cases are briefly recorded in support of these assertions. Dr. Heaton was also in the habit of treating irreducible herniæ with more energy than is customary, for he appears to have always attempted to make them reducible. If taxis, repeated, and aided by position and anæsthetics, failed, he either broke down the adhesions with his finger pressed in through the skin, or enlarged the rings by a tenotome, or, as a last resource, opened the sac, freely divided adhesions, removed omentum, and reduced the intestine. Several cases thus treated are recorded, and Dr. Heaton asserts that these measures also never lead to a fatal result. Probably this subject will excite more sympathy than that of the cure of hernia by astringent injection, and it certainly is one that deserves more general attention than it has hitherto received. It is probable that the mortality attending operations upon strangulated hernia and inflamed peritoneum has prevented the adoption of measures in a great degree devoid of the special dangers of the former. Among others, Mr. Lister has recorded cases of irreducible hernia cured by operation, and we doubt not that this will be one of the most useful applications of intra-peritoneal surgery.

Transcendental Physics. An Account of Experimental Investigations from the Scientific Treatises of J. C. F. ZÖLLNER. Translated by C. C. MASSEY. London: W. H. Harrison. 1880.

Psychic Facts. A Selection from the Writings of various Authors on Psychical Phenomena. Edited by W. H. HARRISON. London: W. H. Harrison. 1880.

Animal Magnetism. Physiological Observations by RUDOLF HEIDENHAIN, M.D. Translated from the Fourth German Edition by L. C. Wooldridge, B.Sc. London: C. Kegan Paul and Co. 1880.

IT must not be supposed that the works above named are equally deserving of thoughtful study. The first two are in their way curiosities of literature, and of that pseudo-philosophy which has sprung up from the vagaries of the so-called spiritualist. The "experimental investigations" of Dr. Zöllner are chiefly directed to attempt a physical explanation of the clever legerdemain of the notorious Dr. Slade, who is held up for pity as one persecuted by the narrow spite of English scientists, to find more willing investigators in Germany and Russia. This book and the one next named may be said to embody the chief doctrines of "psychic force."

It is hardly fair, perhaps, to include Professor Heidenhain's *brochure* with the foregoing, for it is a work of a wholly different stamp, dealing with a different though cognate subject. The facts of hypnotism, spontaneous or induced, are daily receiving more attention than was vouchsafed to them a generation ago, when they were so mingled with deceit and trickery as to be for a time obscured and shunned. Professor Heidenhain is well known as an accomplished physiologist, and his writings have no need of the *imprimatur* of Mr. Romanes, who has edited this translation of his lecture, and who has already made known the results of Professor Heidenhain's work in an article in the *Nineteenth Century.* The author believes that the hypothesis that the "cause of the phenomena of hypnotism lies in the inhibition of the activity of the ganglia cells of the cerebral cortex" is a tenable one, "such inhibition being brought about by gentle prolonged stimulation of the sensory nerves of the face or of the auditory or optic nerve"; and he maintains that such an explanation has only been possible since our knowledge of nerve-function has been perfected by means of experimental physiology. In a recent contribution to our columns M. Richet has spoken in the same sense, and has advocated the further study of hypnotic phenomena as a means of increasing our knowledge of the mechanism of cerebral action.

A SALESMAN of Derby has been fined £130 and costs for exposing for sale meat that was unfit for human food.

THE CORNU AND CHOROID PLEXUS OF THE FOURTH VENTRICLE OF THE BRAIN.

To the Editor of THE LANCET.

SIR,—Whilst reading the report in your valuable journal of Dr. Moxon's highly interesting Croonian Lecture on the "Influence of the Circulation on the Nervous System," my attention was arrested by the following statement:—"Our anatomical works all speak of a sort of pouch from the side of the fourth ventricle, but none of them point out that this pouch is stuffed very full of tufts of bloodvessels in the form of choroid plexus." This is clearly an oversight on the part of the learned lecturer; for instance, distinct mention is made of this vascular fringe in Quain's Anatomy, vol. ii., p. 513, eighth edition; also by Professor Turner in his Introduction to Human Anatomy (p. 261). The statement is to this effect: Key and Retzius have recently described two additional communications, one on each side of the anterior part of the floor of the ventricle. Through these openings *vascular folds* of pia mater, named the *choroid plexuses* of the fourth ventricle, enter its cavity. These openings and choroid plexuses are well known to the students of the Middlesex Hospital, and are constantly demonstrated to them in the dissecting-room; indeed, there is a preparation to show this very point in the museum of the hospital. With regard to the vascularity of this plexus I was totally ignorant until the summer of 1879. At that time I was fortunate enough to obtain a successful injection of its villi in a fœtus at term. The injection was performed before the natural heat had abated, and proved, as one suspected, that the plexus was intensely vascular. I have still a specimen of it in my possession; it shows, in addition to the vessels, the delicate hyaline investment which covers the tuft of the capillaries like a mantle. The notion that I had fallen upon something novel was soon dispelled, for upon going more minutely into the literature of the subject the statements in Quain and Turner's works were quite sufficient to set the thing at rest. I should not have thought anything more about making this matter public but for the observation of Dr. Moxon with regard to them in his lecture.

I am, Sir, yours truly,
J. B. SUTTON,
Assistant Demonstrator of Anatomy,
Middlesex Hospital.
March 28th, 1881.

"HOMŒOPATHY OR—WHAT?"

To the Editor of THE LANCET.

SIR,—We, both Liberals and Conservatives, have heard with great regret of the illness of Lord Beaconsfield, and I am sure most of us have observed with pleasure that the Queen had suggested that further advice should be called in. This suggestion, as we know, was carried out, and the skill of Dr. Quain was soon placed at the disposal of the Earl. In the account given in to-day's *Times* of the consultation between the two eminent advisers of his lordship, it states, that "Dr. Quain expressed his approval of the treatment adopted by Dr. Kidd." Now, Sir, I was always under the impression that Dr. Kidd was a homœopath—indeed, the leading spirit of homœopathy in London; and that Dr. Quain was an allopath. How, then, are we to reconcile this agreement in treatment? "Is Saul also among the prophets?" Has Dr. Kidd altered the tenour of his ways, and gone over to the old school? Or does he *profess* homœopathy and *practise* allopathy? Or does he reserve homœopathy for his less eminent patients? Or has Dr. Quain—but no, the thought is too dreadful!

Yours faithfully,
A. GEORGE BATEMAN (Allopath).
Canonbury-lane, March 30th, 1881.

To the Editor of THE LANCET.

SIR,—In to-day's paper I see that Dr. Quain is reported to have met Dr. Kidd in consultation on the case of Lord Beaconsfield, and, further, that he approved of the latter's treatment. Is Dr. Quain aware that Dr. Kidd's name is in the Homœopathic Directory for this year, and that he was lately on the Council of the London School of Homœopathy? And what treatment from a professed homœopath could Dr. Quain endorse?—I am, Sir, yours obediently,

March 30th, 1881 JUNIUS.

THE LANCET.

LONDON: SATURDAY, APRIL 2, 1881.

THOSE who watch the progress of medical science can hardly fail to observe how it is influenced by the realistic tendency of modern thought, and to see that, largely under the guidance of German teaching, it has become essentially objective. General views, however well supported by analogy and logical deduction, have little value in comparison with that which is demonstrable, as if morbid anatomy, the scalpel, and the microscope were the only agents by which the problems of disease could be solved. Humoralism has given place to solidism, and the prevailing tendency is to localisation of disease at the expense of the importance once so freely ascribed to "blood conditions," "constitutional states," and "diatheses." To the older members of the profession it is indeed novel to hear, for instance, that cancer is a local affection, with "perhaps" and "in part" a constitutional origin, and that, as we are now taught, the diseased lung in a considerable proportion of the cases of phthisis is no longer to be regarded as the local outcome of a morbid constitutional state or diathesis, but as essentially a local disease, only differing from ordinary pneumonia in the fact that it involves the alveolar walls of the air cells as well as their cavities, and that we should regard the general symptoms and constitutional consequences as but the result of this local disease.

Under these circumstances it may be well for a moment to recall attention to the typical morbid states of the blood and of its germs, and at the same time see how far this modern pathology tends to support or set aside the germ theory generally. We would premise that by blood we mean not only the actual circulating blood, but its tributaries also, and that by the term "germ theory," which has, we consider, lost much in interest and attention by the various significations with which it has been employed, we mean the affirmation that several morbid states of the blood and many diseases of structure are caused by the action of germs: and as in some instances these are introduced from without, and are therefore foreign to the body they invade, whilst in others there is reason to believe that they are modifications of the organisms of the body itself, we shall treat of them separately, as respectively "disease germs" and "diseased germs."

The simplest and most familiar examples of blood diseases induced by the introduction of germs from without are supplied by the exanthemata. It is unnecessary to offer proofs that these are blood diseases and propagated by infection or contagion, whilst investigation has now demonstrated that the contagium in each, on its introduction, produces the particular disease of which it is the special cause, with all its specific morbid phenomena; that whilst so doing, and in its passage through the body, it manifests vital characters, especially that it increases and multiplies with intense fecundity; that it does not pass with fluid on filtering, and must therefore be particulate—in fact, that it must be a germ, and eminently endowed with germinal power.

Equally striking — in many respects more striking — examples are afforded by the allied specific fevers, inasmuch as in these generally more distinct evidence of the actual presence of the germs in the blood is shown, in that the disease itself is inoculable by blood of an infected subject. We take the exanthemata and specific fevers as our first examples, however, not simply because they and their phenomena are so familiar to us, and they have therefore received special notice and been the subjects of unusual observation and research, but because they afford us the opportunity of pointing out some remarkably interesting variations in the nature and mode of operation of the contagia or germs themselves. It must be familiar to all who have studied or attempted classification, how, whether in the animal or vegetable world, or in the case of diseases, the groups seem to arrange in circles, each radiating from a typical centre to a circumference at which it touches those of other circles most nearly allied. So it is with the exanthemata and specific fevers. From a central example—say small-pox, manifesting contagion and infection, and the immunity which one attack gives in an intense degree,—we pass gradually to those that possess these qualities less markedly; to those that are infectious but not inoculable, and to those that are inoculable but not infectious, till we reach those which are neither inoculable, nor infectious, nor prophylactic. So exactly with germ cells. Some seem to be imbibed from the air or carried into the interior with food, some to be inoculable by contact with unbroken tissues and delicate mucous membrane, some seem to require direct contact with the blood or denuded surfaces, whilst in some, again, inoculation with the blood of the infected patient is all potent, and in others only with the germs supplied from the special foci through which the poison seems to be eliminated, which facts have now been repeatedly demonstrated by experiment. Whether the germs thus introduced are of animal or vegetable nature it is impossible to say. The researches of CHAUVEAU and BURDON-SANDERSON, of OBERMEIER and MEIGART, and especially of Dr. KLEIN, have shown that peculiar organisms are met with, in several of these diseases, in such situations and under such conditions as to be presumably the actual disease germs; and that these peculiar organisms are, judging by some of their characters, of vegetable and fungous nature. It may be that there are vegetable germs as well as animal germs of disease; nor is there anything very imaginative in the supposition that this very difference in their nature may afford the reason why their actions and resultant morbid states so widely differ; why intermittent fever, for instance, is neither inoculable nor contagious, for it would seem but natural that whilst ague and others of the non-infectious class should be caused by organisms of vegetable origin, those which are communicated through infected blood and by contact only with very delicate or denuded surfaces, should be animal germs. There is moreover some evidence of the convertibility of these organisms from one recognised form to another, according to circumstances. BUCHNER of Munich has, by very ingeniously arranged experiments, succeeded in producing from the hay bacillus—which is incapable of growing in blood, by modifying the solutions in which it is cultivated and inducing it to form spores—a bacillus which, like the bacillus of anthrax, will not develop in hay infusions but will in blood, and which, possessing all the other properties, toxæmic and specific, of the bacillus of anthrax, gives rise on inoculation to all the conditions of anthrax—the splenic blood being peopled with the newly formed organisms, and communicating anthrax to healthy animals.

Some recent experiments of Wernich show that putrefaction, or the addition of putrefactive products to a cultivating solution containing bacteria, arrests their development and activity; whilst Pasteur, who has succeeded in cultivating the poison-germs which induce the peculiar disease of fowls called "fowl-cholera" in a neutralised solution of muscle, finds that these "microbia" are at once killed in yeast fluid, though the bacteria of "splenic fever" live and thrive in it. The repeated cultivation of these microbia, by impregnating fresh cultivating fluid with small portions of that previously stocked, in no way impairs their power, which is so intense that a minute portion of a drop invariably causes the disease, and death in two or three days, often in one; but it is quite possible to modify the potentiality of the solution, and so of its microbia, by variations in the mode of cultivation. Applying these observations, Pasteur shows that if he vaccinates, as he terms it, fowls with a solution of weak power, most of them live, and survive the disease, and, especially if again similarly vaccinated, may thereafter be inoculated with the most virulent solution with absolute impunity; in other words, that as vaccination renders the patient nearly always no longer susceptible to small-pox, so does "vaccination" with this weakened poison of fowl-cholera render the birds insusceptible of fowl-cholera disease.

These results of Wernich and Pasteur, moreover, seem to throw some light upon that special peculiarity of the exanthemata—that one attack generally gives an immunity for life; from those of Wernich we might infer that the poison affords its own antidote, in that as soon as it produces septic changes in the blood, these very changes destroy it; from those of Pasteur, that either the poison in its own elaboration produces some material which is inimical to its further development, or that it consumes all the special material requisite to its growth. To settle this question, Pasteur evaporated media in which the "microbion" had been fully developed until cultivation became impossible in the filtered liquid, and then added fresh cultivating fluid to the residuum, when development was at once fully re-established; the plain inference being that the arrest of development is not due to the introduction and presence of any deleterious matters, but to the abstraction of something necessary.

Passing now from the consideration of the specific fever, in respect to which we leave much unnoticed, we pause for a moment over the great examples of the day. To the clear philosophic deductions, the patient investigation and experimental research, and their masterly applications in practice, of Professor Lister we owe the grand results of antiseptic surgery. At home, abroad, no longer the recognised novelty, "Listerism" has become the recognised necessity of civilised surgery, for the voice of the surgical world proclaims its truth; and even those who hesitated to accept Professor Lister's theory and *rationale*—ascribing the success of his measures rather to extreme care and cleanliness—give willing testimony to the grand results of his practice. And what is antiseptic surgery but the rational application of the germ theory? Crowded wards, atmosphere loaded with the emanations from the sick, and from purulent and putrescent discharges, were seen to be the incentives to traumatic fever, pus formation, and delay in the healing of wounds. "Were septic elements more abundant in the surrounding media in such conditions?" Experiment proved they were. Means were adopted to destroy these and prevent their access to the wounded surfaces, and antiseptic surgery was at once a fact. So manifest, indeed, is the action of the presence of these germs that the surgeon is at once informed of the imperfection of his antiseptic measures by the rising temperature and commencing febrile excitement indicative of wasteful consumption and combustion, with pus formation, and can with certainty affirm that on inspecting the wound in such cases pus will be found, and with it, and in the dressings, the organisms supposed to be the septic germs in quantity. Could more striking evidence be imagined of the value of Professor Lister's antisepticism, or more direct of the importance of the action of disease-bearing germs? Space will not allow us to adduce similar evidence in respect of hospitalism, erysipelas, pyæmia, puerperal fever, &c., nor to do more than refer to the recent investigations of Dr. Greenfield on the woolsorter's disease, shown to be forms of malignant pustule and anthrax; the blood from the heart and spleen and juices of the bronchial glands of the patients being found to contain the typical bacilli, and inducing in other animals typical anthrax and death in a few hours; and especially to those of Tappeiner, who caused dogs to inhale in a lowered form, for a quarter of an hour daily, the sputa of chronic bronchitis; others the matter from a scrofulous gland; others, again, the sputa of a patient suffering from phthisis. In the first two sets of dogs no result followed; but in those made to inhale the sputa of phthisis, tubercles were found in the lungs whenever a period of nineteen to twenty-three days had been allowed for incubation—that is to say, before the dog was killed and examined. In this instance it seems obvious either that the sputa of phthisical patients must contain some contagium which induced the formation of tubercles in twenty-three days, or that the diseased cells, or germs imported from a phthisical lung by contact, induced, or by development and propagation formed, tubercle in a lung previously sound. The first assumption, in our present state of knowledge, seems unsupported; the second, *primâ facie* more probable, we think we shall be able to show receives material corroboration from the facts of "diseased germs," which we shall consider in another article.

SOONER or later we shall have to face the fact that it is no more possible to make a people healthy by Acts of Parliament than it is to render a nation religious, or inspire the aggregate intelligence of the multitude with sound principles of morality, by statutory enactments. In an economic sense, no doubt, the common-mind of a population is something distinct from the sum of its individual manifestations of consciousness; and therefore the nation, as a social organism, may reach a higher stage of development than has been attained by the average number of its members. This is particularly likely to be the happy result of intelligent progress in a country which has escaped the pestilent heresy that regards the *individual* instead of the *family* as the unit of the nation. Nevertheless, looking to the every-day workings of energy, of all kinds, in the midst of a community, and noting the operation of laws of association, action and reaction—as inexorable as the laws of Nature herself, though incomparably less rational,—in short, taking a "practical" view of this phase of sociology, it is impossible not to perceive that the final influence of legislation on progress can only be educational. It follows that the aim of the law-maker should be to formulate principles of policy rather than to define and control the details of personal conduct. There may be matters in respect to which the multitude need to be instructed through conduct, as children are taught, being trained to do certain acts, or to leave others undone, before they are in a position to understand the reason why; but affairs of this class and character cannot be numerous except in the earliest stages of a nation's history. The intelligence of a people rapidly outgrows this elementary grade of its development, and year by year the common-sense instinct more determinately asserts its right to be governed on obvious—that is, self-evident—principles. In patriarchal times, for example, it sufficed to enjoin the use of the mattock in carrying out an earth-system of sewage-disposal, to impose prohibitive measures of cleanliness, and even direct personal precautions, against disease, together with the avoidance of certain forms of flesh as food on account of the gross feeding of the animals from which it was derived, without in any instance attempting to popularise the wisdom and forethought by which these sound maxims of sanitary government were dictated. Later on, as general intelligence advanced, but attention was diverted from the simpler lines of social economy, public opinion broke from the bonds of tradition, and disowned and abandoned obligations and restrictions it failed to comprehend, and blindly and resentfully cast them aside as mere ceremonial observances incompatible with the higher grade of intellectual development to which it had attained. When this spirit set in, it ceased to be good statesmanship to regard the work of legislation in any other light than that of educational—or, as history has shown it to be, *re*-educationary—policy. The advanced sanitary system of the nineteenth century is little more than an extension and adaptation—not always an improvement upon the original form—of the system extant among the earliest communities, and specially embodied for the use of the people of Israel in the Mosaic code. The investigations of modern science tend to elucidate and enforce the provisions of the ancient system, rather than to justify the manner in which they have been set aside. Meanwhile the conditions of our social life and policy are, as we have said, such that it is only by such elucidation and intellectual enforcement the laws of health can now be effectively applied.

Sanitary reformers, in their enthusiasm, forget this practical phase of the question of progress. They argue, and declaim against Governments and the Legislature, as if the mere passing of a Bill through Parliament were a panacea for every ill to which a nation is heir. If this were the fact, the national health might be successfully promoted by agitation, and Acts of Parliament would come to be something more than legal facilities for the convenience of the well-disposed. As it is, the utmost service any statute can render the community is to afford such of its members as are in earnest an instrument to enforce the obligations set down. It is necessary—and the circumstances of the moment render it opportune—to call attention to this fact. It is true that we have large and very expensive organisations, such as the Local Government Department, the Metropolitan Asylums' Board, and Sanitary Authorities scattered over the country, which are especially constituted and maintained to set the law in motion and to quicken the dead letter of the Statute-book into a thing of life; but experience shows only too convincingly that incorporations of this class are apt to become inert, and in that event are sure to prove obstructive. Perhaps the most cranky and unworkable combination in the whole of the State machinery is the comparatively recent contrivance for local government purposes erected at Whitehall. To say that a deadlock has occurred is to understate the case. Not merely has progress been arrested, the wheels are hopelessly fixed, and the right honourable gentleman in charge of the apparatus is evidently at his wit's end and paralysed by dismay. It is not creditable that this should be so, but we cannot shut our eyes to the facts. The functions of the Local Government Board, so far as public health is concerned, are practically suspended. Perhaps two years hence, if we could only afford to wait, Mr. Dodson might have made up his mind in respect to matters of urgent concern. For the present, however, he is bewildered, and seeks refuge in "consideration," that common-place subterfuge of the mysterious and the incompetent. While Mr. Dodson is considering, small-pox may spread for want of means to isolate the sick, and the population may remain unprotected. The President of the Local Government Board is clearly unequal to his task—he has not the tact to rescue the rash but prematurely decrepit Asylums' Board from its legal troubles, as a stronger minister might easily do, and he has suffered himself to be over-ruled by the Treasury in respect to the question of funds to carry out the provisions of the Vaccination Acts, and to popularise, if he cannot enforce, revaccination. The supply of calf-lymph is probably not forthcoming simply because there were no funds available to defray the cost of providing it. Taking the situation as a whole it is humiliating, and we must add, disgraceful.

What is to be done? The only course open to those who have a practical interest in the cause of health, is to take the matter seriously in hand, and to do what the constituted authorities are, under diverse pretences, neglecting—namely, to put the law in motion. This is why we think it opportune to fall back on first principles, and to point out that, after all, it is to the *people* the appeal for energy must ultimately lie. The officials publicly charged with sanitary administration are not absolved from their duty, but the community is not doomed to tolerate preventable disease in its midst simply because its public servants neglect their plain duty. Self-help is possible, and self-help is the indispensable condition of complete success. The powers-that-be are inactive, but the principles embodied in our legal code are none the less effectual because they are not applied. Seeing that the issues involved in this question are those of life and death, it is strange that the public is not more deeply concerned. Small-pox is spreading, and the measures taken for the arrest of the epidemic are inadequate. In short, active precautions may now be said to have ceased, and the authorities answerable for this state of things are chiefly engrossed in paltry questions of responsibility and in mutual recrimination. If the community desires reform, it must take the matter into its own hands, and the inconveniences and sacrifices arising out of the situation will not have been endured without recompense if in the end it is brought forcibly home to the conscience of the nation, and learnt in the family circles of the population, that practical sanitation is an affair of Self-help.

THE annual report of the Inspector-General of Recruiting for the year 1880 affords a considerable amount of interesting information bearing upon the physical condition of the army and on the subject which has lately attracted so much attention—our boy recruits. The number of recruits who joined the service during the year was 25,622; this was 305 fewer than in 1879, but was more than sufficient to keep the force up to the establishment voted by Parliament for the year 1880-81, which was 178,430 men, while the actual number serving on the 1st of January, 1881, was 181,233. With a view, we presume, to facilitate recruiting, the standard of height for the infantry was lowered in June from 5 ft. 6 in. to 5ft. 5 in. During the year 42,668 recruits were primarily inspected, of whom 15,477 were rejected, being at the rate of 363 per 1000. This is considerably above the average, but the excess may probably be, to some extent, due to the opportunity presented by the large number of recruits for greater strictness in enforcing the requirements as to physical qualities. It is stated also that the regulations of the Army Medical Department for the examination of recruits were issued in a more complete form to all civil medical practitioners who were registered and authorised to examine recruits. That this, by inducing greater strictness on their part in the discharge of this important duty, may have contributed to the increased proportion of rejections, appears very probable from the fact that in the last Army Medical Department Report published—that for 1878—the proportion of recruits rejected on primary inspection by civil medical practitioners was only 149 per 1000, while that by army medical officers was 298. The means are not afforded in the report before us of ascertaining the practical result of this measure, for which we must wait until the Army Medical Department volume for 1880 is published.

With a view to show the effect of the present system of enlistment for short service upon the quality of the recruits, the Inspector-General has instituted a comparison as regards age, height, and weight, between those enlisted in 1874—the first complete year of the subdistrict system of recruiting—and those in 1879, the results for the latter having, we presume, been specially obtained from the Army Medical Department, as they have not yet appeared in any Blue-book. As regards age, the proportion of recruits under twenty amounted, in 1874, to 56 per cent., while in 1879 it was as low as 46 per cent. In 1865 the proportion under twenty was 55 per cent., so that it clearly appears there has been an improvement in 1879 under this head of about 10 per cent., as compared with previous periods. The proportion of recruits under 5 ft. 6 in. was 443 in 1874, while it was only 302 per 1000 in 1879; but the comparison as regards height is somewhat wanting in accuracy, for while the minimum for infantry was 5 ft. 5 in. throughout the first year, it was 5 ft. 6 in. during five months of the last. As the returns for 1879 are not yet published, we have not the means of making a strict comparison; it is, however, extremely probable that were we able to do so, the proportion under 5 ft. 6 in. would still be found lower in the latter year. On comparing the weight of the recruits enlisted in the two years, it appears that while in 1874 there were 434 per 1000 under 130 lb., in 1879 there were only 374 below that weight. There are no details given of the chest-measurements of the recruits, but as the minimum was raised in 1877 from 33 in. to 34 in. it may be fairly assumed that the average would be higher in 1879 than in 1874. It would thus appear that as regards age, height, and chest-measurement, there has been a marked improvement in the quality of the recruits in the last five years. But if the comparison be made with those raised in 1865—a date anterior to any of the changes in the organisation by which the average age of the soldiers has been so materially reduced—the improvement in the physique of the recruits will be found still more strongly marked. In that year the proportion under twenty years of age amounted to 549, under 5 ft. 6 in. in height to 400, and under 130 lb. in weight to 577 per 1000 inspected; so that in all these respects, but especially in height and weight—qualities which can be accurately measured,—there has been a very satisfactory improvement. The Inspector-General remarks that "we purchase this improved physique of the Army at the expense of rejecting annually a much higher percentage of the men who offer themselves as recruits." But we fail to see any disadvantage in this. If, as we have already shown, the service attracts so many young men that we are enabled to keep it even above the authorised establishment with this higher proportion of rejections, it is a fair inference that the improvement above noted is due to the circumstance that it is thereby possible to enforce a higher standard of physical fitness for service. The report shows, as regards the classes from which the recruits are drawn, that there has been an increase in the number of men raised from that of "mechanics employed in occupations favourable to physical development—as smiths, masons, carpenters, &c.," and of "shopmen and clerks," who are stated to make very excellent non-commissioned officers; while there has been a decrease in the class of "labourers, husbandmen, and servants," and of "manufacturing artisans." As might have been anticipated, there has been a decided increase in the educational acquirements of the recruits—a result doubtless due to the marked progress in the general population under the Education Acts. The preceding results show that the complaints made by general officers of the youth of the Army and the want of physique are due, not to a falling off in the quality of the recruits, or, as alleged by some, to a general deterioration of our population, but to the removal of the old soldiers by the expiration of the term of service of those enlisted under previous Acts, and by the transfer to the reserve of those enlisted under the Act of 1872, after completing their six years of service with the colours.

From a return appended to the report we find that the mortality of the army at home and abroad during the year 1880 amounted to 17·59 per 1000 of mean strength. This is considerably higher than the mortality in 1878, the year included in the last published volume of the Army Medical Department, but approximates closely to the average of the ten preceding years. The proportion discharged by invaliding during the year was 21·88 per 1000, being 6 per 1000 lower than in 1878, but almost identical with the average ofthe ten years. There is every reason to anticipate a reduction in the invaliding in each succeeding year by the operation of the transfer of men to the Reserve at a much earlier period than that at which they were formerly released from the service.

◆

ALL the preliminary steps for the Census enumeration of 1881 ought now to be complete. Before this issue comes under the eyes of our readers the Householders' Schedules should have been duly delivered by the large army of enumerators, and be already in the hands of the heads of families. The few simple particulars required by the Census Act, which are precisely the same as those asked for in 1871, should be entered in the schedule for each individual sleeping or abiding within any abode during to-morrow (Sunday) night, in order that the schedules may be ready for delivery to the enumerator, who will call for the same in the course of Monday next. Before nightfall on Monday next the first important stage of the Census of 1881 will have been completed, and, national curiosity having been excited, the results of the numbering will be awaited with a certain amount of expectancy, if not impatience. The Registrar-General's instructions to the various officers concerned in taking the Census contain what is called a Census Calendar, from which we may form some idea of the machinery by which the individual householder's schedule will be made to yield the final results of the national enumeration. On Monday night next about six millions of individual householders' schedules will have been collected by about 35,000 enumerators throughout England and Wales. These enumerators are allowed a week for copying the contents of these individual schedules into enumeration books, and on or before the 11th of April these books, together with the original schedules, should be delivered to the registrars by whom the enumerators have been appointed, and who are responsible for the efficient enumeration of their subdistrict. Before the expiration of another fortnight, that is, on or before April 25th, registrars should have forwarded all the original schedules to the Census Office in Craig's-court, and the enumeration books, together with all other census documents, to their superintendent registrar. These officers are in their turn allowed a week for revising the enumeration books, and the summaries of the same, and are instructed that on or before the 30th of the month part of the revised enumeration books should be forwarded to the Census Office, and that the remainder is to follow in rapid succession. Thus if the Registrar-General's programme be strictly carried out the staff of clerks in the central office at Craig's-court will be busily engaged before the end of the present month finally revising the enumeration books, which will previously have passed through the hands of the enumerator, the registrar, and the superintendent registrar. Between the end of April and the middle of June will be prepared the Preliminary Census Report for presentation to Parliament. This report, in addition to the now population of England and Wales, and of its counties, and registration divisions and subdivisions, will probably show the number of persons (distinguishing the sexes) enumerated in each borough, local government district, and other urban sanitary district. In this preliminary report no attempt will be made to show the ages, civil condition, or occupation of the people. This and other information will find place in the final Census Report, and will be published from time to time during the two years which will elapse before the information to be derived from the householders' schedules, now in the hands of heads of families, will be completed, and be fully available for the use of the public.

Annotations.

"Ne quid nimis."

THE ILLNESS OF LORD BEACONSFIELD.

A SINCERE feeling of concern for the state of the Earl of Beaconsfield pervades the community without reference to rank or politics. This has been rendered conspicuously apparent by the inquiries made at Curzon-street, personally by the Prime Minister, and the leading members of the Liberal party, as well as those of his lordship's own following. It is, of course, with the medical aspects of the illness that we are more particularly interested. A curious announcement has appeared in the daily papers to the effect that Lord Beaconsfield has not been treated "homœopathically," but "according to the regular practice of allopathy." The medical profession does not recognise any "pathy"! There is a system of medicine—based on the knowledge of Nature's order in health, the manifestations of disease, and the ascertained effects of remedies and methods of treatment—which is accepted and practised by the common consent of the profession. Without at the moment entering upon the ethical question raised by the consultations in this case, it may be stated that hypotheses of cure by similars and cure by contraries have no place in scientific medicine; and we hold that no member of the medical profession is justified in committing himself to a school which affects to adopt either of these principles as the basis of a systematic treatment of disease. Still less can any member of the profession be at liberty to adopt either of the two systems indifferently or at the pleasure or whim of his patients. What would be thought of a lawyer who adopted a private interpretation of the statute book, or of one who offered his clients a choice of two methods? Nature is not less inexorable in her demand for the intelligent submission of her disciples to the known laws of health and disease than are the Courts of Judicature. No law of Nature is of private interpretation. It must therefore be evident that the notification that Lord Beaconsfield has not been treated "homœopathically," but "according to the regular practice of allopathy," has no professional significance. The reports of Lord Beaconsfield's illness which have reached us seem to indicate a state not very difficult to recognise. He is probably suffering from an affection which the late Sir Henry Holland was among the first to describe—namely, that form of inflammatory congestion of the bronchial apparatus which occurs in connexion with the gouty diathesis, more particularly when the constitutional malady is not, as it were, focused and restrained by localisation in the usual form. The noble Earl suffers from a lack of nerve power—as distinguished from cerebral energy—which is by no means uncommon in men of Lord Beaconsfield's type. The intensity of his lordship's vital force has for many years been remarkable, but it has been mainly due to *mental* energy, called forth in response to mental stimuli. With an organism so energetic and thus vitalised, there must needs be a perpetual liability to the suppression or metastasis of diseases which require a somewhat high grade of local disturbance to reach their normal type; meanwhile there is necessarily much irritability and weakness. The difficulties attending the management of such a case are obviously great, and its vicissitudes many and various. We can only express an earnest hope that these difficulties may be surmounted, and that the Earl of Beaconsfield may be spared to resume the prominent position in the Legislature from which he has been so inopportunely displaced.

A CRITIC'S MORALITY (?)

A QUARTERLY publication called *The Modern Review*, in its issue dated April 1st, contains nine articles, all of which are duly authenticated and signed, save one. The unique exception is entitled "The Medical Profession and its Morality." It is not quite clear why the writer of this lucubration should have kept back his name, nor does the maudlin and impertinent apology of the editor furnish any explanation why his "esteemed contributor" should "prefer to withhold his signature." A writer so dead to even the forms of truth, honesty, and decency can surely have no occasion to respect either his person or his name. It would seem rather to have been mean, craven cowardice that prompted the discretion. Otherwise it is almost incredible that anyone should have deliberately published anonymously such odious and wanton charges in a magazine having all its other articles signed and acknowledged. Here are some "elegant extracts" from this reviewer's pages :—"Apparently there are cases where cure is not an object! Plumbers are popularly believed never to mend one hole in the leads of a house without making another. The gentlemen whom we call in to tinker our internal pipes and gutters, it is to be feared sometimes adopt similar tactics." "As a *profession* [the italics are *not* ours] the guilt and shame of the atrocious Contagious Diseases Acts lie at the door of the medical men of England, and it is their gross materialism, their utter disregard for human souls when lodged in the bodies of the despised and wretched which has made such legislation possible." "The profession has proved doubly treacherous to women." It is neither necessary nor dignified to heed such false, foolish, and hysterical charges. The gratitude, respect, and esteem of an intelligent and virtuous community afford a complete and final answer. The professional good conscience can therefore well afford to disregard the skulking diatribes of a "Modern Reviewer."

NON-COMBATANTS.

THE official despatches from the Transvaal, published in the *Gazette* of the 22nd ult., bear out fully the opinion we have repeatedly expressed of the injustice of classing medical officers with non-combatants in the distribution of rewards and honours. The late Colonel Anstruther, in his report of the action at Bronker's Spruit on the 20th December, says :—"It was exceedingly fortunate that Providence spared our only medical officer and his assistant-surgeon. Ward's work can hardly be described. It was endless for forty-eight hours; until assistance arrived he had not a moment to himself." We may add that Surgeon Ward's name appears in the list of the wounded. Sir George Colley also in his account of the fight at Ingogo, reported: "Surgeon M'Gann well maintained the distinguished reputation of the medical department for self-sacrificing exposure in attendance on the wounded until the arrival of the ambulances with Surgeons Ring and Landon; he was the only medical officer with the force, and laboured indefatigably with the wounded." *The Times*' correspondent, in his account of the action, says: "Where all were calmly courageous it seems invidious to make mention of any; but Dr. M'Gann, Army Medical Department, behaved splendidly. He never spared himself for an instant; whenever the cry was heard, 'Pass the word for the doctor,' he quickly made his way to the wounded men, making himself, for the nonce, the most prominent target for the Boer marksmen." Such are the men, such their deeds, and such the dangers to which they are exposed in the discharge of their important duties, whom the authorities at the Horse Guards persist in classing with non-combatants when rewards and honours are being conferred. We do not find that they so regard them when their services are required. Surely it is time that the War Minister should interfere to put an end to so glaring an injustice. We sincerely trust that Mr. Childers will take up the question, as we have little doubt if he does so his sense of what is right will lead him to make such arrangements as will put an end to so unjustifiable an anomaly.

THE PATHOLOGY OF CARBUNCLE.

ALL authorities have been for a long time agreed that the central fact in the pathology of carbuncle is death of a certain portion of tissue, but there has been, and is now, considerable difference of opinion as to whether it is death of a portion of the true skin, or of the cellular tissue, or of both, or of a gland. The clinical features of the affection, although well marked, are hardly sufficient to settle the point, and thus equally good surgeons have held these diverse views. Dr. J. Collins Warren, of the Harvard University, has devoted considerable attention to this subject, and has come to the conclusion that the pathology of carbuncle is closely connected with certain structures in the skin hitherto undescribed, which he has named the columnæ adiposæ. It is stated that in thick skin bearing only fine downy "lanugo" hairs, there are nearly vertical clefts and slender columnar spaces reaching from the bottom of the hair-follicles through the deeper parts of the corium into the subjacent panniculus adiposus. These spaces are filled with fat, bloodvessels, lymphatics, and usually also a coiled-up sweat-gland; and it is to these that the term columnæ adiposæ is applied. At about their middle, lateral horizontal branches are given off, which form a series of intercommunicating channels in the corium, which can be injected from the subcutaneous fatty layer. Close by the deeper end of each column a broad bundle of fibrous tissue passes from the corium through the fatty layer to the deeper fascia. The neighbouring bundles interlace in various directions; they connect the skin and deep fascia more or less firmly together. These columns are only found in connexion with hair-follicles, and in thick skin with downy hairs; in other conditions the follicles reach quite through the corium. The vessels, which all reach the cutis vera by piercing its deeper surface, are only found taking this course along these fat columns, and giving off lateral branches along its offshoots. In sections made through the margin of a carbuncle, Dr. Warren finds that the first change is an infiltration of the subcutaneous fatty tissue with wandering cells which creep up the columnæ adiposæ and along their lateral branches and secondary offshoots, and so ultimately infiltrate the whole thickness of the true skin, except a thin superficial layer, which being free from these channels does not afford the spaces along which the cells can wander. This is accompanied with swelling and elongation of the columns, and the destruction of their normal contents, and they now are visible to the naked eye as small prominent pustules, often with a fine downy hair attached.

But another origin has also been found for the small superficial pustules. The papillæ become infiltrated and œdematous, much swollen, and often balloon-shaped, with the narrowed end deep; they then project above the surface, their contents break down into pus, and quickly escape. Adjacent papillæ may unite, and so form rather larger pustules; and, on the other hand, the process may stop short of suppuration, and the inflamed tissue retrograde. Meanwhile the subcutaneous infiltration continues, extends, and intensifies, but cuts off the blood-supply without melting down the deep bundles of fibres passing through it, which therefore form the tough adherent sloughs at the bottom of carbuncles. The true nature of carbuncle may therefore be said to be purulent infiltration of the subcutaneous tissue, with secondary injection of certain normal cavities in the true skin, and inflammatory products, which compress the nutrient vessels and lead to suppuration and sloughing. The common situation of carbuncle and its altered character when attacking skin where the corium is very thin or the hairs long and stiff, show that the explanation of its peculiarities must be looked for in some anatomical arrangement. The marked relief obtained by incisions is fully explained by this pathology. Dr. Warren states that not only purulent infiltrations but new growths, such as sarcoma and nævus, spread up to the surface along these columnæ adiposæ, and that this condition may then be readily recognised by the naked eye.

THE CHAIR OF PATHOLOGY IN EDINBURGH.

Our Edinburgh correspondent writes:—For the Chair of Pathology in the University, which will be filled up in the course of April, the following candidates have come forward: Dr. Byrom Bramwell, late of Newcastle-on-Tyne, now Lecturer on Medicine in the Extra-Academical School here; Dr. Greenfield of St. Thomas's Hospital, Superintendent of the Brown Institute; Dr. Hamilton, at present Pathologist to the Royal Infirmary, who, as assistant to the late Professor Sanders, conducted the course of lectures during his illness, and who has conducted the class of Practical Pathology for the last few years; Dr. Rabagliati of Bradford; and Dr. Roy, formerly assistant in the University of Strasburg, &c. It is rumoured that the curators will select either Dr. Hamilton or Dr. Greenfield.

FIRE AND PANIC IN THE THEATRE.

The tragedy at Nice will recall public attention to the state of our own theatres for the moment, and then the ever-present danger will be forgotten again until some hideous holocaust, perhaps involving the loss of hundreds of lives, once more revives a problem which, being unable to solve, the authorities and the public seem equally anxious to shelve. The facts are simply these: there are not half a dozen theatres in the metropolis, and probably not more than a score in the country, from which escape in an emergency would be practicably possible. This statement is so opposed to the interests of lessees, so humiliating to those who have planned and superintended these constructions, and so discreditable to the licensing authorities, that it is quite sure to be contradicted or ridiculed. Nevertheless, it is simply and grimly accurate. There was something grotesque in the recent order to provide extra doors for use "in case of fire." Are those who legislate for the security of life under conditions of panic so ignorant of the nature of panic as not to know that its first effect is to obliterate all traces of transitory and recent impressions and to place the whole being at the mercy of impulse and habit? If a particular doorway is to be used as a means of exit in an emergency, it must be employed as a way of entry and exit on ordinary occasions. If it did not generally happen that the "extra" doors of theatres are locked when they ought to be open, it would still be absurd to rely on such exceptional means of escape. It would be altogether impossible that a fairly full audience could be got out of a London theatre without fearful casualties if panic prevailed. Some of the most frequented and fashionable theatres are the worst. Nevertheless, this state of things is tolerated, and a Select Committee has gone through the farce of examining a multitude of interested witnesses and framing a report full of the feeblest and most inadequate suggestions, while a Lord Chamberlain has issued a few puerile directions for the adoption of measures of no possible effect. It is useless to dwell on the matter. The community of playgoers elect to take their chance, and their entertainers and official protectors are content that they should do so. Who, then, has any right to complain?

PSEUDO-MEDICAL ADVERTISEMENTS.

The reference made in the course of the trial so generally described as the suit Lawson *v.* Labouchere, to the protest entered by The Lancet against pseudo-medical advertisements of an indecent class appearing in lay newspapers, recalls the following sentences which we penned in 1864–5: "The sin of this quackery shall not lie at the door of the medical portion of the press. Let us hope that the press generally will come to a similar resolution, and show the strength of it by foregoing the profits which accrue from advertisements, . . . which, indeed, are fast rendering ordinary papers unfit for introduction into families." Again: "No doubt to many a struggling journal the sums so received constitute an inducement which pleads very urgently for the continuance of a practice which is so largely lucrative. But if the attention of the general public be sufficiently awakened to the vile nature of this traffic this inducement will cease, for the loss of circulation and the loss of character incurred by journals which shall continue to defile their columns by the announcements will more than counterbalance the direct profits of the paid insertions. There is no reason that we can see why it should be considered much less disgraceful to print this sort of obscenity, than it would be to introduce it into written correspondence or ordinary conversation. The journalists who permit their columns to be so abused are undoubtedly the accomplices of those whom they freely denounce in their leading articles."

CINCHONA PLANTATION IN BOLIVIA.

The cultivation of the cinchona in the East Indies, which was originally undertaken on account of the prospect that the supply from South America would ultimately come to an end, is having a beneficial reaction, and in Bolivia, at least, energetic attempts are being made to keep up the stock which was in danger of a not distant extermination. The effort originated with private individuals in 1878; already (according to the report of the Dutch Consul) there are on the banks of the Mapiri at La Paz four or five hundred thousand young trees of two years' growth. In other places new plantations are springing up, chiefly on the mountain slopes, which are cultivated for three-fourths of their height, while the cinchona tree is found growing on the summit or in valleys and ravines. The tree was once abundant over the slopes, but has long since disappeared from them, under the wasteful system of destroying the trees. Even now the trunks of trees may be found rotting on the ground, the bark removed from the upper surface only.

The task of culture is an easy one in the original haunts of the cinchona. It only requires a few days in the year to clear the ground necessary for a cinchona plantation, to transplant the young trees from the nurseries, and to keep the ground free from weeds during the first and second years, and afterwards the trees may be left to themselves. But in the uncultivated tracts of land more capital and labour are required, although the expense of purchase is not great, since a tract of land fifty-nine miles long was sold for £100. The clearing away of the dense forest is the most troublesome part of the work. Banana trees are planted between the cinchona seedlings to give them shade for the first year or two, when the chief danger is from drought and ants.

It is estimated that these plantations may possibly be a source of danger to the cinchona cultivators of India if they are managed with energy, and that whether sufficient zeal will be forthcoming will depend on the cinchona bark maintaining its high price. If its price falls considerably, the cultivation of cocoa will be more profitable, and the supply of labour scarcely suffices at present for energetic attention to the two industries.

FLOGGING IN THE ARMY.

IT is with especial satisfaction we hail the abolition of flogging in the army. This is one of the reforms which the late Mr. Wakley set on foot, and in regard to which he was deeply in earnest. THE LANCET, as an organ of professional opinion, has always taken a prominent part in the movement. The "Hounslow inquest" will be fresh in the recollection of many of our readers; and it will not be forgotten that the inquiry, which elicited the most startling and significant facts, was adjourned ten times. The lash was then shown to be a weapon capable of inflicting formidable and even fatal injuries on the deep structures, while apparently doing little harm to the superficial. It was found to be a murderous and wholly misleading instrument of torture. The moral effect a punishment of this degrading character must needs produce on the mind of its subject is obvious to everyone who, not being the victim of red tape, has taken the trouble to think about the matter seriously and impartially. At last, then, flogging is at an end. It would have been wise and more gracious if the opposition offered to this necessary reform in high quarters had been withdrawn before public opinion compelled a submission which common sense had long dictated.

PASTEUR'S NEW DISEASE.

IN THE LANCET for Feb. 5th, p. 220, we called attention to the remarkable effects which M. Pasteur had obtained by inoculating rabbits and guinea-pigs with the saliva of a child which had died from hydrophobia. The animals, it will be remembered, died thirty-six hours after inoculation, and in their blood was found a bacterial organism, which was quite peculiar, which could be cultivated, and then produced, when inoculated into other animals, symptoms identical with those observed in the others. M. Pasteur did not assert that this was the special microbic organism of rabies, but he considered that his experiments and the microscopical characters of the organism warranted the assertion that the disease was not septicæmia, but a malady altogether new to experimental pathology. In order to ascertain whether a similar affection can be produced by the inoculation of the saliva of persons who have died from other common diseases, M. Pasteur has made some inoculations with such saliva, but without any results. But since the case of hydrophobia was in a child, M. Pasteur applied to M. Parrot for some saliva from children dying from diseases which are regarded as non-specific, and received some from the bodies of three children who had died the preceding day from broncho-pneumonia. In rabbits inoculated with this saliva there was found precisely the same organism as had been discovered in those which had been inoculated with the saliva from the case of hydrophobia. He thinks it certain, therefore, that this organism may often be found, and that it is one of those which have their habitat in the commencement of the alimentary tract. Hence, as he points out, it is not in any way connected with rabies, but it is a surprising fact there should exist in the saliva, at least of children, a special organism which is capable of causing so rapidly the death of rabbits and dogs, even when inoculated in very small doses. It is a fact of very great importance in the etiology of diseases which may be ascribed to microscopic organisms.

THE GENERAL MEDICAL COUNCIL.

WE understand that the General Medical Council is summoned to meet on April 26th, and the Executive Committee on the 12th. It is not easy for outsiders to divine what can be the justification of another meeting of the Council in less than two months after the last, when the Council came from the four winds, and at a great cost, for one day, to reinstate a few hundred deregistered dentists under the Dentists Act, very much at the bidding of counsel. Another meeting at a very inconvenient season does not necessarily therefore mean anything urgent, or any business in which the profession or the public can have much interest. *Nous verrons.*

HOSPITAL SATURDAY.

A GREAT effort is being made in Liverpool to make the Saturday collections, representing the interest of workmen in hospitals, more satisfactory than hitherto. It is thought if employers of labour would take the trouble to have the object fairly and systematically placed before their *employés* the object would be gained. Liverpool, in this matter, does better than London. But Liverpool is far behind Birmingham. In eight years the working men of Liverpool, with a population of 150,000 more than that of Birmingham, have contributed £16,738 14*s.* 10*d.*, against £29,815 9*s.* 1*d.* by the smaller population. The secretary of the Hospital Saturday movement in Birmingham modestly attributes the difference to more system rather than to more liberality. He says: "We find the largest contributions are received from those establishments where a systematic collection is made—that is to say, where a sum is set aside weekly. The men do not miss a penny a week, but 4*s.* 4*d.* out of one week's wages would be a very heavy tax on them." We cannot but hope that the working-classes, with their growing power of organisation, will, with or without assistance from their employers, see that this object is one deserving of systematic help, and one in which their credit is concerned. To set aside a penny a week for a worthy contribution to great national charities, existing chiefly for their benefit, is surely only a reasonable sacrifice.

ROYAL COMMISSION ON THE MEDICAL ACTS.

THE *Daily News* of the 23rd ult. had an article approving the determination of the Government to refer the investigation of the Medical Acts to a Royal Commission, and pointing out that everything depends on the composition of the Commission. Our contemporary says: "The earnestness of the Government will be judged by the composition of the Royal Commission. Successive Governments have been misled much in this matter through consulting only the General Medical Council, which is the very body and represents the very bodies under criticism. If the General Medical Council is to advise the nominations, we need not say that the Royal Commission will be a form, not to say a farce, and had better not be appointed." Our contemporary goes on to express confidence in the Government and its belief that the Commission will be one that will command the respect both of the public and of the medical profession. One thing is certain, that the public will not in this matter have faith in a Commission which does not commend itself to the medical profession.

THE RUSSIAN RED CROSS SOCIETY.

In an engagement with the Tekes on the 21st July (2nd August) last, Dr. Stouditsky, one of the medical men attached to the detachment from the Red Cross Society with the Transcaspian Army, was killed. He left a widow entirely unprovided for. The circumstances were brought to the attention of the late Emperor in a report presented to him on the 15th (27th) February last, and, in recognition of the services which had been rendered by her husband during the Transcaspian campaign, he was pleased to accord to Madame Stouditsky a life pension of 600 roubles.

A very large gathering of Guy's men from all parts of the country took place at the rooms of the Medical Society of London, Chandos-street, W., on Friday, March 25th, on the occasion of the presentation of a testimonial to Dr. Habershon and Mr. Cooper Forster. Mr. Lund of Manchester presided, and in the names of the subscribers, who numbered more than three hundred, presented to Dr. Habershon and Mr. Cooper Forster respectively a handsome silver épergne and an album, containing an address, followed by the names of the subscribers. Dr. Habershon and Mr. Cooper Forster were most cordially received, and the meeting passed off in the most satisfactory manner. A large number of those present then adjourned to the Langham Hotel, where Dr. Habershon and Mr. Cooper Forster were entertained at dinner.

Professor Helmholtz is announced to deliver the Faraday Lecture at the Royal Institution, Albemarle-street, on the occasion of the triennial festival of the Chemical Society to be held on the 5th inst. The subject will be "On the Modern Development of Faraday's Conceptions of Electricity."

The Managers of the Edinburgh Royal Infirmary have issued a report confirming the system of tutorial instruction as conducted in the medical and surgical wards. They practically continue to ignore the requirements of students in gynæcology, since they altogether abstain from making mention of that subject in their report.

On March 13th, 1881, Mr. Warrington Haward employed the rectal lever in a case of amputation at the hip joint. The following week Mr. Richard Davy used the lever as a valuable diagnostic agent, prior to deligation of the left external iliac artery.

The death is announced of Dr. Harkin, of Vanleekhill, member of the Ontario Legislature.

Guy's Hospital.—At a meeting of the Medical and Surgical Staff of Guy's Hospital, held March 14th, 1881, it was resolved :—"That the best thanks of the Medical and Surgical Staff of Guy's Hospital be offered to the members of the Norwich Medico-Chirurgical Society, for the vote of sympathy sent to them by the Society in January last. That the Society be informed that the staff of Guy's Hospital have never for a moment relaxed their efforts to accomplish the object they had first in view—viz., to place the medical staff in their right position as regards the management of the Hospital; and they are happy to state that all questions affecting the medical care and nursing of the patients are referred to a committee, on which the staff are now represented."

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Chesterfield (*Rural*).—Dr. Angus Mackintosh's report for this district for 1880 is, as usual, noteworthy for the conscientious care with which it deals with the several duties which the medical officer of health has to perform in relation to the particular district. The death-rate was equal to 20·2 per 1000 inhabitants, the birth-rate to 48·0. Dr. Mackintosh directs particular attention to the effects upon the health and comfort of colliers on their return home direct from the pit in their begrimed clothes, contaminating the atmosphere of the dwelling with coal-dust, blackening and soiling whatever they touch, while as a rule their contracted cottages are destitute of that facility for cleansing persons and things which it is desirable they should have. He makes the following admirable suggestions to colliery owners:—"1. That large and commodious baths, with proper accommodation for changing clothes, should be provided in connexion with each colliery in the district, so that every collier on reappearing on the surface, and after divesting himself of his working habiliments, shall be thoroughly washed in warm water, not less than 120° Fahrenheit, and afterwards in cold. 2. That the collier shall always wear a clean suit of clothes on going to and coming from his work, and never take the working or pit-clothes home to his house. 3. That compliance with such rules should be made imperative by the employer on all men commencing work, and that all expense should be defrayed in the first instance by him."

Lytham (*Urban*), *Lancashire.*—Mr. William E. Pountney reports the completion of certain improvements in the drainage of this pleasant health-resort. The death-rate in 1880 was as low as 16·6 per 1000 inhabitants. Lytham, however, it would appear, still wants a sanatorium, and Mr. Pountney again urges the desirability of the sanitary authority providing one.

Handsworth (*Urban*), *Yorkshire.*—In an estimated population of 22,880, Dr. J. B. Welch reports for 1880 a birth-rate of 31·5 per 1000 inhabitants, and a death-rate of 12·5. Referring to infantile mortality, although he ascribes much of it to mismanagement, neglect, and improper feeding, he attributes also much to the influence of heat upon filthy surroundings, particularly the putrefaction of organic matters. Improvements seem in progress in the district in respect to the dealing with excremental matters, and we note that the sanitary authority has itself undertaken the removal of night-soil.

Thingoe (*Rural*), *Suffolk.*—Mr. Charles Scott-Kilner reports for this district in 1880 a birth-rate of 26·4 per 1000 inhabitants, and a death-rate of 15·2. He gives a curious instance of a case of diphtheria in a schoolboy occurring soon after an outbreak of sickness among fowls, which, if not diphtheria, closely resembled that disease. Overcrowding of cottages appears to have occupied the chief attention of the sanitary authority during the year.

Bakewell (*Rural*), *Derbyshire.* — Dr. Philip S. Fentem reports for the northern portion of this district in 1880 a birth-rate of 26·96 per 1000 inhabitants, and a death-rate of 16·01. Great care and labour were given by the sanitary authority to the abatement and prevention of nuisances throughout the year, and their requirements were carried out without the intervention of the magistrates.

Hartismere (*Rural*), *Suffolk.*—Dr. Edgar G. Barnes reports a birth-rate of 31·2 per 1000 inhabitants, and a death-rate of 16·8. The sanitary state of the entire district has improved. This improvement, Dr. Barnes says, "is shown not only in the smaller number of permanent nuisances requiring removal, but also by the greater care shown in preventing their recurrence by the inhabitants of the district." The report contains several instructive instances of the spread of infectious diseases from the carelessness of parents in regard to them. One is novel. Dr. Barnes found on visiting a cottage where scarlet fever existed a travelling draper there who had clearly been fitting convalescents from the disease with articles from his stock. He proceeded at once from this house to another house, uninfected, for the purpose of exhibiting this stock which had thus been exposed to infection.

Sunderland (*Port Sanitary Authority*).—Judging from his reports, Dr. Yeld must be regarded as a typical port medical officer of health. His report for 1880 is now before us, and, as previous reports, shows in the most effective way the sort of work which the port medical officer of health is called upon to do. The amount of shipping inspection got through in Sunderland is very large, and the influence of this inspection upon the sanitary condition of vessels since it was first instituted appears to be very gratifying. In 1876 not less than 60 per cent. of the vessels inspected were found in an insanitary condition; from this state there has been a steady diminution from year to year in the number, and in 1880 only 15 per cent. of the vessels inspected were found in an unhealthy state.

Liverpool (*Port Sanitary Authority*).—Liverpool appears to have been late in following the example of Sunderland, London, &c., in instituting a careful inspection of vessels. At least so we gather from a report of Dr. Stopford Taylor for 1880. It appears that the inspector appointed to examine and report upon the sanitary condition of vessels in the port only commenced his duties on the 6th September, and the report deals with data from that time to the 31st December. Dr. Taylor's statement in effect is that no difficulty has been experienced in carrying out the work of inspection, and that owners and masters have readily complied with the medical officer of health's requirements.

Wakefield (*Rural*).—Mr. Francis Henry Wood reports for this district in 1880 a birth-rate of 36·0 per 1000 inhabitants, and a death-rate of 18·0, the population being estimated at 34,583. Although no great results have to be recorded, a good deal of detailed sanitary work appears to have been done in the district.

SMALL-POX HOSPITALS: A NEW LIGHT.

Mr. Wynter Blyth, in his last published monthly report to the Marylebone Vestry—that for February—suggests a plan of hospital construction, prepared, he states, "with the very kind assistance and encouragement of Dr. Richardson," which shows, what we were not prepared to anticipate, that according to him it is necessary to reconsider some of the fundamental rules which have governed us for some time in designing infectious disease hospitals. It has come to be a rule among professed hygienists and medical men that the wards of a hospital erected for the reception of contagious or infectious disease should have per bed at least 2000 ft. of cubic space, and 144 ft. of superficial space if the requirements of the patient as to due ventilation are to be secured. But Mr. Wynter Blyth's suggestions to his authority imply that only 800 feet of cubic space and 53½ feet of superficial space are alone necessary even in the case of small-pox. There is nothing said in the report as to how this astonishing divergence of view from commonly accepted opinion has been brought about. On the contrary, this divergence is not deemed worthy even of comment, and the suggestion is made as if it involved nothing novel. Nay, indeed, it is stated that the measurements suggested "give sufficient space per head." Assuming that Mr. Blyth is right, here at least is a solution of the present difficulty in which the Metropolitan Asylums Board are placed. For, as in the small-pox hospitals of that Board an allowance per bed of 2000 feet cubic space and 144 feet superficial space is given, it is obvious that they may, according to Mr. Blyth's notions, place in their hospitals five patients for every two patients they now place there, and thus at once more than double their present accommodation for small-pox cases. But is Mr. Blyth accurate in his opinion? The question can scarcely be treated seriously. It is proper to mention that, in view of the Marylebone Vestry being called upon to provide hospital accommodation for cases of small-pox, Mr. Blyth states that he has already reported to the Sanitary Committee of the parish in the sense of his suggestion, and that his monthly report gives an abstract of his views only.

At a recent meeting of the guardians of the City of London the following resolutions were adopted unanimously:—(1) "That this Board is of opinion that no more payments should be made by the board of managers of the Metropolitan Asylums District towards the liquidation of the enormous amount (said to be upwards of £40,000) for law costs in the legal proceedings relating to the Small-pox Hospital at Hampstead, until the total amount be ascertained and communicated to the various parishes and unions comprised in the said Metropolitan Asylums District, with the fullest information and explanations that can be furnished of the whole matter, quoting by what authority and by whose advice the steps were taken for the defence of the action against the managers." (2) "That this Board protests against the contemplated action of the Metropolitan Asylums District managers as to taking further legal proceedings with regard to Hampstead Hospital."

Now that private enterprise is about to be handicapped in the matter by Government it would appear, strange to say, as if we were about to have a shower of establishments for furnishing calf lymph for vaccination. Dr. Cook is doing excellent work at Manningtree, Dr. Warlomont's agency at 3, Hemming's-row is prospering, and now Dr. Renner has opened an establishment at 228, Marylebone-road, not only for the supply of lymph, but also for the vaccination of children on appointed days and at a specified time from calf lymph.

There has recently been a correspondence between the guardians of Lambeth and the managers of St. Thomas's Hospital respecting the mode of dealing with cases of small-pox which may incidentally occur among the out-patients of the hospital, and a satisfactory arrangement has been made by which such patients may be removed to a hospital of the Asylums Board with the least practicable delay, diminishing the risk of contagion to other out-patients to the utmost, and obviating the danger to the public generally arising from the exposure of patients in the streets.

At a meeting of the Fulham Guardians on the 24th ult., the Clerk stated that there were forty-eight patients from the district in the small-pox hospital in the district, and that there were only three vacant beds there. A member took exception to the action of the committee of inhabitants to close the hospital, observing that if the hospital were closed there would be no accommodation for cases occurring in the parish. But another member explained that the committee only desired to exclude cases of small-pox from other districts of the metropolis.

In consequence of the approaching demolition of the Surrey Chapel in the Blackfriars-road, where the principal station of the National Vaccine Establishment has been held since the beginning of the century, arrangements have, we understand, been made by the Local Government Board for the continuance of the work of the Station at the Victoria Hall, Lancaster-street, Friar-street, Blackfriars-road, where Dr. Robert Cory will vaccinate as heretofore on Tuesday and Thursday of each week at one o'clock in the afternoon.

We are glad to notice proceedings taken by the local authorities against builders, both in Hornsey and Hammersmith, for improper work in new buildings affecting their stability and also sanitary condition.

Poplar is still in doubt whether it should use or not its hospital at West Ham for the reception of small-pox cases. The question has again been postponed.

Notice has been given to the Metropolitan Asylums Board of proceedings to be instituted for an injunction to be obtained against the Homerton Small-pox Hospital.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

Although showing a slight increase last week, mortality in the large English towns continues very low for the time of year. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 5199 births and 3163 deaths were registered last week. The births exceeded by 13, while the deaths were 94 below, the average weekly numbers during 1880. The deaths, however, showed an increase of 162 upon the low number returned in the previous week, and were equal to an annual rate of 21·7 per 1000, against 23·0 and 20·6 in the two preceding weeks. The lowest death-rates in the twenty towns last week were 17·2 in Salford, 17·5 in Norwich, 17·6 in Nottingham, and 18·0 in Birmingham. The rates in the other towns ranged upwards to 25·0 in Leeds, 25·6 in Portsmouth, 26·2 in Plymouth, and 28·1 in Liverpool. During the first twelve weeks of the current quarter the death-rate in the twenty towns averaged 24·0 per 1000, against 25·6, the average rate in the corresponding periods of the five years 1876–80.

The deaths referred to the principal zymotic diseases in the twenty towns, which had been 311 and 287 in the two preceding weeks, rose to 321 last week, and exceeded any recent weekly number. These 321 deaths included 78 from whooping-cough, 56 from scarlet fever, 55 from measles, 51 from small-pox, and 37 from fever, principally enteric. The annual death-rate from these principal zymotic diseases averaged 2·2 per 1000 in the twenty towns, and ranged from 0·5 and 0·6 in Brighton and Nottingham, to 3·4 both in Portsmouth and in Newcastle-upon-Tyne. Whooping-cough showed the largest proportional fatality in Newcastle-upon-Tyne, Leeds, Sheffield, and Portsmouth; and scarlet fever in Bradford and Sunderland. Of the 17 deaths from diphtheria in the twenty towns 7 occurred in London, 3 in Portsmouth, and 2 in Bristol. The death-rate from fever (principally enteric) was highest in Portsmouth and Oldham. Small-pox caused 52 more deaths in London and its outer ring of suburban districts, one in Birmingham, one in Newcastle-upon-Tyne, and not one in any of the seventeen other large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had steadily increased in the twenty-one preceding weeks from 77 to 853, declined last week to 820. The new cases of small-pox admitted to these hospitals during last week were 147, against 186 and 265 in the two previous weeks.

The deaths referred to diseases of the respiratory organs in London were 348 last week, against 384 and 345 in the two previous weeks, and were 122 below the corrected average number in the corresponding week of the last ten years; 217 resulted from bronchitis and 77 from pneumonia. The annual death-rate from lung diseases, exclusive of phthisis, was equal to 4·9 per 1000 in London last week; while the rate from the same diseases in Liverpool was 7·7, and in Salford 4·6.

The causes of 65, or 2·1 per cent., of the deaths in the twenty towns last week were not certified, either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths did not exceed 1·2 per cent. in London, while it averaged 2·9 per cent. in the nineteen provincial towns. All causes of death were duly certified in Portsmouth, Norwich, Plymouth, Leicester, and Nottingham; while the largest proportions of uncertified deaths occurred in Wolverhampton, Oldham, and Leeds.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate averaged 23·5 per 1000, against 23·4 and 23·1 in the two preceding weeks; this rate was 1·8 above the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 15·6 and 20·3 in Perth and Greenock, to 26·2 and 27·8 in Aberdeen and Leith. The deaths referred to the principal zymotic diseases in the eight towns, which were 82 and 97 in the two previous weeks, declined to 75 last week; they included 27 from whooping-cough, 14 from diphtheria, 12 from diarrhœa, 10 from scarlet fever, 6 from "fever," 6 from measles, and not one from small-pox. The annual death-rate from these zymotic diseases was equal to 3·0 per 1000, and was 0·8 above the average rate from the same diseases in the twenty English towns. The zymotic rate in the eight Scotch towns last week ranged from 0·0 and 1·1 in Perth and Paisley, to 3·4 and 6·1 in Glasgow and Leith. The fatal cases of whooping-cough in the eight towns, which had been 8 in each of the two preceding weeks, declined to 27 last week. Of the 14 deaths referred to diphtheria, 9 occurred in Glasgow and 2 in Edinburgh. The 12 deaths attributed to diarrhœa showed a decline from recent weekly numbers. The 10 deaths from scarlet fever included 5 in Edinburgh and 3 in Leith; and of the 6 fatal cases of measles, 3 occurred in Glasgow and 3 in Aberdeen. The deaths referred to "fever" showed a considerable decline from the numbers in recent weeks; and the death-rate from this cause in the eight towns almost corresponded with that which prevailed in the twenty English towns during the week. The deaths referred to acute diseases of the lungs, which had been 179, 168, and 164 in the three preceding weeks, further declined to 138 last week, and were equal to an annual rate of 5·5 per 1000, against 4·2 from the same diseases in London.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had slowly but steadily declined during the eight preceding weeks, showed a marked increase again last week. The annual death-rate last week was equal to 34·9, against 33·8 and 30·4 in the two previous weeks. During the past twelve weeks of the current quarter the death-rate in the city has averaged 38·4 per 1000, against 23·6 in London and 22.5 in Edinburgh. The 223 deaths in Dublin last week showed an increase of 29 upon the number in the previous week, and included 19, or nearly 9 per cent., which were referred to the principal zymotic diseases, against 23 and 11 in the two previous weeks. These 19 deaths from zymotic diseases included 12 from fever (typhus, enteric or typhoid, and simple continued), 2 from whooping-cough, 2 from scarlet fever, 2 from diarrhœa, one from diphtheria, and not one from small-pox or measles. The annual death-rate from these zymotic diseases was equal to 3·0 per 1000 in Dublin last week, against 2·7 in London and 3·3 in Edinburgh. The deaths referred to fever in Dublin, which had been 10 and 4 in the two previous weeks, rose to 12 last week; the annual death-rate from this cause was more than seven times as high in Dublin as the average death-rate from fever in the twenty large English towns. The recorded deaths from scarlet fever and whooping-cough scarcely differed from recent weekly numbers. The deaths of infants showed a marked further increase upon the numbers returned in recent weeks; while those of elderly persons showed a further decline, and were fewer than in any week since the first of the year.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

DIPHTHERIA IN RUSSIA.

At a meeting of representatives of zemstvos held not long ago in Kharkow, the following particulars were stated as to the prevalence of diphtheria in Southern Russia. In the government of Voronege (population 1,930,859) the disease made its appearance in January, 1869, and during the eleven years ending 1880, 14,131 cases of the sickness had been reported, of which 5112 were fatal. Diphtheria appeared first in the government of Orel (population 1,532,034) in 1878. There are no data as to the number of cases which have occurred there, but 1302 deaths have been reported. The disease no longer exists in the province. The government of Kharkow was invaded in 1869, or rather the disease was then first recognised. It became epidemic in 1877, and 520 per cent. of the sick died. Diphtheria is still prevalent in the government, but in a less fatal form. Diphtheria appeared in the government of Kursk (population 1,076,988) at the beginning of 1877, and the epidemic was at its height there in 1880. In this year 11,546 persons were attacked with the disease, and 4041 died from it. In the government of Kherson (population 1,027,459) diphtheria has prevailed since 1873. To Jan. 1st of the present year there had been reported 25,980 cases, of which 9342 were fatal. In the province of the Don-Cossacks (population 896,870) diphtheria has not assumed an epidemic character, and the mortality from the disease has been insignificant. The figures as to the population of the several governments mentioned, including the Don-Cossacks, are from the returns for 1858.

NOTIFICATION OF INFECTIOUS DISEASES IN THE METROPOLIS.

The meeting of metropolitan representatives of vestries proposed by the vestry of Kensington for conference on the questions to which we referred in our impression of the 12th March, took place at the Town Hall of Kensington on March 23rd, under the presidency of Major-General Boileau. All the vestries appear to have been represented at the meeting, and the different propositions drawn up by Dr. Dudfield—namely, as to the desirability of a compulsory notification of infectious diseases in the metropolis, an amendment of Section 26 of the Sanitary Act, 1866, and the depauperising of the relief given by the Poor-law authorities to the infectious sick, were discussed and adopted unanimously. A resolution was also carried appointing a deputation to the Local Government Board to submit the conclusions arrived at by the meeting, and ask that the Government should give effect to them by legislation. In the course of the meeting, it is reported that Dr. S. Gibbon, medical officer of health of the Holborn district, maintained that the manner in which infectious diseases should be dealt with would be by drawing a *cordon* around every house where a case of infectious disease should occur. Dr. Gibbon does not seem to have explained that to do this effectually two-thirds of the population of the metropolis would be required to look after the other third.

THE PLAGUE.

The latest news from Turkey as to plague indicates that the disease is still extending in Nedjef and the vicinity. Kufa appears to have been deserted by its inhabitants, and the houses are being subject to disinfection.

In the Gambia, small-pox is stated to be prevailing among the black population; whilst the administrator of the territory reports that, in consequence of the cessation of yellow fever in Senegal, vessels arriving from St. Louis, Goree, &c., are not placed in quarantine at Bathurst if they bring clean bills of health.

A report of Surgeon Glazier on the history of trichinæ and trichinosis has been issued by the American Government. It appears that, judging from the statistics of the medical institutions in the United States where dissections are made, the disease is not common in that part of the world.

Fever having broken out on board the training-ship *Boscawen*, the crew have been sent either to their homes or to the *Warrior*.

THE SERVICES.

ARMY MEDICAL DEPARTMENT.—Surgeon-Major Joseph Watts to be Brigade Surgeon, vice Sampson Roch, granted retired pay; Surgeon-Major St. John Stanley to be Brigade Surgeon, vice John Meane, granted retired pay; Surgeon-Major Charles Moore Jessop to be Brigade Surgeon, vice Charles Carroll Dempster, granted retired pay.

ADMIRALTY.—Surgeon Anthony Gorham, M.D., has been promoted to the rank of Staff Surgeon in Her Majesty's Fleet, with seniority of 23rd ult. The following appointments have been made:—Surgeon Malcolm V. Stace, to the *St. Vincent*, additional, for service in the *Martin;* Staff-Surgeon Thomas L. Horner, to the *Briton;* Surgeon Alfred Patterson, to the *Mallard;* Surgeon Robert F. Yeo, to Malta Hospital, vice Ffrench Mullen; Surgeon Henry B. Collins, to Haslar Hospital, vice Yeo; Surgeon Francis G. Wright, to the *Briton;* Surgeon J. W. Tate, to be agent at Mullaghmore, vice O'Neil; Staff-Surgeon Joseph Wood, M.D., to the *Duke of Wellington*, in lieu of a surgeon, vice Horner; Staff-Surgeon A. Gorham, M.D., to the *Invincible*, in lieu of a surgeon, from date of promotion; Surgeon John Wood to the *Implacable*, vice Patterson; and Surgeon Joseph Crowley, to the *Audacious*, vice Wood.

MEDICAL NOTES IN PARLIAMENT.

Foot-and-Mouth Disease.

IN the House of Lords on Tuesday, Lord Spencer, answering a question put by Lord Lansdowne, explained the intentions of the Privy Council as to the orders relative to foot-and-mouth disease, which expired on the 31st ult.

In the House of Commons on Thursday, the 24th ult., petitions were presented in favour of the Alkali Works Bill from the Lancashire and Cheshire Associations, and against the Bill from owners and occupiers of cement works. For inquiry into the Indian Army Medical Department from L. F. Dickson and F. C. Barker.

On Friday, a petition for alteration of the Alkali Bill was presented from Macclesfield. Petitions were also presented as follow:—From the Irish Medical Association, against the Infectious Diseases Notification (Ireland) Bill; from Irish medical officers of health, for better observance of the Public Health (Ireland) Act, 1878; from dispensary medical officers, Ireland, for alteration of the law relating to vaccination in that country; and from Greenhithe, Brighton, and other places, for the prevention of vivisection. A return of deaths by starvation in the metropolitan district during 1880 was presented on the motion of Mr. John Talbot. Mr. Roger Leigh has, with Mr. Puleston, put down a notice of motion for the rejection of the Alkali Bill.

Fever Hospitals and Convalescent Homes.

Mr. R. Yorke asked the President of the Local Government Board whether, having regard to the statements made to him by a deputation on the 21st ult. on the subject of the prevalence of scarlet fever in the metropolis and the increase of centres of infection, owing to the absence of all provision for the reception of convalescents from that disorder, he would give that question his immediate attention; whether it was the duty of the Local Government Board to make provision for the establishment of convalescent homes in connexion with the fever hospitals of the Metropolitan Asylums Board; whether the existing state of the law admitted of that being done efficiently, and, if it did not, whether he would take immediate steps to obtain by legislation the necessary powers. Mr. Dodson would not fail to give attention to the matter. There was no duty imposed upon the Local Government Board to require the establishment of convalescent homes in connexion with the fever hospitals of the metropolis. Assuming that such homes could properly be considered hospitals for the sick, the Board would have a discretionary power in respect of them. Having regard, however, to the recent action which had been taken to suppress some of the small-pox hospitals, it was not likely that the Board would at this moment meet with much encouragement if it attempted to exercise such a power.

An Unfounded Charge.

In reply to Mr. J. G. Talbot, who put a question to the President of the Local Government Board respecting a charge made at a public meeting against the managers of the Metropolitan Asylum District of negligence in the management of the Small-pox Hospital at Fulham, Mr. Dodson said he was aware that a charge was made at a public meeting against the managers by a gentleman who stated in a letter that he had recently seen the nurses from the Small-pox Hospital at Fulham walking up and down the Seagrave-road in their working costumes among the children of his neighbours. He had since seen a copy of a letter written by the gentleman in question after attending a meeting of the hospital committee in which the whole matter was fully investigated. In that letter he expressed his satisfaction at finding that the persons whom he saw were not, as he imagined, nurses in the employment of the hospital. It was to be regretted that the same degree of publicity had not been given to this retractation as was given to the charge. Mr. Firth explained that he did not read the letter at length. It was one of many letters which were handed up to him as chairman, and it affirmed that the nurses of the hospital had been seen playing with the children in a particular street. An opportunity had not arisen of giving the explanation which was desirable.

On Monday, a petition against the abolition of vivisection was presented from British medical men in Rome. The second reading of the Alkali Bill was deferred to Thursday, as also was the Committee stage of the Blind and Deaf-mute Children Bill, upon which Mr. Paget has given notice of certain amendments.

Animal Vaccine.

Mr. P. A. Taylor asked the President of the Local Government Board whether it is a fact that there is no well-ascertained case of spontaneous cow-pox on record; whether it is a fact that the common practice for many years has been to inoculate the calf with the virus of human small-pox, thus causing, in the words of Sir Thomas Watson, "a vast amount of mitigated small-pox"; whether it is a fact that within the last few years the mortality from small-pox at the Hague and other cities in Holland and Belgium (whence he proposes to obtain fresh lymph) has been enormously large; and whether he will bring in a Bill to abolish compulsory vaccination. Mr. Dodson said he did not know what his hon. friend would consider a "well-ascertained case of spontaneous cow-pox," but cases of outbreaks of the disease amongst cows were specifically mentioned in the treatises on the subject, as well as in the evidence before the Select Committee in 1871. He was informed that it was not a fact that the common practice had been for many years to inoculate calves with the virus of human small-pox. He had no statistics as to the mortality from small-pox in Belgium, but in Holland the mortality in the epidemic of 1870–72 was very large indeed. There was nothing to show what proportion of the cases were vaccinated, and it must be borne in mind that neither in Belgium nor in Holland was vaccination compulsory. He had no intention to bring in a Bill to abolish compulsory vaccination.

On Wednesday, a petition for inquiry into the subject of butter adulteration was presented from the Grand Jury of Cork. Mr. Dwyer Gray moved the second reading of the Infectious Diseases Notification (Ireland) Bill, which was accepted by the Government, on the understanding that it might be amended in Committee; and the Bill was read a second time without debate.

The Hampstead Hospital Case.

On Thursday Mr. Firth asked the President of the Local Government Board whether the statement made at the last meeting of the City of London Union that the costs of the recent Hampstead Hospital case amount to £40,000 to £60,000 has any foundation in fact, and whether he has now ascertained what is the estimated amount of such cost; and whether there is any and what statutory authority enabling the Metropolitan Asylums Board to expend the money of London ratepayers in such litigation, or upon what ground such expenditure is approved by the Local Government Board. Mr. Dodson said he did not know what the costs of the Hampstead Hospital case amounted to, but there could be very little doubt that the statement referred to in the question was a considerable exaggeration. The Metropolitan Asylums Board were advised that they had what was called a good defence, and probably if they had not taken the steps they did they would have been held to be greatly to blame. M. Firth said he should repeat the first portion of his question, and was proceeding to say that "we had to pay the money," when he was called to order.

Cholera from Butterine.

Mr. O'Shaughnessy asked the President of the Board of Trade if his attention had been called to the fact that an outbreak of cholera which has occurred in the town of Chicago has been attributed by physicians of that town to the use of butterine, into the composition of which lard enters largely, and to the statement made by these physicians that the process of making butterine does not require so high a temperature as to kill the germ of disease in lard; and whether the Government will take measures of precaution, by inspection of butterine and other similar commodities into this country, to prevent the dissemination of disease by their use. Mr. Chamberlain replied that he had been furnished with a copy of an American newspaper, and in one amongst a number of anonymous paragraphs he found a statement similar to that conveyed in the question. The statement, however, did not give the names of the physicians to whom this opinion was attributed, and there was no means of ascertaining whether they were persons of authority. He believed the medical opinion in this country was adverse to the opinion those anonymous physicians had expressed. As to the last part of the question, he had no evidence whatever which was trustworthy to show that any diseases were disseminated by butterine or other similar commodities.

Bequests and Donations to Medical Charities. Sir H. Watson Parker, late of East Sheen, Surrey, bequeathed, at the death of his widow, £1000 to the Richmond Hospital, £500 each to the Cancer Hospital and the Consumption Hospital, Brompton, the Richmond Dispensary, and the Royal Kent Dispensary. The Cumberland Infirmary, the Cumberland and Westmoreland Convalescent Institution, the Carlisle Dispensary, and the Whitehaven and West Cumberland Infirmary receive each £250 under the will of the late Mr. W. M. Bell of Sackville-street, London. Major F. W. Cartwright bequeathed £100 to the Northampton Infirmary.

A member of the New York Legislature has introduced a Bill to inflict a penalty on the keepers of hotels and boarding-houses who use oleomargarine, or other imitations of butter, without prominently displaying an announcement that they do not supply genuine butter.

CATGUT LIGATURE IN THE TREATMENT OF ANEURISM.

To the Editor of The Lancet.

Sir,—Might I be allowed a few words in reply to Mr. Lane's letter in your last issue on the subject of the catgut ligature. It will be remembered that out of the three cases referred to by Mr. Lane the vessels in two instances were found patent at long intervals after the operation, while the third vessel was found closed. It would be quite out of place to rediscuss the general points suggested by these cases, and I would wish to allude merely to Mr. Lane's explanation of the unequal results. Mr. Lane says that it is clear to him "that the two failures arose from the ligature not being effectually applied." In these two cases a double hitch was used, followed by a single hitch; in the third case two single hitches were adopted. I quite agree with some of Mr. Lane's remarks anent the difficulties of the double hitch knot, and with those also made by Mr. Barwell in The Lancet for March 5th. It seems to me that the use of this knot may prove in some cases inefficient; and in a series of experimental ligations of arteries made in the post-mortem room I certainly failed in one case to divide the inner coats with this particular knot, and used a good deal of force to effect that end in other cases.

But this possible source of failure does not affect the present cases. I presume that the efficacy of a ligature regarded simply as a *knot* tied to close a vessel depends mainly upon two factors—firstly, the possibility of its not slipping when once tied; and, secondly, its power of dividing the inner and middle coats when drawn tight. Now, of the two knots in question, I should imagine that the double hitch knot was by far the less likely to slip, and yet this knot was applied in the two cases where the vessels remained patent. With regard to the other point, in one of these two cases the coats were divided; in the other they were not. So far as I can see, therefore, the question remains somewhat in the same position as before.—Your obedient servant,

Frederick Treves.

Gordon-square, W.C., March 29th, 1881.

THE BIRMINGHAM HOSPITAL FOR WOMEN.

To the Editor of The Lancet.

Sir,—I regret to say that no other writer has been so anxious as I have been to give to Dr. Keith the full credit which is due to him for our present low mortality in ovariotomy. But Dr. Keith's cases can hardly be called hospital cases—at least, he does not publish them as such,—and, therefore, I was not including his results in the comparison.

At present we nearly equal his last results, and in friendly rivalry I hope to excel them—and all the more credit to him.

I am, Sir, yours &c.,

Birmingham, March 24th, 1881. Lawson Tait.

UNQUALIFIED PRACTITIONERS AND PRIVATE DISPENSARIES.

To the Editor of The Lancet.

Sir,—In a recent number you drew attention to an inquest on a case in connexion with my dispensary. The accompanying extract from the local paper which first reported and commented on the case will show that the circumstances were strangely misrepresented. All the explanations which you say ought to have been forthcoming were fully and satisfactorily stated to the coroner at the inquest, though not reported, and all the arrangements which you very properly urge were in existence at the time, and are so now. The message to visit the patient was only delivered a few hours before her death; and the circumstances of the case being suspicious and mysterious it would have been highly improper to have given a certificate, even had I seen the girl myself. I am, Sir, yours truly,

March 23rd, 1881. A. Kisch.

⁂ We gladly insert the above letter, feeling satisfied that in this instance reasonable endeavours are made to have patients attended by the principal, or, in his absence, by a qualified friend. The publication of the extract would make too great a demand on our space.—Ed. L.

IRELAND.

(*From our own Correspondent.*)

THE Secretary of the Public Health Committee of the Corporation of Dublin has recently made a report on the system adopted at Steevens's Hospital for the disinfection of clothing, bedding, &c., used by patients suffering from infectious diseases. On the occasion of his visit to the hospital there were twenty-seven patients in the fever ward all suffering from scarlatina, and all of them members of the constabulary. Ten patients were in each of the two wards, the cubic space for each being under 600 ft. There was no convalescent ward, and acute and convalescent cases consequently occupied the same apartment. These constabulary patients on admission wear civil clothing, of which they do not possess more than one suit, but a loose overcoat is supplied by the constabulary authorities, and this is worn by the patients during convalescence; so that during the desquamative stage they must resume their civil clothing, and continue to wear it until their return to the constabulary depôt. It follows from this that the disinfection of these patients' clothing during their illness is rendered practically ineffectual, and that their garments are likely to carry infection to others. It is further stated that the attention of the governors of this hospital was several months since directed to the danger that must result from mixing infected with disinfected articles, and that the suggestion was disregarded. The Public Health Committee have strongly recommended the governors to provide proper measures of disinfection on their own premises, to separate infected from disinfected clothing, and not to permit the men to leave the hospital wearing the clothes which had been subject to the risk of infection.

Dr. MacCabe, Local Government Board Inspector, in a recent report on the condition of the North Dublin Union for the six months ending 31st December last, states that its crowded condition had probably exercised an unfavourable influence upon the sanitary condition of the workhouse during the period referred to. Typhus fever prevailed extensively amongst the lower classes of the city, and many destitute persons were admitted to the workhouse when suffering from premonitory symptoms of typhus. It frequently occurred that applicants for admission were not aware of their condition, and the symptoms they presented were not sufficiently advanced to warrant the medical staff in transferring them to a fever hospital until some days after their admission; and while such persons remained under observation in the workhouse it is probable that zymotic diseases were by them communicated to other inmates.

At the close of the past year there were 1022 inmates in the Richmond District Lunatic Asylum, and no increase in the accommodation for lunatics has been called for since 1874, during which year it was raised from 1040 to 1100 beds. The admissions in the past year have been 420, or 15 less than in 1879, but the number admitted for first attacks has been exactly the same in both years; whilst the admissions of relapsed cases have been only 65 in the past year, against 80 in the year preceding. One hundred and sixty-seven were discharged cured (or $39\frac{320}{420}$ per cent. of recoveries on admissions, and $11\frac{1091}{1419}$ on total number in asylum), and 81 improved, while the unimproved or incurable were 10. The mortality amounted to 138, all from natural causes, a number equal to $32\frac{360}{420}$ per cent. on admissions, and $9\frac{1029}{1419}$ on total in asylum. Thoracic affections formed a large proportion of the causes of death—viz., 66, while cerebral and cerebro-spinal affections produced but 24 deaths—a circumstance which has not escaped the notice of Dr. Lalor, the resident medical superintendent, who observes that with those labouring under a mental affection of which organic disease of the nervous centres is by many supposed to be the chief factor, the deaths from cerebral and spinal affections are comparatively few. The pathology of insanity, he adds, is, in truth, only in its infancy, and the part which the blood circulating in the brain plays in cerebration, and the variations produced in the phenomena of mind by diversities in the qualitative and dynamical conditions of that fluid, appear to him to present a large field for investigation, which has by no means been largely cultivated.

During the quarter ended December 31st last there were registered in the 801 registrars' districts in Ireland 27,582 births, a number equal to an annual birth-rate of 20·7 in every 1000 of the estimated population, and 22,226 deaths, representing an annual rate of 16·7 per 1000. The birth-rate in Ireland was under the average of the rate for the corresponding quarter of the previous five years to the extent of 2·9 per 1000 of the population; while the death-rate for the quarter was below the average of the fourth quarter of the five years 1875–9 by 0·3 per 1000.

PARIS.

(*From our own Correspondent.*)

THE protests against the dismissal of the religious communities from the hospitals have been met by a counter-protest from those who are in favour of the measure. This document is worded as follows:—"Monsieur le Directeur Général—At the present moment, when the question of the *laïcisation* of hospitals is attracting attention, we believe that we accomplish an act of honesty in stating the result of our experience. After having directed in other establishments services which were placed in the hands of the sisters, we are now attached to hospitals organised after the new system, which has been in vogue at Laennec for the last two years, and at La Pitié for six months; and we are pleased to acknowledge that we are satisfied with the intelligence and devotion of the *personnel* under our orders. It is therefore possible to affirm, from a knowledge of facts, that all the professional qualities necessary for the performance of their duties may be met with in lay superintendents and their subordinates." The signatures which follow are eight in number, comprising four professors of the faculty, MM. Verneuil, Peter, Brouardel, and Ball, and four *agrégés*, MM. Cornil, Damaschino, Le Groux, and Nicaise. Whether they will be able to rally any more adherents remains to be seen, but as yet they only form a numerically insignificant minority. The editor of the *Progrès Médical*, however (whose journal has become, with the *Tribune Médicale*, the official organ of *laïcisation*), is thankful for small mercies, and attaches the greatest importance to this new declaration, which is, indeed, probably the only justification the Assistance Publique can bring forward of the action they intend to pursue. Of course, the question of liberty of opinion is imported into the matter; and it is nominally for the sake of religious and political liberty that a competent staff of nurses, courageous enough to suffer for their faith, are to be replaced by more docile instruments. At the Municipal Council an appalling instance of the proselytising tendencies of the Sisterhoods was related by M. Quentin. At the Necker Hospital a nun was conversing with a young servant. "Do you go to the mass?" "No; my masters have forbidden me." The nun thought this was damnable, and tried to prevent the servant returning to her employers—tried to turn her from her duty. "We cannot permit this," added the speaker. Such an anecdote tells much more against the master who perverts a girl from what nine Frenchwomen out of ten would consider a religious *duty* than against the nun; and it affords a good idea of what such men understand by the religious liberty hereafter to be enjoyed in hospitals.

The annual fancy-dress ball for the patients of the Salpêtrière took place last week, and a full report of the proceedings was given in an evening paper, *Le Temps*. As on the last occasion, no attacks of any kind had occurred for some time past, the patients being too busy in the preparation of their dresses to carry on their usual performances. "Why," inquired the *Temps* reporter of Dr. Legrand du Saulle, "if the *fête* procures a month's repose, is it not adopted as a means of treatment—treatment by pleasure?" "The expense is too great," was the reply. The entertainment to-night costs more than a thousand francs!

Paris, March 30th, 1881.

EXTENSION OF RAINHILL ASYLUM.—At the forthcoming annual meeting of magistrates a motion will be submitted for the extension of Rainhill Asylum, to admit a thousand more patients, and £120,000 will be borrowed for the purpose.

THE six European countries which forbid the importation of American pork are Spain, Portugal, Italy, France, Greece, and Switzerland.

Medical News.

Indian Medical Service. — The following is a list of candidates who were successful at the competitive examination held at Burlington House on Feb. 14th :—

1. H. I. Griffiths.
2. F. D. C. Hawkins.
3. A. Milne.
4. J. A. Cunningham.
5. A. G. E. Newland.
6. H. C. Hudson.
7. P. Mullane.
8. A. Silcock.
9. R. I. Baker.
10. J. W. Rodgers.
11. R. G. Cooper.
12. M. B. Braganza.
13. H. W. Stevenson.
14. W. A. Corkery.
15. A. J. L. Patch.
16. R. Ross.
17. S. T. Avetoom.
18. C. A. Adams.
19. J. F. Maclaren.
20. J. K. Kanga.
21. E. R. Da Costa.
22. A. J. O'Hara.

Apothecaries' Hall. —The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on March 24th :—

Callaway, James, City-road.
Moore, Alexander Matthew, Newcross-road.
York, Thomas Hutten, Brady-street, Bethnal-gren.

The following gentlemen also on the same day passed the Primary Professional Examination:—

William Isaac Haddock and Frederick Lucius Nicholls, Charing-cross Hospital; Reginald Whiteside Statham, St. Thomas's Hospital.

A cottage hospital has been opened at Llandrindod Wells, Radnorshire.

Cambridge University. — On March 24th the degree of Bachelor of Medicine was conferred on Frank Montagu Pope, Magdalene.

The late Mr. Courtauld of Gosfield Hall, has, we are informed, left his medical attendant, Mr. Taylor of Bocking, Essex, the sum of £500.

Mr. C. E. Hobbes of the Alcester and Evesham Unions, has received, for the fourth time, the Government grant for efficient vaccination in his districts.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* The Lancet *before 9 o'clock on Thursday Morning, at the latest*

Bevan, W. Ll. P., M.B., C.M., has been appointed House-Surgeon to the Wallasey Dispensary [not the Dorset County Hospital, as announced in our last].

Blandford, J. W., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Norton District of the Stockton Union.

Carden, G. A., M.R.C.S.E., L.S.A.L., has been appointed Honorary Medical Officer to the Branch Dispensary of the Cheltenham General Hospital, vice Spurway, resigned.

Cathcart, C. W., M.B, F.R.C.S.E., has been appointed Lecturer on Anatomy in the Royal College of Surgeons, Edinburgh, vice Handyside, deceased.

Chapman, J. H., M.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer to the Hospital for Incurables, Dublin, vice Peele, deceased.

Churchill, J. F., L.R.C.P.L., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer for the Second District of the Amersham Union.

Davies, D., M.R.C S.E., L.S.A.L., has been reappointed Medical Officer of Health to the Bristol Port Sanitary Authority.

Fentem, P. S., M.D., M.R.C.S.E., has been reappointed Medical Officer of Health for the Northern Division of the Bakewell Rural Sanitary District.

Hayward, J. R., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the All Saints' District of the Maldon Union.

Jeffreys, R., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Bampton and Walton District of the Chesterfield Union.

Keene, F., L.R.C.P.L., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health for the Aylesbury Rural Sanitary District.

Knox, J., M.D., L.R.C.S.Ed., has been reappointed Medical Officer of Health for the Southern Division of the Bakewell Rural Sanitary District.

McGeagh, W., M.D., M.Ch., M.R.C.S.E., has been appointed Honorary Assistant Medical Officer to the Ladies' Charity and Lying-in Hospital, Liverpool.

Meeres, E. E., M.D., M.R.C.S.E., L.S.A.L., has been appointed Physician to the Plymouth Public Dispensary, vice Thorold, resigned.

Malley, A. C., M.B., M.Ch., has been appointed Medical Officer for the Munslow District of the Ludlow Union.

Morcom, —, L.R.C.S.Ed., L.S.A.L., has been reappointed Medical Officer of Health for the Luton Rural Sanitary District.

Newsholme, A., M.B., M.R.C.S.E., has been appointed Surgeon to the City Dispensary, vice J. A. Kingdon, F.R.C.S., resigned.

Parsons, F. J. C., L.R.C.P.L., M.R C.S.E., L.S.A.L., has been reappointed Medical Officer of Health to the Bridgwater Port Sanitary Authority.

Births, Marriages, and Deaths.

BIRTHS.

Dawson.—On the 24th ult., at Hyde-park-gardens, W., the wife of Yelverton Dawson, M.D., of a daughter.

Lawrence.—On the 24th ult., at Chesfield, Hadlow, Kent, the wife of H. M. Lawrence, L.R.C.P.Ed., L.R.C.S.Ed., of a son.

Lukis.—On the 26th February, at Barrackpore, Calcutta, the wife of Surgeon C. P. Lukis, Bengal Medical Service, of a daughter.

Scott. — On the 28th ult., at Lancaster House, Lincoln, the wife of W. E. Scott, L.R.C.P. &c., of a daughter.

Wallace.—On the 21st ult., at Cleckheaton, Yorkshire, Constance, the wife of Edward J. Wallace, M.D., of a son.

MARRIAGES.

Bothamley—Dunn. —On the 26th ult., at St. Antholin's Church, Nunhead, William Parkinson Bothamley, M.R.C.S.E., L.S.A.L., of Donington, Lincolnshire, to Elizabeth Ann, eldest daughter of W. Dunn, Esq., of The Newlands, Peckham-rye.

Eddison—Dougill.—On the 29th ult., at the Parish Church, Almondbury, near Huddersfield, John Edwin Eddison, M.D., of Park-square, Leeds, to Elizabeth, eldest daughter of the late John Dougill, of Finthorpe, Almondbury.

Maxwell—Ritchie. —On the 21st ult., at 8, Whitehouse-terrace, Edinburgh, by the Rev. W. L. Riach, Charles M. Maxwell, M.R.C.S.E., L.S.A.L., of Broomieknowe House, Lasswade, N.B., to Rossie Milne, fifth daughter of the late George Ritchie, of Edinburgh.

Nesbitt—Gresham.—On the 23rd ult., at Derrylin, County Fermanagh, Dawson Nesbitt, M.D., of Cambridge-place, Hyde-park, to Emily, second daughter of the late William Henry Gresham, of Glenwood, Lucan, County Dublin.

Thom—Aitken.—On the 24th ult., at Oaklands Crieff, N.B., by the Rev. J. R. Omond and F. C. Monzie, Alex. Thom, jun., M.A. St. And., M.B. & C.M. Ed. (son of Dr. Thom, of Ivy Lodge, Crieff), to Helen, daughter of Mark Aitken, of Oaklands.

Vacher—Braidwood.—On the 30th ult., at St. Mary's, Hornsey-rise, London, Francis Vacher, F.R.C.S.Ed., Medical Officer of Health for Birkenhead, to Isabella, younger daughter of the late Rev. J. Braidwood, M.A. No cards.

DEATHS.

Levick. — On the 23rd ult., at West Ham, Essex, George Levick, M.R.C.S.E., L.S.A.L., in his 40th year.

Merriman.—On the 24th ult., at West Lodge, Putney-common, after a few hours' illness, John Merriman, M.R.C.S.E., L.S.A.L., Apothecary Extraordinary to the Queen, aged 80.

Webb.—On the 29th ult., at The Vicarage, Heckmondwike, Yorkshire, Edward Charles Webb, Surgeon, second son of the Rev. George Mower Webb, B.A., Vicar of Heckmondwike, aged 36.

Whately. — On the 24th ult., at Gainsborough, Torquay, Edward Whately, M.R.C.S.E., aged 61.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, April 4.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.
ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.
MEDICAL SOCIETY OF LONDON.—8.30 P.M. The President (Dr. Broadbent) will exhibit a Patient suffering from Double Facial Paralysis.—Dr. W. H. Day, "On Tubercular Meningitis and the Mode of Treatment."—Dr. R. J. Lee, "On Cutaneous Diseases in Infants and Young Children."

Tuesday, April 5.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 3 P.M.
ROYAL INSTITUTION.—3 P.M. Professor Edward A. Schäfer, "On the Blood."
PATHOLOGICAL SOCIETY OF LONDON.—8½ P.M. The following specimens will be shown:—Carcinoma and Adeno-fibroma of Breast, Hyaline Myxoma, Odontoma, Nasal Epithelioma, &c. (card); Cranium and Brain of Hydrocephalic Adult; Case of Pulsation in Hepatic Region (living specimen); Aneurism of Pulmonary Artery (card); Dermoid Tumour of Soft Palate; Case of Lupus (living specimen); Abscess of Liver following Dysentery; Unreduced Dislocation of Patella (card).
SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND SCIENCES.—Mr. William Westgarth, "On Trade Relations between Great Britain and her Dependencies."

Wednesday, April 6.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.
ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.
ST. MARY'S HOSPITAL.—Operations, 1½ P.M.
KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at 1 P.M.
LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.
GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.
ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Lumleian Lectures: Dr. Southey, "On Bright's Disease."
HUNTERIAN SOCIETY.—7.30 P.M. Council Meeting.—8 P.M. Dr. Hughlings Jackson will exhibit Cases of Disease of the Spinal Cord.—Dr. Port, "On a Case of Disseminated Sclerosis."
EPIDEMIOLOGICAL SOCIETY.—8 P.M. Deputy Surgeon-General Joseph Ewart, "On Scrofula, Tuberculosis, and Phthisis in India."
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by the President, Drs. Godson and Cory, and Mr. Alban Doran.—The Discussion on Dr. Barnes's paper "On Missed Labour" will be resumed, after which "A Case of Delivery through an Imperforate Vagina," by Dr. Heywood Smith, and other communications.

Thursday, April 7.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.
ROYAL INSTITUTION.—3 P.M. Mr. H. H. Statham, "On Ornament."

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

FOOD AND DISEASE.

DR. SEATON, Medical Officer of Health for the borough of Nottingham, gave last week to the members of a local temperance society an interesting lecture on diseases spread by means of food. Such diseases he classed into the parasitic and the zymotic. He sketched the history of the trichina spiralis, and referred to the communication of Dr. Wortabet, published in THE LANCET of March 19th, as containing a striking illustration of the efficacy of thorough cooking of food in destroying the parasite. Dr. Seaton then alluded to the cases of pork infection that had recently occurred at Welbeck and at Nottingham. These had no relation to the disease of which he had been speaking—trichinosis. They were caused by most minute microscopic particles closely resembling other microscopic particles which during the last few years had been shown to be the cause of some of the zymotic infectious diseases, as, for instance, the relapsing fever of man, the anthrax of cattle, which, in the form of woolsorters' disease, affected man also. The lecturer set forth more in detail the relation of the spirilla to relapsing fever and the probability of its being connected with its causation. He also spoke of the identity between the bacillus anthracis and that of woolsorters' disease as a thing which, if not absolutely proved, was in the highest degree probable; and described the process of fermentation and the nature of disease germs (a subject treated of in another column).

DISPENSARY PRACTICE.

To the Editor of THE LANCET.

SIR,—I can fully endorse the opinions of L.R.C.P. relative to the above, but there are also other snares which the unwary purchaser should be guarded against. Many, if not the major portion of dispensaries, are started and pushed on by qualified men, ne'er do weels in the usual routine of regular practice, with the view of showing good receipts, and as soon as their desideratum is obtained, of selling them at the best marketable value. Such, oftener than not, rapidly fall off in receipts. I myself became entangled in partnership in a similar undertaking, and now find partner is oftener more fit to be doctored than to doctor, through a considerable *penchant* for alcoholic stimulants. The consequences likely to accrue from such conduct one does not care to contemplate, especially when a good sum has been paid down for the privilege of joining another in such rough-and-ready work as dispensary practice.

I am, Sir, yours faithfully,

March, 1881. L.R.C.S.I.

THE SO-CALLED SMALL-POX IN CHICKENS.

MR. WILMOT H. T. POWER, B.A., M.R.C.S., communicates to "Hardwicke's Science Gossip" the following note:—"In Mauritius large numbers of the chickens are reduced to mere skeletons, with a dry scaly eruption on the skin, leaving more or less bald patches, especially about the head and neck. I found this was due to the presence of lumbrici in such numbers that the interior of the intestines was so irritated as to be as red as a soldier's tunic; emaciation and eruption were due simply to starvation. At one station we kept our poultry in a large enclosure covered over with a net, and taking care none but clean water, and frequently changed, was given them. We had no disease, and fine chickens. About 100 yards off at a lighthouse, it was always present, but the poultry there drank from a very dirty small pool. I feel inclined to say Mauritius had degenerated from being the land of the dodo to the land of the lumbrici."

Mr. Partridge.—Thanks.

Norman.—No.

Mr. Jos. Moore.—It is purely a matter of agreement.

"THE CASE OF PROBABLE POISONING BY COLCHICUM."

To the Editor of THE LANCET.

SIR,—In a letter published in your issue of March 19th, Mr. Linnington Ash, referring to this case, speaks of muscular twitchings as "the distinctive symptom of the influence of colchicum." Will you allow me, through your columns, to ask Mr. Ash on what authority he founds this assertion? I find no mention of this symptom in such works on Toxicology as I have access to. I believe cases of colchicum poisoning not unfrequently end with convulsions immediately preceding dissolution; but, as a general rule, nervous symptoms of any kind other than these are rare. Mr. Ash, however, appears to found his opinion that this case was not one of poisoning by colchicum on the fact that no muscular twitchings appeared in the early part of the case.

Your obedient servant,

G. M. WASSE, M.R.C.S. ENG.

Knighton, Radnor, March 25th, 1881.

TREATMENT OF FRACTURED PATELLA WITH HIDES' PATENT PERFORATED FELT SPLINT.

To the Editor of THE LANCET.

SIR,—The success I have had with Hides' patent felt splint in the treatment of bow-legs in children has induced me to dip with it more deeply into surgery in the treatment of fractured patella as a fixture for the knee-joint. Although this fracture is not a very common occurrence, and seldom comes within the scope of the general practitioner, yet in hospitals it is common enough; and even there some difficulty exists in keeping the fragments in position, which in all cases is all that is necessary. Every surgeon knows very well the treatment recommended in this fracture, and I believe will admit the difficulty of producing a case of union, at most only ligamentous to a more or less extent.

I claim for Hides' patent splint an improvement (if only in comfort to the patient) on Malgaigne's treatment with hooks, which up to the present is the only sure means of keeping the fragments in undisturbed position, but without the pain and inconvenience of having four hooks inserted into the bones through the integument, a great discomfort to the patient, if not requiring removal altogether after a short time by the irritation they produce. Besides, Malgaigne's hooks if they can be borne are only useful in cases of transverse fracture. Should it happen to be oblique and partly vertical, in three portions they become perfectly powerless, in which case my treatment will answer quite the same.

This splint, when properly applied, should not be attempted for a week, or until the inflammation subsides, and then in two parts, anterior and posterior, meeting within half an inch at both sides. They should be shaped on a sound limb, about the same size, taking particular care while doing so that the felt in its soft condition is pressed with the two hands firmly around the patella, so as to drive the synovial fluid puffed out during extension back into the joint, when it will take the exact mould of the patella and retain it when cool. Should the splints not fit the knee for which it is intended, it should be warmed before a fire and held in its position on the knee for two or three minutes. When the parts are properly moulded and trimmed, it is only necessary to line them with coarse flannel or saddle lining serge, and have a one and a half inch strap with buckle attached above and below the knee, about six inches apart; then the joint will become firmly fixed, without undue pressure. The patella is surrounded as in a socket, with no possible chance of the fragments separating. Another great advantage is obtained by the even pressure on the quadriceps, the splint extending for at least six inches from the centre of the patella, thus preventing their action by nervous twitching during sleep.

The patient may get about after three weeks and walk with a fixed knee, continuing to wear the splints as long as may be considered necessary.

I am, Sir, yours &c.,

Chelsea, March 28th, 1881. HENRY FISHER, M.D.

DRUGGISTS' CHARGES.

THE *Bristol Mercury* inserts the letter of a physician to a London contemporary, who complains that a druggist had charged a patient—a respectable but poor married woman for whom he had prescribed gratuitously—eighteenpence for a box of ointment. The physician sees in such charges one of the great obstacles to the poor getting proper supplies of drugs, and therefore one of the explanations of their being driven wholesale to public charities. There is some truth in this. The charges are absolutely prohibitive in many cases, and just in those cases where the supply of drugs is most urgent—where drugs, in fact, come to be something very like food. But this is an old complaint, and the druggists are more conservative in their system of charges than medical men.

CHRYSOPHANIC ACID IN PSORIASIS.

To the Editor of THE LANCET.

SIR,—As I was the first investigator of the effect of chrysophanic acid in psoriasis, may I be permitted to offer a comment on the ingenious suggestion offered in your columns of last week by "A Student of Materia Medica." He suggests that the effect obtained in Professor Charteris's experiment with the drug shows that the drug acts constitutionally as well as locally, and thus seeks to explain why it is that in Professor Charteris's experiment the ointment cured also that half of the body to which it had not been applied. The suggestion is well worth considering; but I may remark that, although a "one-sided" application of chrysophanic acid ointment has been often tried, the effect noted by Professor Charteris had not, so far as I am aware, been observed before. Then, again, the constitutional effects of chrysophanic acid (administered, it is true, in persons not the subjects of psoriasis) have been carefully investigated by a very able and well-known observer, Mr. Ashburton Thomson, who administered the drug in doses of, I think, ten grains in one hundred cases, and who found it to act only as an emetic purge. Now, since I first brought under notice the remarkable effect of chrysophanic acid ointment in psoriasis it has been used all over the world and by the most competent observers, and its effects have been recorded in almost every medical journal, British and foreign, and no one has spoken of emesis or purging as having ever followed its external use.

Now, let it be supposed that some one should advance that the external use of tar in psoriasis should depend in some degree on its "constitutional" effects, then I could answer him I am in a position to say that I have administered tar internally *ad nauseam*, and even so long (a month or more) that I felt constrained to employ it no longer, and yet I have found that thus employed it has no influence whatever in the amelioration of psoriasis. I do not apprehend that chrysophanic acid administered internally would have any better effect on psoriasis. Still, so far as I know, the experiment has never been tried, and it is quite possible that it might succeed.—Yours obediently,

March 28th, 1881. BALMANNO SQUIRE.

To the Editor of THE LANCET.

SIR,—A Medical Student in Materia Medica, Glas. Univ., has drawn attention to an interesting point in a case of psoriasis, which Dr. Crocker brought before the Medical Society of London, which he had treated, one extremity with chrysophanic acid—one drachm to the ounce—the other with turpentine. We know that the system is affected by drugs—viz., by the inunction of mercury it is soon affected, but it is hardly probable that the small dose of chrysophanic acid that would enter the system from the inunction in Dr. Crocker's case would affect the system so much as to relieve the opposite extremity so thoroughly. It seems to me more likely that the turpentine relieved the eruption in his case, as I have repeatedly used the pure spirits of turpentine of the strength of one and two drachms to the ounce of vaseline with marked good effect in psoriasis; and the relief of the opposite extremity to that treated by chrysophanic acid was in all probability due to the turpentine. As Dr. Crocker justly remarks, almost any outward irritant will benefit the affection, but, at the same time, these cases require careful internal treatment; as in my experience they only return to us again after a longer or shorter period, for, as the patients often say, "it only drives the eruption in." There is no doubt whatever that chrysophanic acid is a valuable drug in carefully chosen cases of psoriasis.

I am, Sir, yours truly,

Sackville-street, W., March 29th, 1881. JAMES STARTIN.

To the Editor of THE LANCET.

SIR,—The point raised by a Glasgow Student in your last issue is, I think, worthy of attention. He informs us that Dr. Charteris believes that the acid acts constitutionally as well as locally, and he furnishes us with facts that seem to prove that theory. The theory is, I believe, erroneous, because during several years in which I acted as clinical clerk at the Western Infirmary and Dispensary for Skin Diseases, Glasgow, no such effects were observed.

Dr. McCall Anderson often presented the acid to one side of the body, while to the other thymol or other agent was applied, the result being that the side to which the acid was applied always improved much more than the other, which, indeed, in some cases did not improve at all. Thymol, it may be remarked, was shown to have a slight effect either when used alone or to one side of a patient to whom the acid was prescribed for the other side.

Dr. Radcliffe Crocker's case, in which benefit was derived from turpentine, is not thus to be explained, but it is probable that the turpentine has some curative effect.—I am, Sir, yours, &c.,

Southport, March 28th, 1881. CHARLES PEMBERTON, M.B.

MEDICAL CHARITIES AND PRIVATE PRACTICE IN GLASGOW.

To the Editor of THE LANCET.

SIR,—Kindly allow me space for a few remarks suggested by the experience of a few months' practice in Glasgow. I refer, first, to "medical charities," particularly out-door dispensaries. That dispensaries have a demoralising effect upon the industrial classes, and a prejudicial effect on private practice, I think that there is not much doubt. For instance, I was called upon by a tradesman's wife, with her daughter, who had an abscess in the thigh. I advised that it be poulticed for two days, when, very likely, I should have to open it. This was agreed to, but she wanted to know how long she should poultice. Instead of returning to me, however, which she could do in about three minutes, the two went to the dispensary of one of our infirmaries, which is about eight times the distance, stated her case, and that she had gone there to get the operation done free; but the surgeon, who possibly from his private practice is acquainted with the tendencies of such people, sent them back to me, remarking that I had advised quite rightly. On the following day they went to the dispensary of the other infirmary, and there the operation was performed. This was all to save a shilling, which could well have been afforded, several members of the family being pretty regularly employed. Very rarely indeed do we hear of a dispensary surgeon doing as that gentleman did. On the contrary, I know a woman who took her child to the dispensary. The surgeon on duty attended that child afterwards privately in the same case, and rendered his account, which was shown to me. This woman was well connected socially. The well-to-do tradesman, or his wife, the spendthrift, and the respectably-dressed stranger are classes well represented at the dispensary. They are encouraged to go there, and they tell you that they "see the head doctor at the infirmary," and "get advice free." We private practitioners well know how we are called upon by those who "have no money," those who "are to pay on Saturday," but who never again turn up, and by those (to whom we gladly give gratuitous advice)—the deserving poor. What are the true objects of "medical charities?" And why are we licensed to practise while we find our interest very frequently injured by the same class of medical gentlemen, if we are unfit to do all for our patients that may be done in the dispensary?

Secondly, your leading article in THE LANCET of February 26th, pp. 339-40, should, by certain readers, be considered along with the fact that the druggists are largely opposed in their business by medical men. In one street alone in Glasgow, for instance, there are eight drug shops, two only of which are druggist's shops, and this proportion does not vary much in many of the other localities. It is not uncommon to find the doctor himself, even on a Sunday, and sometimes during public worship, behind his counter ready to retail cigars, sweets, hair-oil, &c., so that, *primâ facie*, the druggist has some reasons why he should treat a patient when asked to do so. I speak of Glasgow and its suburbs alone, however. It would appear that medical men are too plentiful. The unkind and even dishonest treatment I received the other day at the instance of a medical gentleman of some standing, in the case of a patient I was attending, who asked and received advice of the former in opposition to mine, would lead one so to think. Can a remedy to the existing evils not be found, as now the question of medical reform is receiving attention, by lengthening the curriculum, and enforcing a higher standard of education, thereby improving the morals and professional accomplishments of the profession, while reducing its numbers relatively to the rapid yearly increase? Benefit would accrue to all concerned, not excepting the schools.—I am, Sir, yours, &c.,

March 2nd, 1881. R. W. E.

HOMERTON SMALL-POX HOSPITAL.

To the Editor of THE LANCET.

SIR,—The clerk who copied my statistical report concerning the Homerton Small-pox Hospital has made several mistakes in the latter portion, and I shall therefore feel obliged if you will print the following as a correction, beginning at the words "The cases," in col. 1, page 517: "The cases per 1000 population per annum in the ten years 1871–80 were as follows:—In the streets around the hospital 12·0, in those situated with a quarter of a mile radius in front and at the sides of the hospital 9·2, and in the other small houses 5·8 per 1000. The number of deaths from small-pox in 1861–70, after allowing for the deaths of residents removed to the Highgate Hospital, was 173, which gives an annual death-rate of 0·167 per 1000 population for the whole district. There were 15 deaths registered within the quarter of a mile radius, which, with 3 added for the proportion removed to the Highgate Hospital, gives 0·264 per 1000, against 2·45, or nearly ten times as many, in 1871–80 as in 1861–70. The proportion of deaths in the quarter of a mile radius in 1861–70 to the total deaths in these years was 10·4 per cent., whilst in 1871–80 it was 18·3 per cent. of the whole, or nearly twice as many, showing that the inhabitants of these streets suffered to a much greater extent as compared with the rest of the district in 1871–80 than in 1861–70.

I remain, Sir, yours faithfully,

JOHN W. TRIPE, M.D.,

Medical Officer of Health for the Hackney District.

Hackney, March 28th, 1881.

"HYGIENIC INFLUENCE OF HOUSE PLANTS."

To the Editor of THE LANCET.

SIR,—Will you allow me a remark on the above subject, on which there is a note in THE LANCET of March 19th. House plants may be of advantage to a phthisical patient in two ways—1st, directly by purifying the air; 2nd, indirectly, by indicating the purity or foulness of the air in which they are kept. It is a matter of everyday experience that many plants will not live on the products of gas and other combustion, nor will they thrive in dark and sunless aspects; and therefore the "enthusiastic floriculturist," while suiting his rooms to his plants, was doing unwittingly what was the very best thing for himself. I do not intend to deny any importance to the direct action of plants, but their indirect action should not be lost sight of, and in the case in point it is possible that as good results might have been obtained with the four children who died (provided they were in as good general circumstances as marriage at twenty-three years implies) if they had kept no plants at all, but merely paid scrupulous attention to the hygiene of ventilation and sunlight, or if they had been treated by a physician of whom it is related that on being called to a case of phthisis he used to begin treatment by breaking a pane out of the bedroom window with his stick.

I am, Sir, yours, &c.,

Torquay, March 22nd, 1881. A. HAIG, M.B. Oxon.

CAUSATION OF THE DIFFERENCE OF EARLY SYPHILITIC ERUPTIONS.

To the Editor of THE LANCET.

SIR,—I would be greatly obliged if you would publish this letter in THE LANCET correspondence column. I have for a long time sought to find whether there are any theories concerning the causation of the difference of the earlier syphilitic eruptions—why some should be papular and others erythematous. Is it due to idiosyncrasy or to variety of infection? By variety of infection I mean whether one form of rash has appeared more frequently from primary or secondary infection.

Again, does the difference in any way affect prognosis? Should any of your readers be able to direct me to any author who treats these points or can give his own knowledge, I for one, and I believe many others, would be glad to read his letter.

I am, Sir, yours truly,

March 27th, 1881. M.R.C.S.I.

AN APPEAL.

To the Editor of THE LANCET.

SIR,—Will you allow me space in your valuable journal to draw the attention of subscribers to Epsom College to a very deserving case. In September, 1879, Mr. G. S. D. Harris, a much respected practitioner of Leighton Buzzard, died suddenly, leaving a widow and ten children almost totally unprovided for, seven of whom are very young and entirely dependent upon her. The fourth son, Hamilton George Harris, is a candidate for the coming May election for a foundation scholarship. This is his second and last chance, as his age excludes him from another election.

I had the pleasure of an intimate friendship with the late Mr. Harris, and can bear testimony to the assiduity and kindness with which he carried out a most laborious but poorly paid practice. He died literally in harness, a victim to hard work and insufficient opportunities for relaxation in the effort to maintain a numerous family. The case is known to several influential persons.

I shall be happy to receive proxies and furnish any further particulars on application.—I am, Sir, your obedient servant,

CHAS. GROSS,
Medical Superintendent, St. Saviour's
March 30th, 1881. Infirmary, Walworth.

Mr. A. Smith should consult some skilled ophthalmic surgeon, *not* an optician.

Mr. Boon (St. Kitts).—The paper has not come to hand.

Mr. Sinclair.—Opinions differ as to the effect of flowers in bedrooms. The question is not yet sufficiently discussed.

Dr. G. W. Balfour's letter will appear in our next.

ERRATUM.—In Mr. Lowe's letter, published in the last number of THE LANCET, the temperature stated to be sufficient to destroy adult septic monads was erroneously put at 104° Fahr. It should have been 140° Fahr.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Althaus, London; Dr. Stephenson, Earlsland; Mr. Jessett, Erith; Mr. Atthill, Faversham; Mr. Dodd; Mr. Rendle, London; Mr. Wasse, Knighton; Mr. Lowndes, Liverpool; Dr. Handfield Jones, London; Mr. T. Green Birmingham; Mr. A. Smith, Liverpool; Dr. Fisher, Chelsea; Mr. A. Kisch, London; Mr. R. V. Ash, London; Dr. Drysdale, London; Dr. F. Taylor, London; Mr. L. Tait, Birmingham; Dr. Cassidy; Mr. Oswald, Camberwell; Mr. Steele, Walworth; Dr. Herchmer, Fort Saskatchewan; Mr. Wolverson, Alfreton; Mr. Pinkerton, Southport; Mr. Haward, London; Mr. Wheeler, Swindon; Dr. Cory, London; Dr. Uhthoff, Brighton; Dr. Tripe, London; Mr. Wright, Pendlebury; Mr. Gick, Dublin; Mr. T. Croonian Lectures

ON THE

INFLUENCE OF THE CIRCULATION ON THE NERVOUS SYSTEM.

Delivered before the Royal College of Physicians of London,

BY WALTER MOXON, M.D. LOND., F.R.C.P.

LECTURE II.—PART I.

MR. PRESIDENT AND GENTLEMEN,—In my last lecture I endeavoured to describe means whereby the entry and exit of blood to and from the interior of the cranium are so arranged as to favour the maintenance of a constantly sufficient supply to the brain, whilst obviating ill results of undue stress of blood; I then passed on to the effects produced when great atmospheric pressure forces blood into the closed cavities which contain the nervous centres; and, finally, I digressed to point out the weakness in the circulation of the lowest part of the spinal cord which arises through its more precarious supply from above and want of reinforcement from below. Whilst upon the arterial supply to the spinal cord, it occurs to me to observe a point which has struck me forcibly in reading descriptions of experiments made for the purpose of tracing the course of fibres in the cord, because the mode in which the arterial supply may influence the results of such experiments seems apt to escape notice, and this may be a part of the reason why different observers differ in their results. Thus, for instance, in one of the experiments made by a great master in this branch of investigation, a comparison is set up between the effects upon the sensibility of posterior nerve-roots, when incisions are made near together across the posterior columns above and below a single pair of roots, and the effects produced when similar incisions are made far apart, including five posterior roots between them. When such incisions are close together sensation in the single pair of roots between is lost; when the incisions are far apart, the roots not only retain their sensibility, but appear rather more sensitive than natural. If we bear in mind the posterior spinal arteries, and the mode of their reinforcement by occasional branches on the nerves, we shall see that when the incisions are close together, the posterior spinal arteries above and below are severed, and the small segment drained of its blood, so that surely insensibility would arise from this cause alone. If, on the other hand, the incisions include as many as five nerve-roots between them, there is a very great probability indeed that a large reinforcing artery will enter the posterior spinal in so great a length, and thus maintain a blood-supply. But it may be asked, will such an explanation serve to show why the sensibility is increased? We must not, however, assume that evidence of unnatural tenderness is a proof of increased sensibility; this no doubt is not the case. I have now under care in Philip ward a man who has paralysis and insensibility to touch in his right leg, but nothing the matter with his left leg. In this man a pinch which causes only a smile when applied to his sound limb, produces a cry and a request against its repetition when it is applied to the limb which cannot feel a touch or localise the pinch. Hence signs of pain do not prove sense of touch, and the conductors of normal sensibility cannot be traced by signs of pain. In this man the skin of the affected limb is pinker and thicker than the skin of the sound limb. This far from unprecedented case shows that we may expect proofs of unnatural sensitiveness to coincide with considerable anæsthesia; and the unnatural sensibility to pain in the posterior roots may itself be taken as some evidence that the normal sensibilities of the part were reduced. In following out the points that have arisen with reference to the circulation of the spinal cord, I have digressed considerably from the main line of my argument, which is bent on inquiring into the soundness of the view which teaches that congestion of the brain is an essential or primary disease.

And now I will return to the effects of caisson pressure upon the brain, if one can so speak when we find that the pressure had no effects at all upon the brain except to give a general feeling of buoyancy, which was, I think, very properly ascribed to the greater quantity of oxygen that entered the blood under high pressure. The caisson pressure offers us an example of active and unobstructed congestion of the vessels of the brain with oxygenated blood, no complication with a venous state of the circulating fluid being present, so that it may be described as a forcible arterial congestion, without impediment to free exit of the blood—an active arterial congestion purely affecting the blood-supply, and free from complication with disorders of the nervous tissue.

The familiar phenomena of strangulation and of obstruction of the jugular veins causing forced delay of exit of the venous blood should not be allowed to complicate the question I am approaching. But as the sensations accompanying venous obstruction in the neck give rise to a very general bias in favour of the notion of cerebral congestion at large, it may be well for me to state the bearings of this subject on the special question whether congestion of the brain arises independently as a distinct form or as several distinct forms of disease. It would be scarcely possible for me to mention all the many modes in which venous congestion of the brain is constantly brought before us in forms more or less pure. Perhaps the subtlest of the causes of such congestion is that which has been well investigated in the study of school diseases. When children bend over low desks during their lessons, a proportion of them are observed to suffer from headache, and some become faint, and some bleed at the nose; and such results may be ascribed to cerebral congestion. But in using such an expression we must notice that the meaning of it covers at least three distinct things. The ill effects which come about through lowness of the desks in schools are set down in detail by Virchow—first, to the mental strain of the learners; second, to occasional check to respiration during close attention; and third, to obstruction of veins by bending the neck. But each of these things is quite different from the others in its mode of operation—widely different indeed; and each in its own way appeals for its special means of relief. Mental over-strain is cerebral exhaustion; lack of respiration is carbonic acid poisoning together with deficiency of oxygen; and compressed jugulars give delayed exit of venous blood and consequent venous congestion. The term "congestion of the brain" has been given in a general way to these rather complicated conditions, and there is no harm in such a use of the term, unless it induces us to forget the several distinct causes which combine to produce the ill results ascribed to it, and in the term "congestion of the brain" to lose sight of the mental exhaustion and carbonic acid poisoning. Indeed, if we wish to ascertain the effects of obstruction of the jugular veins and retention of venous blood, we must choose some more pure example of such obstruction. I will not enter more fully into the effects of impeded flow in the jugular veins than is necessary to define its relation to the "congestion of the brain" of authors with which I have to do. Such obstruction may be acute or chronic, and may vary in degree in either case from slight obstacle to absolute closure. Many observations of the extent of effects produced by check to the flow in the jugular veins have led me to the conviction that venous obstruction is borne with so much impunity when it is certainly present and severe that one must not suppose such obstruction to be inducing serious results in cases where evidence of its existence is wanting or trifling.

When speaking of obvious causes of obstruction to the current in the jugular vein, I refer in particular to cases of prolonged paroxysm of whooping-cough, or of the cough of emphysema, and to cases of tumour compressing or involving the jugular vein. When a person is in a seizure of either of the forms of protracted cough which I have mentioned, the evidences of venous obstruction and imperfect aeration of the blood become very apparent, often painfully so, and yet cerebral disturbances but very rarely show themselves. I have been impressed by the small number and slight degree of complaints of cerebral symptoms in such cases. Twice only have I known persons affected with old bronchitis, and habitually almost cyanosed, to stagger and fall in the extreme height of their paroxysms of cough. The description given by their friends was of extreme blueness and turgescence of veins when the staggering occurred, so that cyanosis must have largely shared in its causation. Everyone must have seen the veins rise on the forehead, and a dusky colour suffuse the face of persons coughing violently, when meantime nothing noticeable happened to the comfort of the brain. What I am seeking thus to establish is the proposition that congestive strangulation of veins is borne with impunity up to visible and obvious extents, and therefore symptoms cannot be ascribed to it when the visible and obvious conditions of venous overfulness are awanting. Also, I believe that general experience will be with me in recalling how, in examples of tumours in the cervical region pressing upon the jugular veins, and even involving and closing one of them, the comfort of the brain is surprisingly little invaded. One of the most clear-headed and intelligent patients I have seen had the neck enlarged so that shortly below the chin it exceeded the girth of the head and face, and these were livid with venous obstruction; yet she denied to my questions every sign of cerebral annoyance. When such ascertained venous congestion, producing obvious retention of blood, fails to cause serious symptoms, unascertained and unproven congestion cannot be called in as a supposition to explain serious symptoms.

I have so far endeavoured to adduce examples, first of extreme arterial intracranial blood pressure, and second of visible and obvious intracranial venous blood pressure, so that the absence of serious ill effects under conditions of ascertained great or evident blood pressure within the skull may be within our minds in approaching consideration of the disorders described under the name of congestion of the brain.

There is still one step remaining before I can proceed to the task of examining into the clinical symptoms described as due to this disease, and that is to make clear how far it is possible to show by post-mortem examination that a person has died from congestion of the brain. We must spend some time upon this question, because following and supporting the clinical descriptions of congestion of the brain we find a morbid anatomy of congestion of the brain. Just as after the clinical description of acute pneumonia, we find the morbid anatomy of acute pneumonia, and the morbid anatomy of acute pneumonia does verify and explain the presence and the symptoms of pneumonia up to a certain point, failing only in showing why that particular person died at that particular time, and leaving it to clinical observation to answer that question, which is the vitally important question in each case. The post-mortem examination of pneumonia never tells us why that particular death occurred, but it leaves us in no doubt about the characters of the case; one can be quite sure that pneumonia did exist. But will any morbid anatomy of congestion of the brain afford us the same kind of proof, or do anything of the kind? The question is, Can you in any individual case prove by post-mortem appearances that death was caused by congestion of the brain, or even that a state of congestion of the brain or overfulness of its bloodvessels preceded death? I believe these questions must be answered firmly in the negative. In establishing such a negative one has to meet with a very strong prejudice, rooted in the most tenacious grounds, the grounds of convenience and of ancient and universal acceptance. After examining a body dead from brain symptoms, when all you were able to see in your examination was only that the veins were very full of blood, it is very convenient to be able to say that death was caused by congestion of the brain, and it sounds much better skilled witness than to say that death was caused by insensibility; so that the doctrine of congestion of the brain is convenient, and the universality of its acceptance may be illustrated by the naïve earnestness with which authors of great works adopt it; one author of a great work says, on one page, that patients never die in the first stage of congestion of the spinal membranes, and on another page he says that post-mortem shows in the first stage redness of the membranes; but if they do not die how is the redness known? It is very difficult to deal with a delusion thus deeply rooted in faith and prejudice, a delusion which is so much favoured by occasional very striking appearances at imperfectly conducted post-mortems. Thus, in the Clinical Society's Transactions there is a very remarkable spinal case, probably a case of acute myelitis, but introduced to the Society as congestion of the spinal membranes, and, indeed, the membranes were seen to be frightfully congested. But Mr. Hilton pointed out long ago the necessity of observing whether the cervical veins are divided before you make a remark upon the congestion of the veins of the nervous centres; and, indeed, if we don't divide these veins we will be sure to see frightful congestion when we look at the membranes of the brain and spinal cord; but the observers of this case only opened the cranium and spine.

I mention these examples only to illustrate how readily the mind of a physician adopts on insufficient evidence the assumption of a congested state of the brain. But in some of our most justly and highly valued text-books we find amongst a series of excellent, learned, and ably written articles on particular diseases, that a long chapter on congestion of the brain finds a place, and this chapter gathers groups of symptoms of a disease called congestion of the brain, and collects signs of morbid anatomy of the disease so named, and this gathering of symptoms includes a sweeping together of all such things as are obscure and associated with stupor, and have an acute course, and the collection of anatomical signs includes a sweeping up of all the marks of change in the bloodvessels or texture of the brain, however evidently chronic and ancient. And the collection of chronic and ancient changes stands there to the gathering of acute and obscure symptoms as the morbid anatomy of a definite fatal disease—congestion of the brain.

And so in our great books we find this chapter on congestion of the brain made up of obscure fragments out of the history of all sorts of diseased states. In the work which contains the chapter we generally find that there was already a chapter on epilepsy, and another on sunstroke, and another on alcoholism, and then in the chapter on congestion of the brain we have a treatise on epilepsy that is not quite epilepsy, and sunstroke that is not quite sunstroke, and alcoholism which has changed so that it is now deserving to be called not alcoholism, but congestion of the brain. But when we ask for evidence that these hazy states of quasi-epilepsy, quasi-sunstroke, &c., are really due to congestion of the brain, we meet with a very difficult state of affairs, very prejudicial to clear dealing with the subject; I mean we are met with a foregone conclusion, a sort of traditional certainty about the matter, as if you ought not to ask for evidence. Believing as I do that there is no such fatal definite disease I find this a very unsatisfactory state of affairs, and I was very glad to see in a recent and very valuable work on medicine, that the author of that work, himself a pathologist of great experience in morbid anatomy, speaks thus of this topic of "congestion of the brain:"—"So many nervous phenomena are commonly referred to congestion or anæmia of the nervous centres that we can scarcely presume to pass over them in silence." One could have wished that the conviction thus evinced had led this distinguished physician to deal more summarily with a doctrine he thus confesses himself forced by common reference to touch upon.

As one finds categorical descriptions of a morbid anatomy of this disease, congestion of the brain standing on the highest authority in our text-books, I cannot ignore them, or merely say there are no such signs, but must deal with the several anatomical appearances which are advanced as showing post-mortem that the brain was congested during life, my position being that there is no valid evidence of the kind. So that I must now trouble you with an examination of the post-mortem appearances which are alleged to prove congestion of the brain. We find writers giving four conditions as showing congestion. I will take them *seriatim*. The first condition advanced is a swollen state of the brain, so that it seems, after removal of the calvaria, almost too large for the cavity which contained it. The dura mater seems tightly stretched over it, and on reflecting this the convolutions appear broad and flattened, and the sulci less obvious. Now here we have evidence of swelling of the brain. But as to our power of drawing any conclusion from such a swollen state, it is curious that the description makes no allusion to hypertrophy of the brain, which is treated of elsewhere in the same work, and is known only by its causing a general enlargement of the whole brain. I have never seen such hypertrophy, but the flattening described has very frequently come under my observation, and my impression is that in no instance did I ever meet with such flattening unless some obvious cause of expansion of the brain has been present, in the form usually of an increase of the intraventricular fluid, or else of apoplectic bleeding, or of tumour, in which case the swelling and flattening are more localised. The next evidence mentioned is the distension of veins and capillaries with blood; the veins are tortuous and varicose; the grey matter dark. Both this and the white matter show abundanse of bloody points and gorged vessels, and this description finishes by saying: "It is extremely difficult to draw the line, and say what is morbid and what is consistent with health." Now, it is better—nay, it is necessary—to say firmly that it is not only extremely difficult, but it is simply impossible, to draw the line, and say what is consistent with health. Indeed, by bringing in the idea of health when the person is dead we confuse the issue, and I should not mention this except to remark that the visible state of affairs at the post-mortem examination is the point that concerns the morbid anatomist, and not the inferential state of affairs during life and health. For this is not any longer at all in the question, which question is whether the mode of dying, the position of the body after death, or the manner of making the inspection will not determine the appearance of extreme overfulness of the vessels in the brain of the dead person independently of the conditions which were antecedent to all this and led to his having so to die. Can we infer from the amount of blood in the brain after death the amount during life? Perhaps one could not find a more decisive answer to this question than the answer given by Kussmaul and Tenner. These observers were investigating the effects of ligature of the cervical vessels, and it was most important for their purposes that they should be able to estimate the resulting anæmia of the brain by post-mortem examination. Their experiments were very numerous. They were testing the results of a simple mode of treatment of the brain; they had it in their power to place the bodies in any position they liked, or in any circumstances of temperature, &c., and they knew accurately the conditions actually allowed. This is what they say as the result of their investigations:—"We could never deduce any results from the post-mortem examinations undertaken with a view to determine the state of fulness before death of the most important parts of the vascular system—viz., the arteries and arterial capillaries, and even in the most favourable instances when similar inquiries were directed towards the veins, our results could only be looked upon as approximate. It appears, therefore, to us to be especially necessary to study carefully the state of the brain circulation in asphyxia, narcosis, intoxication, etherisation, &c., in the living animal according to Donders' method—that is, by insertion of a watch-glass into the skull."

Now, if this is the result when the conditions before and after death were determined and known, how can it be said that the amount of blood found after death in the human brain will show the amount present before death when the conditions before and after death were undetermined and unknown? Again, why should we take the amount of blood found post mortem in the brain as a criterion of the amount present there during the disorders that led to death, when the amount of blood present in other parts after death cannot be taken to indicate the amount present before the act of dying? It may be necessary here to examine the exact bearing of evidence in some cases where we appear to accept fulness of blood after death as evidence of fulness of blood before dying. Let us take the most striking example we can choose in which we might be led to suppose that we are in the habit of drawing such a conclusion, and thus do ourselves an injustice. Now, it is true that where organs are situated close to seats of long-continued and positive hæmal obstruction—as for instance, the liver, or stomach, or lungs—when seen after death from heart disease the amount of blood in the vessels of these parts forms a striking feature at the post-mortem examination. We observe great overfulness of the veins, and we know that overfulness existed during life. But it is not because of the amount of blood found there after death that we know there was so much blood there during life. For the amount of blood present post mortem is really only the result of the mode of dying. Death in mitral disease is due to stoppage of the heart under intense engorgement, so that the great vessels near the heart are very full in the moment of death; and remain so afterwards, in the ordinary position of the body, and from this cause there is much blood in the wall of the stomach, and meantime our knowledge of the ischæmic state produced by the cardiac obstruction makes us aware that the same condition existed during life, also the presence of excess of tough mucus or superficial ulceration may give evidence to the same effect. But as to the particular question whether a great amount of blood in the stomach wall after death will serve to show that there was a great amount of blood in it before dying. If we were asked that question we must, I believe, answer it firmly in the negative. Great amounts after death may have been preceded by great amounts before the person began to die, as heart disease shows us, but the stomach may be deeply congested by sudden disease or accident causing asphyxia merely as a manner of dying, so that you cannot, because the stomach is purple after death, say that it was so before dying commenced. The importance of this subject, in many aspects of medical practice, induces me to follow it out fully, because one finds it on all hands assumed, and by the highest authorities stated, that redness of the brain shows congestion, or even inflammation of it. Thus, in a very thorough and able article on tubercular meningitis, we find it said of the membranes of the brain that they show "that great sign of inflammation, redness," and even in works devoted specially to morbid histology the same fallacy is encouraged. Rindfleisch, speaking of acute hyperæmia of the brain, says: "A slight flush of the medullary substance, a faint tinge of red mingled with the usual grey hue of the cortex cerebri, must be taken as very significant indications; where even these are lacking we must not jump to the conclusion that they did not exist during life." Of course the question is not of jumping to negative conclusions, but founding sound positive conclusions, and nothing can be more misleading or wrong than such a statement as that a faint tinge of red mingled with the usual grey hue of the cortex must be taken as a very significant indication. One is tempted to think the author had not looked carefully into the variations of colour to be observed in brains as they ordinarily appear before the pathologist. Faint tinges of red are constantly to be seen in the brains of persons dead from indifferent diseases, and the blood is often very curiously and irregularly distributed under entirely indifferent conditions, marbling and mottling the grey matter with pink and purplish tinges. A section of the cortical grey matter, or more especially of the corpus striatum and thalamus, will convince anyone of this in almost any case. So also it is misleading to speak of "that great sign of inflammation, redness" as appearing post mortem. During life, redness, when associated with swelling, heat, and pain, is at one with these associates in proving the existence of inflammation; but after death the redness which was due to the enlarged scope of vascular play ceases, because vascular play has ceased with life. The consequence is not doubtful, and it is quite certain that after death the redness goes from inflamed and congested parts. Such serious issues may turn upon this point, that I think it very necessary to clearly recognise that no degree of redness, or pinkness, or overfulness of blood about the brain or its membranes can prove that there was any morbid state of the circulation within the head before the act of dying. Death by asphyxia increases the amount of blood in the head, but a dependent position of the head after death, if only for a short time, will cause a similar increase. It should be taught that it is a sign of ignorance to say in a coroner's court that congestion of the brain was found on post-mortem examination to be the cause of a person's death.

Passing on now to the next point advanced as morbid anatomy of cerebral congestion, one finds the description lays down tortuosity and varicosity of the larger veins of the brain as evidence of such congestion. Now, if by this is only meant the bending of the veins through overfulness, it is but a sign of overfulness, and Kussmaul and Tenner have disposed of overfulness for us; but if it is really meant that the veins are varicose, I think moderation of the description is desirable, at least in the several thousands of inspections conducted by me I never saw a varicose vein upon the brain. It is true that we often find the veins thickish and opaque near their endings, but the veins have their share in the general thickening of fibrous parts within the skull in old age. I will take this thickening along with *l'état criblé*, which is given as another proof of congestion of the brain; *l'état criblé* is a perforated look of section of brain usually in the corpus striatum, and due to cutting across of dilated channels, which are dilatations of the channels in which the arteries run. The thickish vein and perforated-looking appearance are signs of senile wasting of the brain such as results in elderly people from a hard life, and results sometimes in younger people from a still harder life in which they may have poisoned themselves with alcohol, or by too much continued stress of emotional existence have been their own poison to the same effect. In the process of ageing the brain shrinks, both as a whole, so as to leave space between it and the skull, and interstitially so as to allow spaces to form around its internal vessels, giving *l'état criblé* on section. The skull is thus not sufficiently filled, and then everything movable and within reach is drawn upon to fill the vacuum. The call tells first upon the cerebro-spinal liquid, whose function is to supplement the brain in filling the skull. But when the natural amount of this liquid is insufficient the blood must enter, and be retained to fill the rest of the space. But the excess of venous blood thus retained lends itself to encourage the growth of the lower forms of tissue, especially the connective tissues; so that, as a consequence, you get thickening of the membranes, and this appears especially in what I called the tidal area, where the locking system in the veins tells most effectively, and where Pacchionian glands in time appear, the vein walls thickening a little in the meanwhile. Even the cranium itself, having its dura mater kept full of blood, thickens inwards, so tending to reduce the cavity. But as to the question before us, which concerns itself only with the disease called congestion of the brain, what we have to see is that all these things are most gradual and slow effects of chronic shrinking of the brain, producing secondary effects most gradually and slowly. So that it all comes gradually about as a progressive system of events constituting the character of a period of life, and explaining the creeping approach of age, but in no way serviceable to furnish explanation of sudden insensibilities, and other phenomena described as acute diseases, under the title of congestion of the brain.

And, now, let us look at the remainder of the morbid anatomy advanced in support of the supposition that sudden serious illness is caused by rush of blood to the head. The description lastly sets down as such evidence a quantity of blood or hæmatin around the vessels, twisted and varicose capillaries, evidence of bursting of capillaries, orange-coloured spots and specks of crystalline hæmatoidin, and especial stress is incidentally laid on the observation of blood pigment around the vessels in the brains of excitable lunatics. Now, there is no doubt that blood pigment is very frequently met with about unsatisfactory looking capillaries when the brain of any adult is searched through with care. At least I was led to this conclusion when, during the first few years of my office as pathologist to Guy's Hospital, I used to take away about a cubic inch from the neighbourhood of the island of Reil in every brain I inspected. For after the vessels of these portions of brain were washed and examined, the result was such as to assure me that when anyone over twenty-five years of age replies in a satisfied way to an inquiry as to his health, he expresses the truth of the matter only so far as he is aware, and his answer overlooks the condition of a considerable number of the capillaries of his brain, much in the same way as it overlooks the state of his skin at some pimple or perchance the caries of some tooth. In fact, were a pathologist with a great microscope to spy through all our brains as we sit here in states of satisfaction, he would certainly see a great deal in the way of tortuous capillary and dots of yellow pigment—a great deal that under the microscope would look very alarming. But so constant are moderate amounts of the changes now in question that one cannot justly ascribe any peculiar significance at all to moderate degrees of them; and surely experience would suggest great caution in allowing importance to the observation of blood pigment in the brains of excitable lunatics. Because if the amount of pigment was little it is not more than other people have; but if it was much, then would not the question arise whether the excitable lunatics had struck their heads, or perchance received blows in the course of the care they required to have taken of them. Numerous broken ribs are not infrequent signs in asylum anatomy. A great deal of blood may be effused in the brain through blows from which people recover. A fatal hæmorrhage into the brain is nearly always a large hæmorrhage, and many people recover from blows which more or less approach a fatal result without reaching it. Those who recover must then have the moderate amounts of hæmorrhage. I have seen the middle and anterior lobes of the brain stuck fast to the skull and imbedded in old yellow pigment and hæmatoidin, showing that most extensive crushing of the brain had been survived. So that sharp blows or falls upon the head such as everybody not more than commonly fortunate has to suffer at least several times in his life are not without effect in doing more or less to throw out spots of blood here and there for future microscopic observation, to regard as evidences of congestion of the brain. But, besides accidental injury, there are other mischances to the blood through fever with purpuric tendencies, or through morbid states of the blood generally, and to these rather than to any such disease as congestion of the brain or determination of blood to the head, we must be prepared to ascribe those changes in the capillary vessels, and the little spots of blood pigment that are found on careful microscopic examination of the brain. They are the results of all the accidents, little and great, that have made their mark, large or small, on the brain in the course of its life. It must be remembered that blood pigment is probably never removed when once it has been formed, but it remains at the spot as a permanent register of the accident that produced it. I trust I have sufficiently shown that we have no anatomical grounds for believing that there is any malady whose cause is overfilling of the vessels of the brain with blood.

ON

ANÆMIA.

Delivered before the Royal College of Physicians,

BY SIDNEY COUPLAND, M.D., F.R.C.P.,

PHYSICIAN TO THE MIDDLESEX HOSPITAL.

LECTURE II.—PART II.

Idiopathic Pernicious Anæmia: Illustrative Cases—Analysis of the Different Forms of the Disease—The term "Idiopathic" not applicable to a considerable proportion—Preponderance in the Swiss Cantons (especially Zurich) largely dependent on Mode of Life—Influence of repeated Pregnancies, Gastro-intestinal Disease, Hæmorrhage, Malaria, and Nervous Disorders in determining a "Pernicious" Anæmia—Pathogeny: Is it due to increased Blood Destruction or want of Blood Formation?—Changes described in Blood and in Bone-marrow (Pepper, Cohnheim, Osler)—Its Relations to Leukhæmia, to "Pseudoleukhæmia," to Chlorosis.

I WILL now proceed to detail to you the leading features of cases of idiopathic anæmia which have occurred in the Middlesex Hospital during the past ten years. They are not numerous, and they do not comprise all the forms in which this condition occurs, but they will serve to illustrate my subject.

CASE 1.—This has already been published,[1] and I will content myself with a brief abstract of it. S. D——, aged twenty-seven, a pale, delicate-looking, but not emaciated woman, married five years, but childless, was admitted under the care of Dr. Greenhow on Sept. 7th, 1871, complaining of pain between the shoulders, palpitation, great weakness, vertigo, depression, and coldness of the extremities. The skin was as white as wax, and there was a faint jaundiced tint of the conjunctiva. The lips were colourless, and the tongue pale, clean, and moist. There was a loud double murmur over the præcordial region, having a friction-like character, and a maximum intensity at a point just inside and a little above the left nipple. There was no enlargement of the liver or spleen, but slight epigastric tenderness attributed to frequent retching. The pulse was 128, very weak, small, and compressible; respiration shallow; no cough; temperature 100·4° F. The urine was acid, of sp. gr. 1013, free from albumen or bile-pigment. Her history was as follows. There was no tendency to hereditary disease; she had had the usual diseases of childhood, and was always rather delicate and subject to palpitation. The catamenia appeared at fourteen, and since then she had had more or less menorrhagia and leucorrhœa. She never, however, had any serious illness till about a year ago, when she began to suffer from diarrhœa and vomiting, with occasional vertigo, but did not complain of pain after food, nor did she vomit blood or pass any per rectum. The palpitation now became worse, and was accompanied with pain between the shoulders. These symptoms continued for two or three months, when she got better; but three months afterwards was attacked in the same manner, with the addition of a slight yellow tinge of the skin and conjunctiva, and was again laid up for two months. After this a second remission occurred, and she remained comparatively well till two months before admission, when the old symptoms returned. The progress of the case was marked by increasing debility, constant nausea, and occasional vomiting. On Sept 20th there was some diarrhœa, but neither at this nor at any other time was blood observed in the motions. The pulse, respiration, and temperature remained much the same throughout, the latter never exceeding 102°, and only once descending as low as 98·8°. On October 3rd she vomited during the afternoon and frequently during the night. The sickness continued, and she sank exhausted on Oct. 5th. At the post-mortem examination minute ecchymoses were found studding the inner surface of the dura mater, and a small quantity of slightly turbid fluid coated the surface of a portion of the hemispheres and dipped in between the convolutions. The brain itself was completely bloodless. There were also ecchymoses on the pulmonary pleuræ, a few old adhesions, and some recent lymph on the right side, but the lungs were healthy. The pericardium contained three ounces of fluid and showed no traces of inflammation. Not more than an ounce of thin, pale, and watery blood could be obtained from the heart and large vessels, and that was perfectly fluid and did not coagulate. All the other viscera were examined, but showed only intense anæmia. Dr. King, in his comments on the case, raised the question of the anæmia being caused by a derangement of nervous function, supposing, from the analogies supplied by the act of secretion, that the sympathetic system directly controls the act of blood-formation. He draws a parallel between such cases and those of Addison's disease, where the symptoms are so similar (except the pigmentation), and where the existence of a nerve-lesion is more evident. It is interesting to find Addison stating that "in the case last examined the heart had undergone such a change" (he is speaking of its fatty degeneration), "that a portion of the semilunar ganglion and solar plexus, on being subjected to microscopic examination, was pronounced by Mr. Quekett to have passed into a corresponding condition." But I do not know of any other facts which can be called in support of Dr. King's reasonable hypothesis.

---

[1] By Dr. R. King, Brit. Med. Journ., Nov. 25th, 1871, p. 613.

CASE 2.—Emma H——, aged twenty-nine, unmarried, a domestic servant, admitted under the care of Dr. Greenhow, April 20th, 1875. One of her sisters had died of consumption. She herself had enjoyed fairly good health till six weeks before her admission, when she began to feel very tired at her work, which was hard. She had also suffered from occasional vomiting and attacks of fainting, whilst becoming, in addition, paler, and attacked with shortness of breath on slight exertion. She was well nourished, but very anæmic, the skin having a somewhat tawny tint, especially about the neck, axillæ, and back. The mammæ were ill-developed. The heart's action was exaggerated, impulse diffused; visible pulsation of carotids; radial pulse, jerking, 120. A soft systolic murmur was audible at the base of the heart, and a well-marked bruit in the jugulars. There was slightly impaired resonance at the anterior apices of the lungs, and wavy respiratory murmur, but elsewhere the breath sounds were normal. No enlargement of liver or spleen. Urine: sp. gr. 1025, acid; no albumen. The blood showed a deficiency of red corpuscles, but no excess of leucocytes. The predominant symptoms were vomiting and diarrhœa, accompanied by increasing languor and debility. The temperature was irregular, the highest point reached being 102°, on the evening of admission, and the general range being between 100·2° and 99°, the evening temperature being mostly lower than the morning. The pulse ranged between 120 and 140, and was very feeble, during the last two days maintaining the more rapid rate, whilst the temperature fell to 97·8°. She sank exhausted on May 2nd. At the post-mortem examination the general surface and the mucous membranes were noticed to be extremely pale, the skin of neck, axillæ, and groins being of a pale-brown colour. The mammary areolæ were not pigmented, and no pigmentation occurred at the root of the nails. There was a fair amount of subcutaneous fat, and much in the omentum. The pleural and pericardial sacs contained dark-coloured serum. There were a few subpericardial ecchymoses at the back of the heart, which was fairly covered by fat, its muscular substance being pale and flabby. Both sides contained much thin fluid blood, whilst in the right ventricle a thin, pale, soft clot was met with, diminishing towards auricle and pulmonary artery. The lungs were pale and bloodless, slightly puckered and indurated at apices, the posterior part of each lower lobe being engorged with frothy serum. The liver and kidneys were anæmic, but healthy. Spleen small, pale, and tough. Suprarenals natural. Semilunar ganglia appeared healthy, but were not examined microscopically. In the stomach the mucous membrane in the pyloric region was thicker and firmer than elsewhere, white, perfectly smooth, and free from mammillation. The only remark I would make upon this case is that it might as well be described as a case of fatal chlorosis, which it resembled in the mode of its onset, and that the predominance of gastric symptoms was very marked, again suggesting a neurotic basis for the whole disease.

CASE 3.—Henry A——, aged forty-three, single, a potman, admitted under Dr. Cayley's care on Sept. 18th, 1878. His mother had died of consumption, but he had a healthy brother and sister. When ten years of age he was ill with rheumatic fever for eight weeks, and had been subject to rheumatic pains in all parts of the body. For the past three or four weeks he had, however, been getting more sallow and short of breath, and within the past week his feet began to swell. In spite of his occupation he drank moderately. When admitted he was extremely prostrate, but free from pain. His skin and mucous membranes were intensely anæmic, and there was considerable œdema of the lower extremities. There were bronchitic râles in the lungs. The heart was not enlarged, and no bruits were audible; spleen and liver not enlarged. There was some diarrhœa. The urine was of sp. gr. 1015, acid, but free from albumen. After a week's rest the œdema had almost subsided, the diarrhœa ceasing also. The temperature varied slightly, being often above 99°; on Sept. 26th it was 101·8° in the morning. On the night of Oct. 9th he was attacked with temporary aphasia and slight deviation of the tongue to the *left*, but no other paralytic symptom. The temperature was then 100°; pulse very weak, 120; heart's action tumultuous, and a systolic murmur appeared at the base. Next morning he could speak well, and the tongue was protruded straight. Temperature 101°; pulse 108. But the same afternoon he had a similar seizure, when his speech became indistinct, the tongue deviated to the left, and slight paresis occurred on the left side of face and left arm. Temperature 103°; pulse 120. The paretic condition passed away in a few days, but he became more prostrate and drowsy, and died on Oct. 13th. At the post-mortem examination no lesion was found in the brain, which was very anæmic. Hæmorrhagic foci were found in the retinæ. There were some old pericarditic adhesions, much fat on the surface of the heart, and extreme fatty degeneration of its muscular fibres. There were a few subpleural ecchymoses on the surfaces of the lungs, which were engorged in their dependent parts. The liver was paler than natural, spleen pale but soft; pancreas and suprarenal capsules healthy; the kidneys were rather tough. A transient hemiparesis was observed in one of Immermann's cases to which I have referred. In that case also no lesion was discovered in the brain. Possibly in both instances the cause of the nervous symptoms lay in an undetected minute hæmorrhage. In the foregoing case also the large amount of dropsy was unusual, and the kidneys were certainly indurated, but not wasted or fatty. There have been cases where it has been more difficult to decide whether one was dealing with chronic Bright's disease or anæmia simply, and on this ground I have excluded one case which occurred in 1876, of a man, aged fifty, whose symptoms were those of pernicious anæmia, but where the kidneys were more obviously diseased than in the present case.

CASE 4.—Caroline F——, unmarried, cook and housekeeper, was admitted under Dr. Cayley's care on June 2nd, 1879. Beyond an attack of "inflammation of the bowels" at the age of twenty-four, she had enjoyed good health, but for the past two years had been ailing, losing colour, getting thin, and suffering from shortness of breath for the past six months especially. She was considerably emaciated, feeble, and anæmic, but her appetite and digestion were good. Beyond unusual visibility of the cardiac impulse, there do not appear to have been any cardio-vascular signs. The anæmia certainly was most intense. On June 9th the hæmoglobin was estimated at 28 per cent., and the red corpuscles 550,000 per c. mm., or 11 per cent. of the normal. The temperature only rose to 100° and 100·4° on three occasions, being generally normal. There was diarrhœa with occasional vomiting, but neither occurred to a considerable extent; there were no retinal hæmorrhages. Under arseniate of iron she rapidly improved. On August 23rd, the number of red corpuscles was 37·7 per cent., and on September 22nd, the day before her discharge, 2,080,000 per c. mm., or 41·6 per cent. She remained fairly well for more than twelve months—namely, to Christmas, 1880, when her weakness returned. She began to suffer from shortness of breath, palpitation, and occasional vomiting, and was admitted again on March 2nd of this year, having kept her bed for two months. Her skin and mucous membranes are intensely pale, and she complains of great exhaustion, but has a fairly good appetite. The heart's impulse is diffused and thrilling, and a rough systolic murmur is audible at both apex and base, the second sound at the pulmonary cartilage being accentuated. There are also bruits in the carotids and in the jugular, there being further marked pulsation of the jugular vein. Pulse small and compressible; no retinal hæmorrhages. Urine: sp. gr. 1020, acid; free from albumen. The temperature has not risen above 99°, nor the pulse above 100. The case is still under treatment, principally good diet, rest, and arseniate of iron being prescribed. As yet not much progress has been made, for although on admission the red corpuscles numbered only 520,000 per c. mm., or 10·4 per cent. of the normal, and increased nine days later to 620,000, or 12·4 per cent., yet the percentage of hæmoglobin has fallen from 30 to 21. With the increase in the red corpuscles there has been a change in the number of leucocytes, which were to the red as 1 to 52 on admission, and on the 11th 1 to 124. This case must be regarded as one of idiopathic anæmia, although it is lacking in some of the distinctive features, especially the existence of retinal hæmorrhages. The chief point of interest is the improvement which took place during her residence in the hospital eighteen months ago, an improvement which was maintained for upwards of one year. The ultimate prognosis must be considered as uncertain.[2]

CASE 5.—Emil M——, an Italian boy, seven years of age, admitted under Dr. Cayley's care on January 6th, 1880. His father was alive and healthy; and he had one brother also very healthy. The mother had died of puerperal fever after her second confinement. This boy had never been a strong child, and had had scarlet fever four years ago. In the summer of 1879 he began to get very weak and continued in a weak state until Christmas, when he complained of headache, became listless, objected to move about, and did not care to play. At the same time he lost appetite and suffered from a slight cough. He was well nourished, but extremely bloodless, face of a waxy appearance, lips pale. Marked œdema of conjunctivæ. The heart's apex impinged in the normal position, and a soft systolic murmur was there audible. There was also a whirring bruit in the carotid, and a well marked hum in the jugular. There was a slight cough and some scanty moist crepitation at the bases of both lungs, where also resonance was impaired. There were also signs of some ascitic effusion. Urine: sp. gr. 1015, free from albumen. The pulse rate throughout was very rapid, from 140 to 160, and its volume small and compressible. The temperature was irregular, falling from 100·6° on the day of admission to 98·2° the next morning, and then varying between 98·4° and 99·8° until the 12th of January, when it rose to 102·6°, falling to 99·8°, to rise again to 102·6°, after which it oscillated between 100·6° and 100·2°, until his death on the 17th. Restlessness, varied by great drowsiness; frontal headache at times severe, and towards the close cramps in both legs marked the progress of the case, and vomiting occurred on the last two days. There was constipation; never any diarrhœa. There were extensive retinal hæmorrhages and swelling of the optic discs, and on the last day of life he became quite blind. Iron and its arseniate were the remedies employed, and transfusion was entertained but discarded, as the case seemed beyond recovery. At the post-mortem examination the heart was found to be advanced in fatty degeneration, the change being most marked in the left ventricle, the general wall of which was very friable and of a yellow-red colour, whilst the layer of muscular tissue immediately beneath the endocardium—both on the papillary muscles and the parietes—was speckled and streaked by whitish spots and lines. A few opaque patches occurred also in the mitral valve. Both lungs were engorged and purplish in their posterior two-thirds, numerous ecchymotic patches occurring beneath the visceral pleura, and in the substance of each organ; whilst the bronchi contained some blood-stained tenacious mucus. The spleen was pale, its follicles large, prominent, and white. Liver, large, firm; its lobules well-defined, the central part of each lobule appearing as a whitish-yellow ring, giving the organ a curious speckled appearance visible through the capsule. This was due to fatty degeneration. The kidneys were simply bloodless. This was a pure case of idiopathic pernicious anæmia, and is interesting on account of the extreme youth of the patient.

CASE 6.—Elizabeth Y——, aged twenty-one, unmarried, a nurse, admitted under my care on Jan. 20th, 1880. She had had no serious illness, but for some years had had very little colour and had gradually got paler. The catamenia, which commenced between the ages of fifteen and sixteen, became abundant and frequent in August, 1879; and at the same time she became gradually weak, suffered from giddiness, palpitation, and shortness of breath on exertion. She was well nourished, but extremely anæmic, and complained of great weakness and thirst. There was a marked thrill with the impulse of the heart, and a loud, almost grating bruit at the pulmonary cartilage. The apex beat was in the normal position. Temperature 100°; pulse 146. (See Chart 3.) The temperature rose to 102·8° in the evening of the 21st, and, with remission to 101° next morning, was 103·4° the following evening, the pulse still being very rapid, and the patient having sore-throat and headache. The red blood-corpuscles numbered 2,490,000 per c. mm., or 49 per cent. The catamenia, which had been flowing for ten days before admission, continued, passing into profuse hæmorrhage—so much so that in five days the corpuscles fell from 49 to 20 per cent. (Jan. 28th). Dr. Hall Davis was consulted, and, on the failure of plugging to arrest the flow of blood, the long continuance of which was assuming alarming proportions, endeavoured to check it by the injection of perchloride of iron, ergot being given by enemata, as it could not be retained by the mouth. She became drowsy and apathetic; the cardiac bruit increased in intensity; and, in spite of all efforts, continued to lose blood, a very marked rise in temperature being noticed as the anæmia became more and more profound. She died on Feb. 5th,* a petechial eruption appearing about the trunk and limbs shortly before death. There was a large amount of subcutaneous fat, and the dark-red colour of the muscles contrasted with the thin and watery blood. There were extensive subpericardial ecchymoses on the surface of the heart, the muscular substance of which, especially of the left ventricle, was very pale, speckled, and extremely fatty. There were purpuric spots also over the kidneys. The ovaries were rather large and fleshy, and contained cysts; in the right was a rather recent corpus luteum. The uterine mucous membrane was

* Quinine, twenty grains.

---

[2] This patient became rather rapidly worse and died on March 25th.

pale and smooth, a minute sessile polypus, the size of a pin's head, showing no evidence of ulceration, occurring at the entrance of the left Fallopian tube. The idea that this was the cause of the hæmorrhage was quite untenable. Indeed, the case might be interpreted as the development of the hæmorrhagic diathesis in a chlorotic subject. The chlorosis preceded the menorrhagia, which in its turn intensified the anæmia, and the uncontrollable loss of blood thus arising could not be repaired. Transfusion was clearly out of the question until that constant bleeding could be stanched.

As I have already remarked, the field of view has been so widely extended since the time of Addison that one is embarrassed by the attempt to analyse the cases which have been recorded as progressive pernicious anæmia. Some of these clearly belong to the category of Addison's cases, others obviously do not; so that in perusing them one is continually being confused by the assumption that we are speaking of the same things. Undoubtedly it will be a great gain when we can once and for all rid ourselves of the term "idiopathic" in medicine. There must be an underlying cause for every departure from the normal mechanism. But the time has not yet come. So far as I can gather, then, the term "pernicious" has been used in different senses, some simply employing it to serve as the expression of the severity of any case of anæmia, no matter how arising; others stamping it with a specific character, going behind the strict meaning of the word, and implying by it that it deals with a form of anæmia which is wholly peculiar, and only lately known. What wonder, then, at the mystery and obscurity which veil the subject? One by one the criteria attempted to be established between this form of severe anæmia and other forms nearly but not quite as severe, have been or are being broken down; the one that most resists explanation being the intractability of the disease to ordinary therapeutic measures. But there are problems concerned in it which remain to be solved. At present I think we are in a position to take this view, that to a considerable number of cases the term "idiopathic" is inapplicable, there being in other words a sufficiency of causes in operation to establish the anæmic condition, but that its *pernicious* and *progressive* characters are impressed on it by changes of which we know nothing, or nearly nothing. It may be urged that this is but begging the question and removing the idiopathic origin a step nearer. It is hardly so, for I think it justifies us in establishing such a classification as this:—

Anæmia	Symptomatic	Simple.
		Pernicious.
	Idiopathic	Simple.
		Pernicious.

Such a classification would be warranted by our present knowledge, and would differentiate between the two main forms of pernicious anæmia, destined like the simple forms, to be merged again into one, when etiology shall be perfected. "Idiopathic" and "pernicious" are not, then, alternative terms, although a large number of the latter fall under the former class. Out of the 110 cases whose records I have studied, in forty no cause has been attributed, or the record is silent on it; in others the alleged cause is too remote and too slight to have influenced the case at all, but the chief causes which are sufficient and which stood in sufficiently close relation to be regarded as causes were these:—1. Bad living and food in eleven cases, often conjoined with other more immediate influences, as pregnancy and lactation, or gastro-intestinal disturbance; the latter no doubt produced by these bad circumstances. It has been pointed out that the great prevalence of pernicious anæmia in the Swiss cantons, especially in Zurich, is related to the impoverished condition of the peasant folk, amongst whom the cases of the disease are most frequently met with. They live chiefly on potatoes and coffee, a diet not conducive to healthy blood, formation, and sufficient of itself to lead to anæmia, even of this fatal kind, and the supervention of further debilitating influences nearly sufficiently explains the occurrence of such anæmia. It is objected to this, that the same causes are in operation elsewhere without such results, and that an endemic influence is quite a gratuitous hypothesis. That when removed from such influences other subjects recover from their anæmia; not so these, who become progressively worse, uninfluenced by treatment. Looking, however, to analogies from other diseases, and our knowledge of etiology in general, it seems hardly warrantable to prolong a vain search after other causes in the face of such self-evident ones as these; and remarkable as is the fact of this limitation of fatal anæmia to small districts, it is not more remarkable than other facts concerning the geographical distribution of many diseases. 2. An even more potent cause, often associated with the first, is *pregnancy*, especially if the woman be submitted to the exhausting influences of rapidly repeated pregnancies. It was the starting-point of the pernicious anæmia in 20, or rather less than one-fifth, of the 110 cases. Abortion is liable to occur, and its occurrence is generally followed by the death of the parent, although there may not have been any great loss of blood. Sometimes repeated vomiting in pregnancy is followed by anæmia of this extreme kind, which may also supervene upon flooding in labour, prolonged lactation—causes often enough of a simple symptomatic anæmia, fortunately seldom of a pernicious. Menorrhagia is a sequel as well as a cause of anæmia, and one of the cases appears to have commenced at the menopause. 3. *Digestive* and *intestinal* disorders appear to be at the foundation of several cases, and this, independently of bad diet in many, but clearly the records show that dyspeptic symptoms, vomiting, and diarrhœa have troubled the patient at the very outset, before the subjective or objective symptoms of anæmia have developed. Frequently, as we have seen, the same gastro-intestinal symptoms appear during the course of a pernicious anæmia. Dysentery and typhoid fever may be followed by an anæmia which becomes pernicious in degree. 4. Malarial influences have been supposed to play a great share in determining the pernicious character, but it is singular in how few cases a distinct history of previous intermittent fever has been obtained, and many of the patients have not lived in malarial districts. Then there are cases in which the profound blood change has been set on foot by direct nervous shock, by fright, grief, or worry. In a word, the *known* etiological factors of pernicious anæmia are those of simple anæmia. The symptoms of pernicious anæmia are those of simple anæmia aggravated and intensified. The effects of pernicious anæmia are the same as those of simple anæmia, carried to an extreme degree.

If we turn now to those cases where it is impossible to detect with our present knowledge any etiological factors for the anæmic condition—if we deal, that is, with purely idiopathic cases,—we are bound to seek for causes within the organism itself. That search has been only in part successful. As in all cases of anæmia a cause must be sought in one of two directions, that of diminished activity of blood formation, or excess of activity in blood destruction, attention must be paid to each of these points, especially as regards the blood and the blood-forming organs. Of these I shall shortly speak.

The degree to which the hæmoglobin may be diminished has not been much estimated; but Quinquad found that when it reached 26·5 grms. per 1000 cc. of blood—i.e., about one-fifth of the normal quantity,—the case was invariably fatal, and then there is also a diminution in the solids of the serum. In this, as in other forms of anæmia, it has not been shown that there is any relation between the number of corpuscles and their richness in hæmoglobin. One of the cases I have related, it will be remembered, gave a diminution of corpuscles to 530,000 per c. mm., or 10·6 per cent., whilst the colour test for hæmoglobin showed that there was 30 per cent. of that substance. The case is proportionately grave, therefore, when the corpuscles and hæmoglobin are *pari passu* diminished. Quincke is inclined to doubt the value of observations on the amount of colouring matter in this disease, believing that some of it is in an inactive state, occurring as the detritus of the corpuscles. Most of his numerations are remarkably low—e.g., in four cases, $\frac{1}{8}$, $\frac{1}{10}$, $\frac{1}{15}$, and $\frac{1}{35}$ of the normal, the last being a case in which recovery took place, and the temperature chart of which is before you (No. 2). Many observers have met with variations in the size and form of the red corpuscles. Such variations include corpuscles larger than natural; others much smaller and spherical—the so-called microcytes, at first regarded by Eichorst as pathognomonic of pernicious anæmia, but since abundantly disproved, for they may be absent, and certainly occur in simple anæmia; and numerous smaller and misshapen bodies. Quincke laid especial stress upon alterations in shape; and I place before you a copy of his drawing which gives an illustration of the multiplicity of shapes and variations in size which the corpuscles may be found to undergo. Similar changes are described and figured by Dr. Finny, and have been observed in other cases, of which I may mention one, for the notes of which I am indebted to Dr. Pye-Smith. Irregular massing of corpuscles, rather than a tendency to form rouleaux; rapid appearance of crenation; pear-shaped, biscuit-shaped, globular forms; an excentric position of the depression on the surface of the globule, or the readiness with which the colouring matter accumulates in the corpuscle at one part, so as to give the corpuscle a nucleated appearance, are amongst the alterations observed after the blood is shed. They indicate a greater proneness to form-changes than in healthy blood, perhaps determined as much by altered quality of serum as by any integral change in the corpuscles themselves. At the same time the predominance of small forms and what appear to be broken fragments of corpuscular matter point either to an accumulation in the blood of imperfectly formed elements allied to M. Hayem's hæmoblasts, or, on the other hand, to evidences of the disintegration of the corpuscles.

Since neither the spleen nor lymphatic tissues show any evidence of change, the discovery of the blood-forming function of the bone-marrow by Neumann has naturally led to its examination in cases of pernicious anæmia, but with results both positive and negative. Dr. William Pepper of Philadelphia, in 1875, was the first to offer this explanation of this obscure disease, and described definite changes, chiefly of small granular cells in the marrow of the radius and sternum in one case. Cohnheim in the following year also described a condition of hyperplasia of the bone-marrow, fat being almost entirely absent, and the marrow of a red colour. Besides ordinary marrow and lymphoid cells he found a large mass of small red corpuscles, a few fully formed ones, and an abundance of nucleated red corpuscles of various sizes, some of which were found in the blood itself. The next most important contribution is that by a member of this College—Dr. Osler, of Montreal—who in two cases, one in conjunction with Dr. Gardner and the other with Dr. Bell, made a very thorough examination not only of the blood but of many of the bones of the skeleton. The marrow was of a violet-red colour and almost destitute of fat, containing besides the ordinary elements a large number of nucleated red corpuscles, similar to those described by Neumann as transitional forms between lymphoid cells and red corpuscles. Dr. Osler,[3] in examining the marrow of the long bones in fourteen cases of chronic disease, found evidences of a similar hyperplasia in only one case. Others have confirmed these observations; and others, again, have not been able to show any such changes in the marrow, whilst Eisenlohr,[4] finding that the alterations in the blood and marrow, similar to those described, were met with in a case of cancer of the stomach as well as in one of pernicious anæmia, is inclined to regard these conditions as dependent on the cachectic state rather than the cause of it, and a similar opinion has been expressed by others.

The question, however, cannot yet be entirely disposed of, and there is no *primâ facie* reason against a myelogenic anæmia sometimes occurring. If it do occur, then it points to defect in the normal evolution of the corpuscles, and we have the strange concurrence of appropriation of material by a blood-forming organ and development of the corpuscles up to a certain point, but no further. Meanwhile research is also being prosecuted in the other directions—viz., increased destruction of blood elements, Quincke finding large quantities of iron deposited in the liver, kidneys, and pancreas, in one or two cases of this disease; but his observations, as well as the solitary observation of Dr. Finny as to excess of iron in the urine, require further confirmation before being finally accepted. Further, I may remark that, in two cases of Quincke's, the total quantity of blood was estimated by a simple process of calculation of the corpuscular richness before and after transfusion, and it was found in these cases to have fallen to 5 per cent. and 4·34 per cent. of the body weight, the normal being 8 per cent.

In conclusion, one cannot fail to be struck by the broad resemblance in the midst of difference that exists between the course of a fatal idiopathic anæmia and leukhæmia and Hodgkin's disease (or pseudo-leukhæmia, as it is called)—a resemblance due to the factor common to all of them: the diminution of the oxygen-carriers of the blood. In leukhæmia there may be both an increased production of white corpuscles and an incomplete conversion of them into the red. In Hodgkin's disease, or pseudo-leukhæmia, there may or may not be any leucocytosis, but there is certainly deficient formation of red corpuscles; and in idiopathic anæmia there must be either such deficient formation or an excessive consumption of these same elements, so that there is no sharp line of demarcation between the two. Similarly in chlorosis we have a disease, the characteristic of which appears to be an imperfect evolution of the blood, and except in a few instances it does not seem possible to distinguish chlorosis from idiopathic anæmia. I must not, however, be contented with this mere assertion, and propose, therefore, to speak of chlorosis in its relation to idiopathic anæmia at the commencement of my next lecture, when I hope also to enter more fully into the effects of the anæmic state.

ON GASTROSTOMY.

WITH TWO SUCCESSFUL CASES, ONE FOR CICATRICIAL AND THE OTHER FOR CANCEROUS STRICTURE.[1]

By THOMAS BRYANT,

MEMBER OF THE COUNCIL AND FELLOW OF THE ROYAL COLLEGE OF SURGEONS, SURGEON TO AND LECTURER ON SURGERY AT GUY'S HOSPITAL.

THE case to which I draw attention is one upon which I performed the operation of gastrostomy on August 3rd, 1880, for cicatricial stricture of the œsophagus. The patient was a girl, aged twenty-two, named Lydia C——, admitted into Guy's Hospital under my care on July 15th, 1880. It seemed from her history that she had been healthy and steady up to January, when from some domestic trouble she, with suicidal intentions, took half a wineglassful of sulphuric acid. Medical advice was at once obtained, and an emetic was said to have been given, and after the lapse of a certain number of weeks the soreness of her mouth and pharynx disappeared. Difficulty of deglutition, however, was soon experienced, and steadily became worse, so that for some weeks before admission she had lived entirely on liquids, and these were swallowed with great difficulty. Indeed, it took her almost an hour to swallow half a pint of milk.

When the patient came under my observation she was pale, emaciated, and feeble, and although I made many attempts to pass a bougie or catheter down the œsophagus I never succeeded, the instrument invariably being stopped at the upper orifice of the œsophagus, behind the cricoid cartilage. Under these circumstances I determined to open the stomach, and operated on August 3rd. The operation was performed with the patient under the influence of the anæsthetic mixture and under the carbolic spray. It was commenced by an incision three inches long, running obliquely below the margins of the left ribs, and the skin and muscles were consecutively divided down to the peritoneum; all bleeding vessels were twisted, and capillary oozing arrested by a hot sponge. The peritoneum was then divided, and the left lobe of the liver, which became visible, was pressed upwards. The stomach was then readily found, and brought well forward to the surface of the wound. Great care was observed to keep the parts well sponged, to guard against anything passing into the peritoneal cavity. Two loops of fine carbolised silk were then introduced through the peritoneal covering of the stomach, about a third of an inch apart, and with these and a pair of tenaculum-pointed forceps the stomach was kept *in situ*. The ends of the loops were left long. The stomach was next carefully fastened by a series of interrupted sutures to the margins of the skin around. The sutures merely included on the one hand the peritoneal covering of the stomach, and on the other neither included the parietal peritoneum nor the divided muscles, but the skin alone. The stomach at this stage of the operation was not opened. During the next five days the patient was fed by nutrient enemata every three or four hours, and enough morphia was administered subcutaneously to give rest. The wound was covered with lint saturated with terebene and oil. No sickness, elevation of temperature, pain, or other trouble followed the operation, and on the sixth day the stomach was opened. The opening made was very small, not more than the eighth of an inch long. It was made by elevating the stomach by means of the two loops which had been introduced through the peritoneal covering of the stomach at the first stage of the operation where the ends had been left long, and cutting with a narrow tenotomy knife from loop to loop. The loops were then removed. The patient did not feel this part of the operation.

---

[3] Gardner and Osler, Case of Progressive Pernicious Anæmia. Montreal, 1877.

[4] Deutsche Arch. f. Klin. Med., xx., 1880.

[1] Read at the Harveian Society, March 17th, 1881.

An india-rubber tube, with its end cut obliquely, was then introduced into the stomach through the small orifice, which it dilated, and some milk was poured into the stomach through a funnel. After this the patient was fed regularly through the artificial gastric orifice, and the case went on in all ways well. The girl in three months had gained 19 lb., or about a pound and a half a week. For some weeks after the operation she was fed upon minced meat and pancreas made into a pulp, and this thick food was readily passed into the stomach by means of a simple apparatus, which may be described as a small valveless Higginson's syringe, with one tube fitted with a funnel for the introduction of the food, and the other cut obliquely to facilitate its introduction into the stomach through the artificial orifice, the patient with her finger and thumb so nipping alternately the respective ends of the tube when the syringe is compressed as to prevent regurgitation.

I should say that this apparatus, which was made by my dresser, Mr. Studer, enables a patient to be fed on thick instead of liquid food. The patient has been able to take fluids by the mouth since the operation, and to swallow small crumbs of bread or sponge-cake, but I have not yet been able to pass any tube into or through the stricture. It is to be noticed that there has not been under any circumstances the smallest escape of the stomach's contents through the artificial opening, and this is demonstrated by the healthy aspect of the orifice and of the parts around. This happy result is doubtless due to the smallness of the orifice which I made, and the elasticity of the walls of the stomach; the artificial opening yielding readily to the introduction of the obliquely cut end of the tube, and closing on its removal by its own elasticity.

The advantages of this condition are obvious: the patient is saved the annoyance necessarily appertaining to the escape of the stomach's contents, as well as the local distress and irritation which the escape of gastric juice always causes. She is, moreover, able to take her meals standing or sitting with little trouble and without inconvenience; indeed, with all truth, it may be said that the patient is now, eight months after the operation, in the enjoyment of excellent health, and with the exception of the loss of some, though not all, of the pleasures of the table, there is nothing in her condition either to shorten life or to render it less valuable.

Remarks.—The operation of gastrostomy is applicable to two chief classes of cases—to those of stricture or obstruction of the œsophagus from cancer, and to those of cicatricial stricture. In the former class the operation is not curative, but palliative; it is undertaken mainly with the view of prolonging life, and secondarily as a means of diminishing the agonies of a death from starvation. In the latter class it is undertaken with the view of saving life. In the former class consequently the results of past experience are neither over-brilliant nor encouraging, since out of thirty cases tabulated by M. Verneuil up to 1879 twenty-two sank within the first week, and two alone survived the operation a month. One, however, was then living five months after the operation. It is to be remembered, however, that up to the present time the operation has almost always been postponed too long—that is, it has been only entertained when the patient was literally at death's door, and undertaken with the view of palliating the tortures of a death from starvation, and under these circumstances it is not to be expected that grand successes should be recorded.

Were the operation undertaken earlier better results would be obtained; and I have the records of an unpublished case of my own before me, which shall be appended to this paper, in which the patient survived the operation more than eight weeks; and my colleague, Mr. Howse, tells me that four cases upon which he has operated lived from five weeks to seven months. If, however, the operation were undertaken, as I hold it should be, as soon as the diagnosis of the case is made, and as soon as the obstruction is marked enough to prevent the deglutition of solid food, better results would be obtained; for by such a practice the patient would be in a better condition to undergo the ordeal, the stomach would be less atrophied, and consequently a better organ to deal with; the miseries of hunger would be guarded against, for they would be anticipated; and above all, the progress of the cancerous disease in the œsophagus would be rendered less rapid, and its disintegrating changes would be postponed, in the same way as surgeons now know by the operation of colotomy cancerous stricture of the rectum is relieved, and the changes in the cancerous growth are retarded if not prevented.

In the second class of cases where the operation had been undertaken for cicatricial stricture better results are to be told, for Verneuil's case lived seventeen months and died of some unknown disease. Trendlenberg's case was living three years after the operation. My colleague, Mr. Howse, had a case two years ago which still lives, and the present case promises to demonstrate still better the value of the operation, for the patient is not troubled, as all the others have been, by the escape of the contents of the stomach from the artificial orifice and the consequent local soreness and irritation which such an escape entails. And this leads me to make a few remarks on the operation itself. The incision I made, and believe to be the best, is an oblique one about three inches long and half an inch below the borders of the left ribs. The tissues should be divided carefully down to the peritoneum, and everything like bleeding should be stopped before the peritoneum is opened. The stomach as soon as caught should be brought well forward into the wound and held with a pair of tenaculum-pointed forceps; two loops of carbolised silk should then be introduced, about half an inch apart, through the peritoneal covering of the stomach and its subserous tissue, to indicate the spot at which, on some future day, the artificial opening is to be made. The stomach is then to be carefully stitched to both edges of the skin wound by a number of fine stitches passed through its serous covering alone, in the same way as Nélaton suggested in the operation of enterotomy for abdominal obstruction. There does not seem to be any necessity to include in these stomach sutures the divided parietal layer of peritoneum, the edges of which naturally fall against the wall of the stomach, which is well brought forward. The patient is then to be left alone, and fed by nutrient enemata, to allow the stomach rest and time to unite with the abdominal wound, and after the lapse of from three to five or six days, according to the necessities of the case, the stomach should be opened. In this case I completed the operation of opening the stomach on the sixth day. The full credit of this suggestion is due to my colleague, Mr. Howse, and I have adopted the practice in two cases after witnessing its benefit in several instances. I believe this method of operating has great advantages and tends to make the operation safer. The opening into the stomach should be very small; in the present instance it was no larger than the width of a tenotomy knife, and yet experience has proved that such an opening is elastic enough to allow of the easy introduction of a tube equal to three-eighths of an inch in diameter, and to prevent the regurgitation of even a drop of liquid from the stomach. The stomach having been opened the patient was fed at once, for the first few days with milk, eggs, and beef-tea, but later with beef and pancreas minced and cooked by a simmering process till the whole was almost liquefied. At first a tube and funnel were used, but later on the thick food was more readily introduced by a simple apparatus [shown and described]. The girl can now take liquids by the mouth, and a little solid. Still no tube can be passed or opening formed into which any probe can be passed. Under such circumstances there is but little prospect of her doing without artificial feeding.

By way of conclusion let me urge upon my medical friends to suggest a resort to gastrostomy in cancerous obstruction of the œsophagus so soon as the diagnosis is made, and there is practical difficuty in the deglutition of solid food, for by an early operation many more lives would be prolonged, and much misery saved. The progress of the disease, moreover, would be greatly retarded. Whilst in cicatricial stricture the operation should be resorted to only when all hope of the stricture being dilated has vanished, and there is no other alternative.

Cancer of Œsophagus; gastrostomy; death two months after operation from extension of the disease to the trachea, lungs, liver, and mediastinal glands.

(Reported by Mr. HIND.)

J. B——, aged sixty-one, a labourer, was admitted into Stephen ward on Feb. 25th, 1880, under Dr. Wilks' care. Patient has enjoyed good health; never drank much. Has had gonorrhœa, but not syphilis. Ten months before patient first noticed difficulty in swallowing solid food. It appeared to stick in the œsophagus on about a line with the upper end of the sternum. He subsequently was unable to swallow his food, and vomited it immediately. His appetite has remained good. He has not suffered much pain. On admission he has apparently lost much flesh; his skin is hot and dry. He has a circumscribed fluctuating tumour situated over the inner half of left clavicle, not infiltrating the skin; it is not painful, and the patient had never noticed it. A few small glands are enlarged at the lower part of the posterior triangle of the neck. About a fortnight ago an abscess formed on the dorsum of the left foot, which is very red and inflamed. Tongue moist, furred, and white. Teeth not good, only two left in the upper jaw. Bowels open.

Feb. 26th.—House-physician passed a bougie down the œsophagus, but it did not pass lower than on a level with the upper part of the sternum. To take one ounce of brandy three times a day, with eggs.—March 2nd: The tumour is 3″ long by 1½″ deep; feels elastic and soft, and at anterior end is soft and fluctuating. Deficient entry of air all over the chest; chest expands tolerably; no dulness; no signs of invasion of thorax by growth; breathing hoarse all over chest. The house-physician passed a large, then a small bougie, both to about 4½″ below epiglottis, corresponding to a point immediately above the sternum.—6th: Fluctuation of swelling; opened by Mr. Bryant, and four ounces of pus came away.—10th: One ounce of brandy to two ounces of milk as an enema.—11th: Mr. Bryant performed first part of operation of gastrostomy, as described in the last case. The wound healed kindly without any peritoneal or other complications.—16th: Operation completed; opening into the stomach a small one.—17th: Temperature normal; fed every two hours with four ounces of milk and an egg, and half an ounce of brandy occasionally.—18th: Injection every four hours; temperature normal; bowels open; tongue fairly clean.—19th: Abscess on foot opened.—22nd: Temperature normal; fed six times a day, two of which consist of milk and eggs, the remainder of meat; about four or five ounces of brandy; weighed 98 lb.—23rd: Leg put on back splint.—25th: Up in a chair in ward.—27th: Fed four times a day.—April 21st: Weighed 103 lb.—May 5th: Cough troublesome; weaker.—10th: Died.

Necropsy by Dr. Hilton Fagge.—Body much emaciated. A slight sore on one instep, and in the abdominal wall was a fistula to the left of the umbilicus from the operation of gastrostomy. The opening was in the centre of a small amount of scar tissue. It was the size of a No. 10 catheter, and above—that is, the upper margin had upon it an overhanging lip, which looked more like mucous membrane than skin or scar. The cranial bones were normal; no thickening. Dura mater and sinuses, arachnoid and pia mater, were normal. Arteries of head very atheromatous at base. The brain weighed 50 oz. In the head of the outer nucleus of lenticular ganglion upon the right side there was a small-sized cyst of an old apoplexy; its colour was brownish, and its lining membrane smooth, and in its walls were some small vessels. The smaller vessels in the interior of the brain did not look so very thick.—Spine: The spinal vertebræ had various nodosities upon their anterior margins at the line of junction with the intervertebral substances in the lumbar and dorsal regions.—Respiratory organs: Recent lymph over hinder part of left pleura. Both had in various parts, particularly over the hinder part of the lower lobe and in the outer part of the upper lobe, a considerable infection of the lymphatics with cancer. They stood out on the surface as interlacing lines of milk white or yellow colour, forming a rectangular latticework. There were, in addition, in some parts, flat plates of growth spreading in the pleura from these. The lungs felt very solid towards the root. On section they were seamed in various parts by thin lines of cancerously infiltrated septa. These had a head in appearance in various parts, and in the centre of the lung this condition was surrounded by a granular pneumonic lung, which it was difficult to say was not pneumonia. It may have been pneumonia mixed with growth. The heart weighed eight ounces and a half, and was quite healthy. The œsophagus was tightly strictured opposite the second ring of the trachea. There was very little thickening of its coats, but on slitting up the tube there was a jagged white growth in the mucous membrane, without any well-defined margin, and, in addition, a superficial ulcer in the mucous membrane, which ran up vertically in the covering of the thyroid and cricoid cartilage to the left side for more than an inch. The floor of this ulcer presented no cancerous attributes, but the edge of the ulcer was distinctly raised and everted with a soft fleshy growth. The trachea was not perforated, but its wall was extensively implicated. On looking at the mucous surface of the trachea the whole of it, down to the bifurcation, looked mottled and thick, and granular-looking tubercles of growth studding it all down, and from these parts the disease had invaded the external parts. The thyroid body was extensively infiltrated with a similar growth. The glands were affected, but they were not much enlarged. The actual stricture of the œsophagus was not more than half an inch in length. Above and below the parts were normal.—The liver contained three or four small circular, firm, cancerous nodules; in other respects the liver was healthy.—The intestine was in a very interesting condition. Throughout the whole length of the small intestines, but chiefly in the lower part, were ulcers which had rather thick edges, which tended to run round the bowel, and which exposed clearly in the floor the muscular fibres of the bowel. One of these had gone deeper, and by a second ulceration in the already ulcerated surface had all but perforated by a transverse slit, two-thirds of an inch long. The ulcers externally had a puckered aspect, but there was no material narrowing of the bowel, and one at least had very minute white grain-like bodies (? tubercles) in the subperitoneal tissue. I think it was an early tubercular affection of the lymphatics in the floor of a chronic ulcer. Near the cæcal valve the ulcers became more irregular and more superficial—not like any particular ulcer—and similar small superficial circular and oval ulcers ran down in the large intestine for some distance. But there was one additional peculiarity in the large bowel. The mucous membrane was smoother than usual, and sanded over with multitudes of small rough-looking grains, distinctly projecting from the surface. I hesitated to pronounce an opinion on its nature. They were too prominent, and abruptly so, for solitary glands. No lardaceous disease of liver or intestine.—Spleen: The capsule was thick. The suprarenal capsules were healthy.—The kidneys weighed eight and a half ounces. One kidney was very good. The other contained many cysts of small size, but its cortical structure was good.—Most of the joints showed osteo-arthritic changes. The toes were nodular at their edges. The knees had a large part of their surface from centre outwards devoid of cartilage, and eburnated; while at the margin of the cartilage there came a nodose edge of bone. The elbows were in a similar state. The synovial membrane in knees could hardly be said to be vascular. The shoulders were also affected, the left bicipital groove being markedly prominent from new matter under the muscular attachment of outer lip.—With regard to the ulceration of the intestine, I was in doubt as to its nature. The ulcer in some parts certainly involved part of Peyer's patches, and further they were well-defined, clean-looking ulcers, exposing the muscular coat without any granulations—in this resembling typhoid ulcers which had sloughed out, and not tubercular ulcers. On the other hand, the peritoneal aspect was in no other places in favour of tubercle. The stomach at the seat of operation was firmly united to the skin. No signs of peritonitis were present.

A CASE OF CYSTICERCUS CELLULOSÆ IN THE VENTRICLES OF THE BRAIN; SUDDEN DEATH.

By FREDERIC FLINT, M.D.

A boy in his seventeenth year, a pupil in a large boarding-school at Scarborough, apparently in good health, played on Thursday, Feb. 24th, at a well-contested game of football. On Friday at 10 A.M. he was no more. He took an active part in the game on Thursday, and thoroughly enjoyed it; in the evening he complained of headache, and went to bed early; he vomited once or twice during the night, but did not disturb another boy who slept in a separate bed in the same room. On Friday morning he did not appear at the breakfast-table, and the head-master of the school went immediately to see him. He then complained of his head aching severely, and of having vomited, and the terrible scene, which came to so speedy an end, began. The poor boy made several heart-rending, piercing cries, clapped his hands to the *back* of his head, and cried for pain there; his eyes became fixed as if he were going into an epileptic fit; he began to pick and pull rapidly at his eyes and mouth, then to scratch his skin violently as if he would tear his flesh off, especially about the inner part of the thighs and the pudenda, so that strong force was needed to prevent him doing himself injury. He then buried his head and body under the bedclothes, and in agony tried to bore his head into the bed. He several times drew his knees up to his chest, and violently thrust his limbs out again; there then followed severe shudderings of the whole frame, which, to use the expression of one who most patiently and carefully attended him, "seemed to make all the bones in his body shake together." After a piercing shriek, the case at this stage mercifully passed into coma, with stertorous breathing. At the time of my arrival his face was of a bluish, epileptical colour, the pupils widely dilated, the respiration gasping and at prolonged and lengthening intervals, and the pulse full and strong. While I was feeling the pulse and meditating on the case, in a few seconds it became flickering. I injected ether into the arm, but it had no effect on the pulse, and within two or three minutes of my arrival life vanished away. The whole duration of the seizure was about one hour. I ascertained that there was twitching of the small muscles of the face in the early stage, but it was not very marked; tears poured copiously down the cheeks during the greater part of the time.

On making closer inquiries into the previous history of the deceased, I was informed that he had been at the school for about five years, that he had always taken an active part in the school games, that he had been considered clever and of more than average mental ability, and that he had been of a very generous character, and a favourite with his companions. During the time he had been at school his health had been generally good, but during the latter part of the Christmas term, and since his return after the vacation, he had shown signs of being fagged by his work, and had complained of headache after much study and violent exertion, as after playing at football. During the holidays in endeavouring by skating backwards to pass under a bridge, which could be done only by stooping, he came into collision with the bridge and hurt his spine. This was supposed to account for the headache and complaints which he made after playing at football on his return to school, and he was advised by his associates to discontinue playing for a while. It was not, however, considered needful to take any medical advice about it. The boys also noticed that he had lately been somewhat irritable, and not disposed to give them much help on various occasions as he had previously done. I could not find out that he had ever complained of giddiness or had attacks of vomiting. I was told that about Easter (1880) he had had very severe neuralgia, which affected not only the face but the back of the head, and severely so; the facial neuralgia was relieved by the extraction of carious teeth, but the pain in the back of the head continued for some time, and only gradually subsided. Nitrous oxide gas was administered for the extraction.

As the real cause of death was unknown, apoplexy being so very unusual at such an age, it was considered necessary in the interests of all parties that there should be an inquest, and in this case an inquest proved helpful to the cause of science, for no one, I think, would have ventured to ascribe the death to a cysticercus, especially after he had heard of the skating accident.

An inquest being ordered I made a post-mortem examination of the brain the same evening. I found the coverings of the brain and the venous sinuses gorged with blood; the pia mater was intensely congested, and on cutting into the brain immediately beneath it there were numerous minute spots of hæmorrhage. On opening the left lateral ventricle I noticed it was distended with fluid, but I did not observe anything of special importance. I then opened the right lateral ventricle, and began to feel puzzled as to the cause of such a rapid and intense congestion of the brain. On searching the left ventricle more carefully I discovered what appeared to be a piece of elongated jelly. Wondering what it could be I put it into a glass of water, when it assumed a globular form, and I saw at once that I had secured a prize. I put it on one side for further examination, and searched the third ventricle and the passage to the fourth, but I could discover nothing more. As I was unaided, the time late, and the light only that of a candle, I did not venture to open the abdomen and intestines. This I afterwards very much regretted; but those who are acquainted with the difficulties in performing a post-mortem in a private house, and under the circumstances in which I was placed, will not be severe in blaming me. On examining the cyst I observed that in water it was of the size of a moderate-sized cherry, that it was translucent, and that there could be seen in the interior an opaque body. When placed on a saucer it looked very like a miniature jelly-fish of a light-brown colour, rather larger than a shilling, and in the centre of it there was a yellowish-looking spot, at which there appeared under a magnifying lens, to be some projecting hooklets. At the inquest I gave it as my opinion that the cyst which I exhibited was a cysticercus cellulosæ, and that it was the cause of death. It would be interesting to decide the exact position which the cyst occupied in the brain. I found it in the left lateral ventricle. I did not observe it at first sight, but after opening the right lateral ventricle on searching again in the left I discovered it, and it was then certainly not attached to any part. I think that it must have been about, and possibly engaged in, the foramen of Monro, and that in pressing on the corpus callosum and septum lucidum, to open up the right ventricle, the cyst was dislodged, and pushed into the position where I afterwards found it.

In Ziemssen's Cyclopædia there is reported a case which is very similar to mine. A boy, strong and hearty, had suffered from frequent headaches the year before his death. The headaches came on after violent bodily exertion, and were sometimes accompanied with vomiting, but were never so severe as to require medical attendance. One evening he had a headache, but he ate a hearty meal, and went to sleep. After a few hours he awoke with vomiting, delirium, and great restlessness. His speech was inarticulate; complete loss of consciousness and death soon followed. A cysticercus cellulosæ was found lying free in the aditus ad infundibulum. There were no teniæ in the intestine.

In the account given by Heller of the development of the cysticerci, the head of the worm is described as being downwards in the cyst, and it is stated that in but few cases does the tapeworm head escape externally while in its measly condition. How it could do so is not described.

As the case appeared to be a very interesting one, and as when I opened the cyst the worm appeared of a large size, I determined, instead of further dissecting the specimen myself, to send it to an expert; and as we have in the profession a man of European and world-wide reputation in such matters, I sent it to Dr. Spencer Cobbold, feeling sure that he would make it more interesting and instructive to the profession and the scientific world than I could do.

Dr. Cobbold very carefully examined the worm, and kindly made me a drawing of the head, and sent me a very interesting account of his examination. He stated that in his opinion the parasite was a cysticercus telæ cellulosæ hominis, and "that it is particularly worthy of remark that not only is this bladder-worm of most unusual size, but it is likewise of monstrous character. In place of four it is furnished with six cephalic suckers." When he examined the worm without a magnifying lens he expected it would prove to be an example of the cysticercus tenuicollis. "For," he writes, "it is altogether beyond my experience to have met with any pork-measle of the size of this human specimen." After examining the hooks, of which four or five still remained attached, with the quarter-inch objective he satisfied himself "that the hooks corresponded more closely with those of the ordinary pork-measle than with the hooks of the slender-necked hydatid. . . . . When fully unrolled, and the head everted, the specimen measured precisely two inches in length." Dr. Cobbold has already drawn the attention of the profession to this case in THE LANCET (March 12th), and will show the specimen at the Quekett Club meeting. In a subsequent note Dr. Cobbold states that the appearance of hooklets protruding through the cyst wall was deceptive, and that the head was still concealed in the receptacle when he examined the specimen.

A question of great interest now presents itself. How did this embryo find its way to the brain? As I understand it, such a case could not arise *directly* from swallowing a pork-measle; that as the pork-measle arises from the introduction to the pig's stomach of a mature egg or an egg-filled segment of the tænia solium, so the bladder-worm in man arises from the introduction to man's stomach of a mature egg of the tænia solium either from without, with food or drink, or from within by vomiting from the fully developed segments of a tapeworm in the intestine—i.e., by self-infection. No doubt this case is defective, as the intestines were not examined; I have, however, made careful inquiries, and I cannot hear that the youth ever made any complaint of having passed anything unusual by the bowel, and if the worm had been fully developed in his intestine there can be little doubt that he would have passed some segments, and that they would have attracted his attention. Heller, in Ziemssen's Cyclopædia, states that of von Gräfe's collection of eighty cases of cysticerci in the eye, only five or six patients had been previously affected with tapeworm. It would therefore appear that the embryos usually find access to the body in the food or drink. It would be practically useful to the profession and to the public if such an authority as Dr. S. Cobbold were to take advantage of the interest excited by this case to point out the many ways by which the embryos of the tænia solium may gain admission to the human body.

Scarborough.

THE TREATMENT OF PSORIASIS BY PYROGALLIC ACID.

BY GEORGE THIN, M.D.

THE first notice of the curative effects of pyrogallic acid as an external application in psoriasis is, I believe, to be found in a paper by Jarisch, which is known to me by an extract in Schmidt's Jahrbücher, 1880, No. 3. In this paper a ten per cent. ointment, to be applied twice daily, is recommended, the ointment to be kept in contact with the skin by a bandage in inveterate cases. Jarisch found its use attended with no inconvenience, and states that the discoloration of the skin which it causes is removable by benzole and by dilute acids. The utility of pyrogallic acid in psoriasis has been supported by the testimony of Kaposi, who has warmly recommended it, more especially for cases of psoriasis universalis.

Before trying it on my own patients I became, however, aware through a case reported by Neisser, to which I shall again refer, that its application to a large surface might be attended with danger, and feeling satisfied that it is never justifiable in the treatment of ordinary cases of psoriasis to subject a patient to any risk, however insignificant, I commenced by using it over a very small extent of surface at a time. A slight experience of this treatment was sufficient to satisfy me that we had become possessed of a powerful agent for the treatment of psoriasis, and one that is not attended by the inconveniences that are associated with the use of chrysophanic acid. I accordingly availed myself of a favourable opportunity for testing its action, as compared with that of some of the more commonly used stimulants which are applied to the skin in psoriasis, and now propose to record the results of the experiment.

A young gentleman, aged twenty, consulted me in March, 1880, for a psoriasis of long duration. He intended going abroad for a period of years, and was desirous of ascertaining the best method of keeping his disease in check without resorting to repeated courses of arsenic. He therefore willingly accepted my suggestion of trying the effects of different applications on different patches.

The disease first appeared on his elbows when he was five years old. When he was twelve the knees became affected. In his eighteenth year the disease became more general, patches developing on the legs, abdomen, back, and arms. When I saw him I found the knees and elbows affected with patches, varying in size from that of a shilling to the palm of the hand, on various parts of the body. They were mostly about two inches in diameter and rounded in form, and were well-marked examples of the disease, a slightly bleeding surface being left when the scales were forcibly removed. The other applications with which the pyrogallic acid was to be compared were frictions with soft-soap twice daily, the frictions on a number of selected patches being followed by the application of white precipitate ointment and *huile de Cade* respectively. A complete cure was not obtained by these applications on any one patch, although an apparent attempt at recovery followed all of them. Thus the elbow and knee of one side were treated by the soap frictions and white precipitate ointment, and those of the other side by soap and tar (*huile de Cade*), from March 19th to October 21st, continuously and actively, with great amelioration of the condition of the skin, but without a complete cure. Patches on the abdomen and back were similarly treated for a number of consecutive weeks, again with progressive amelioration, but the progress was so slow that, in deference to the wishes of the patient, the pyrogallic acid ointment was substituted. The pyrogallic acid was first applied to an oval patch on the left leg, which was about four inches long and three inches broad, an ointment composed of one part of the acid to ten of lard spread on lint, being laid on it twice daily. After three days' application the local irritant effects produced were sufficiently severe to induce me to discontinue the remedy for the time being. The treatment of the patch was resumed after some weeks with a weaker ointment, one part of the acid to twenty of lard. In six days the patch looked much better, and within a fortnight it was well.

In order to avoid any possible ill effects from the acid a few patches only were treated at a time. Those on the abdomen were attacked first, and then those on the back, and finally those on the limbs. The treatment was begun in the end of May, and by the end of July all the patches, except one or two on the back, had been cleared, and these soon yielded when they were taken in their turn. Finally, on October 21st, the elbows and knees, which had so long resisted the patient treatment by soft soap, white precipitate ointment, and tar, were attacked by the pyrogallic acid in the same strength of one in twenty, and were speedily cured.

The curative action of pyrogallic acid is due, I believe, simply to its irritant qualities, and to certain properties as an irritant in regard to which we are ignorant. The irritant effects are most conspicuous around the hairs, each hair-follicle being the seat of a small brown patch, which, when it is scratched off, often leaves an abrasion in its place. At one stage of its curative action the mode in which the psoriasis patch enlarges is well illustrated, the dull-brown epidermis which marks the extent of the diseased surface being bounded by a thin red margin. This thread-like border corresponds to the vascular congestion produced in the bloodvessels by the extension of the psoriatic epithelium.

Kaposi has treated patients who were subjects of universal psoriasis by an ointment of pyrogallic acid applied to the whole surface of the body, and remarks in his recent handbook regarding the "alarming appearance of strangury and excretion of olive green to tarry urine, with symptoms of moderate fever and prostration, by many patients whose whole bodies had been repeatedly covered by it." Neisser (in the *Zeitschrift für Klin. Med.*, i., p. 88) recites a case in which a patient died from its effects. The patient, a man afflicted with psoriasis universalis, after a warm bath with soft soap, had an ointment of pyrogallic acid applied to the left side of the body and to the surface of the chest. In two hours he became unwell, and had diarrhœa, and four hours later rigors, collapse, high temperature, and tremor set in. After a remission there was in forty hours a repetition of the attack, and he died comatose. There was anuria for the last twelve to eighteen hours. During the sixty hours of illness only 1600 cubic centimetres were secreted, the urine affording a marked example of hæmoglobinuria.

It is clear that the remedy is one to be cautiously handled, but it is equally clear that, used in the strength employed by me in the case which I have related, and used over a small extent of surface at a time, it can be employed not only safely, but conveniently and successfully.

Queen Anne-street, W.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—The Weekly Board have just presented their thirty-second annual report to the governors. During the past year the total number of patients attending the hospital was 12,976. The number of in-patients amounted to 1372; included in this number are 71 infectious cases treated in the fever wing. The average daily number of in-patients was 114. Cost per head £4 7*s.*; cost per bed occupied, £52 5*s.* 9*d.* Average stay in hospital, 33 days. Cost per out-patient, 2*s.* 3*d.* The income from all sources amounted to £7048 3*s.* 7*d.*, and the expenditure to £6924 8*s.* 4*d.*, leaving a balance in hand of £123 15*s.* 3*d.* During the coming summer it is intended, if the funds are forthcoming, to erect a new and detached mortuary and to renovate the sanitary appliances and drainage, as well as to paint and cleanse the interior of the building.

ORCHITIS AS A CONCOMITANT AND SEQUEL OF MEDITERRANEAN FEVER.

BY G. F. DUFFEY, M.D. DUB., F.K.Q.C.P.I.,
PHYSICIAN TO MERCER'S HOSPITAL.

UNDER the above heading Surgeon H. M. Ellis, R.N., Royal Marine Artillery, has recorded in a recent number of THE LANCET (Jan. 22nd, 1881, p. 161) some cases of particular interest. Independent observations of rare forms of disease are always valuable, especially when—as would appear to be the case in the present instance—the observer is unaware that the subject to which he calls attention has been previously studied and described by others.

Having had the honour of serving for five years at Malta with the 1st Battalion of the 24th Regiment, I had exceptional opportunities, of which I endeavoured to avail myself, of studying the forms of fever met with in that island. The special complication or sequela of which Mr. Ellis reports four cases I was, to the best of my belief, the first to give a detailed description of (*Dublin Journal of Medical Science*, Feb. 1872). I ventured to define the affection as "an inflammation of the testicle of a rheumatic character occurring sometimes during, or a short time after, convalescence from fever," and the description given by Mr. Ellis corresponds accurately with the symptoms observed in the cases, eighteen in number, on which my memoir was based.

The fact that several officers of the Army and Naval Medical Departments who have served at Malta have not seen orchitis there after fever, as well as my own experience, would make it appear that this complication has somewhat of an epidemic character; the tunica vaginalis testis, and not, as usual, the aponeurotic and muscular structures of the thighs or back, being, at certain seasons, or under certain unknown conditions, the seat of this "rheumatic" or "neuralgic" complication. Thus Senator (Ziemssen's Cyclopædia, vol. xvi., p. 20), referring to my observation as to the occurrence of orchitis during convalescence from endemic fever in Malta, asserts that it is quite possible that under special climatic conditions other febrile maladies besides scarlet fever, dysentery, and the puerperal state, during or after which polyarthritis is exceptionally prone to occur, may likewise predispose the system to become affected by rheumarthritis; the liability of the patients to become thus affected varying in different epidemics, but being also possibly due—apart from any *genius epidemicus*—to the state of the weather and other circumstances of a local order. Nearly all my cases occurred during the autumn and winter of 1867, while the men were quartered in an unhealthy barrack.

From the considerable experience I have had of the so-called "Maltese" or "Mediterranean" fever, I cannot agree with Mr. Ellis that it is of a remittent type, unless it has changed its character since 1871. In the paper above referred to I gave it as my opinion that there were two main forms of fever endemic in Malta—viz., ephemeral fever or febricula and enteric fever. Nothing that I have learned practically or read on the subject since has made me change the views I then expressed.

Reference to the literature of the subject shows that orchitis is not unknown out of Malta as an occasional complication of typhoid fever. Liebermeister (Ziemssen's Cyclopædia, vol. i., p. 181) states that in men orchitis or epididymitis sometimes supervenes during convalescence from this disease in a proportion, as far as he can judge, of one in 200 cases; and Hanot (*Archives Gén. de Méd.*, Nov. 1878) has reported four cases of orchitis in typhoid fever. In all these instances the right testicle, as is most frequently the case, was affected, and the complication occurred during convalescence from the fever. An army medical officer informed me some years ago that he had had orchitis after fever in India; he also suffered from "rheumatic" pains during his convalescence, but was unable to account for the orchitis until some years subsequently he casually read my paper, which, he said, exactly described his condition at the time.

Fitzwilliam-place, Dublin.

NOTE ON

THE TUNING-FORK IN THE DIAGNOSIS OF DISEASES OF THE EAR.

BY E. CRESSWELL BABER, M.B. LOND.,
SURGEON TO THE BRIGHTON AND SUSSEX THROAT AND EAR DISPENSARY.

IN a very interesting paper on Bone Conduction read by Dr. Knapp at a meeting of the American Otological Society in July last, and in the report of the discussion which followed,[1] I find no mention of a phenomenon bearing on this subject to which my attention was directed more than a year since. I refer to the effect of pressure exerted on the ear on the perception of the tuning-fork. On applying a sounding tuning-fork to the median line of the head, if one meatus be closed (either by inserting the finger into it or by pressing the tragus inwards), the sound of the fork, which on closing the ear lightly is heard loudly in the obstructed ear, if the finger be pressed inwards diminishes in the closed ear with the amount of pressure exerted, until the sound is heard only slightly or not at all louder in the closed than in the unclosed ear. The same takes place with the voice if any note be continuously hummed. In examining persons with normal hearing in this manner, I found that pressure has usually (though not invariably) this effect. In this experiment, the air in the meatus becoming condensed, doubtless forces inwards the membrana tympani and with it the ossicles. In the present incomplete state of our knowledge in regard to bone conduction, as to how far a direct transmission of sound waves through the cranial bones to the labyrinth can take place, or how far bone conduction reaches the labyrinth through the medium of the tympanic apparatus (vide Knapp and others, *loc. cit.*), this phenomenon admits, I think, of two interpretations. 1. It may either be considered due to the inward pressure of the ossicles, causing slight pressure on the labyrinth fluid, by which the functions of the labyrinth are temporarily interfered with; or (2) it may be attributed to the impediment to the vibrations of the ossicles (especially of the stapes), produced by their altered tension. In addition to either of these two causes (or possibly a combination of the two), the fact of the sound waves, which are reflected from the obstruction in the meatus, having to pass through a tympanic apparatus of which the tension is abnormal, probably weakens their effect on the labyrinth. The effect of pressure on the ear may perhaps be analogous to what occurs in those cases (of which several were referred to at the above meeting) in which bone conduction being abolished, it is more or less immediately restored when the tympanum is relieved by inflation or paracentesis. Opinions as to the cause of this phenomenon also varied. Practically it is well to be aware of this effect of pressure on the perception of the tuning-fork if closure of the ear be employed in conjunction with bone conduction as a means of diagnosis.[2] By showing the ease with which altered tension of the ossicles may affect the bone conduction, this observation may assist in explaining some of the exceptional cases met with in practice, in which, although the disease is apparently in the middle ear, the tuning-fork is *not* heard louder in the more affected ear. The whole question of bone conduction, however, needs a thorough reinvestigation, and this is especially required on account of its great practical importance in the diagnosis between middle and internal ear-deafness. The effect of pressure on the perception of the tuning-fork cannot fail to have been noticed before, but it has not, I think, received the attention that it deserves.

Brighton.

---

[1] Some Remarks and Observations on Bone Conduction, Transactions of the American Otological Society, vol. ii., part 4, p. 407.

[2] Hinton (Questions of Aural Surgery, p. 61) cautions against using pressure in occluding the ear, unless it is expressly intended to note the effects of pressure, but does not mention what these effects are.

ARTS EXAMINATIONS.—At the recent preliminary examination for the diploma of Membership of the Royal College of Surgeons, which was conducted as usual by the College of Preceptors at Burlington House, there were 372 candidates, of which number 124 were rejected; the 248 successful candidates can at once commence their professional studies.

STRYCHNIA POISONING DURING THE FIFTH MONTH OF PREGNANCY; RECOVERY.

By ALBERT S. MORTON, M.R.C.S.

At 11 P.M. on Feb. 5th I was hastily summoned to Mrs. H——, who was said to have taken poison. On my arrival, at 11.20 P.M., I observed the following symptoms: Convulsions, risus sardonicus, opisthotonos, redness of face, dilatation of pupil, scratching the body and limbs, free perspiration, bleeding from the mouth, and a bitten tongue. The pulse varied frequently and suddenly, being sometimes normal as to beat, sometimes slower than normal, and at times nearly twice as fast as normal; it varied also as suddenly and remarkably in volume, being at times almost imperceptible, and at others normal or very full.

The convulsions came on five minutes after taking the poison, and continued during the space of two hours. During the first hour they occurred with more or less regularity every four or five minutes. Their strength may be judged from the fact that there was marked opisthotonos, and the tongue was bitten through. During the second hour the convulsions became less frequent, and at the end of the first hour and a half they appeared to have entirely ceased. Half an hour after this (that is at the end of the second hour) the patient asked for a glass of cold water, which I gave to her. On attempting to raise the glass to her mouth she had another severe convulsion, and dashed the glass out of her hand. During the intervals the patient was clear and collected, and then told me she had taken the whole of a large packet of Battle's vermin-killer dissolved in a tumbler of water (probably about three grains of strychnia).

The treatment consisted in the administration of twenty-grain doses of sulphate of zinc dissolved in eight ounces of warm water, and followed by warm water alone, until vomiting occurred. As soon as the sickness ceased the same treatment was pursued until four doses had been administered in all. I was obliged to pour the emetic down with a table-spoon, as the attempt to drink from a tumbler or cup appeared at once to induce a convulsion.

The patient told me during the intervals that her face felt stiff, that she could not swallow well, as her throat was also stiff, that she itched all over, that she had a burning sensation in her throat, and that she would not have taken the poison at all if she had known how painful it would be.

She has not yet had any signs of a miscarriage, and has made a most perfect recovery.

Kennington-park-road, S.E.

CASE OF REMOVAL OF LARGE CYSTOMA OF OVARY, FOLLOWED BY DISAPPEARANCE OF A UTERINE MYOMA.

By LAWSON TAIT, F.R.C.S.

The following case was under the joint care of Mr. Badley and Mr. Messiter of Dudley, with whom I saw the patient in consultation upon July 24th, 1879.

E. D——, single, aged thirty, had severe uterine hæmorrhage and had been noticed to be rapidly increasing in size. A tumour had been discovered by Mr. Badley about a fortnight previous to our consultation. At the time I first saw her we resolved the condition into the presence of two tumours, one cystic and the other, down in the pelvis, solid. On July 31st I performed abdominal section and removed without much difficulty the cystoma. The solid tumour in the pelvis proved to be a myoma in the posterior wall of the uterus, which I could not remove. She recovered from the operation without a bad symptom and went home on Aug. 15th. I saw her on October 10th of the same year, and found the myoma reduced to less than half the size it was at the time of the operation. She was married in December, 1879, and in October, 1880, came to me to know if she was pregnant. There was no difficulty in determining that she was about five months pregnant, and not a trace of the myoma was to be discovered. I am informed by Mr. Messiter that she has recently been confined without any trouble.

This is one of a number of cases from which evidence is accumulating in my hands to show that uterine myoma depends very frequently upon disease of the ovaries, and that removal of the diseased glands cures the myoma. In this case it is remarkable that removal of one ovary was sufficient to secure this desirable end, whilst the other remained sufficiently healthy to enable her to become a mother.

ST. BARTHOLOMEW'S HOSPITAL.

[Ophthalmic Department.]

SYMPATHETIC PTOSIS, PROBABLY FROM DECAYED TEETH.

(Under the care of Mr. Power.)

E. C——, an unmarried woman, aged thirty-three, formerly a domestic servant, was admitted on Dec. 5th, 1880. She was the subject of marked ptosis in both eyes, the ciliary edges of the upper and lower lid being in complete and even apposition on both sides. There was no wrinkling of the skin or other sign of spasm of the outer portions of the orbiculares. She was quite unable to open her eyes, and when pressed to try to accomplish this there was usually marked spasm of the orbicularis oculi, together with contraction of the anterior bellies of the occipito-frontales muscles and horizontal wrinkling of the forehead. On opening the lids with the fingers considerable orbicular spasm ensued; but when this resistance was overcome the condition of the globe was found perfectly natural, its movements being more free, of normal extent, and visual acuity $\frac{20}{20}$. There was no sign of paralysis. The spasm of the orbicularis was most marked when the patient knew she was being observed, and when her attention was directed to it. She, however, complained of a "nipping" sensation coming on at irregular times, and referable to this spasm. This condition had only come on a fortnight before, but she stated that in 1879 the left eyelid was in the same condition, and got well in a short time. Her general health was good; catamenia regular, but painful. It was considered at first that this was a case of hysterical ptosis, and in support of this it was found that the patient did occasionally, when she thought herself unobserved, partially raise her upper lids. She was one day placed under the influence of chloroform, having been previously informed that on coming to herself she would find herself able to open her eyes. While under chloroform her eyes were bandaged. When she recovered consciousness she was assured that she was cured, and the bandages removed. On telling her to open her eyes, she did so widely for a moment, and then relapsed into her old condition. She was ordered shower-baths and tonics, and afterwards valerianate of zinc and assafœtida without any benefit. Her forehead and eyelids were then faradised for ten minutes every morning. This was continued for about ten days, and then abandoned because she refused to submit. The actual (benzene) cautery was applied momentarily to the superciliary eminences without effect. Strips of plaster were attached to her lids and forehead, and covered with collodion. This kept her lids open for a time, but the strapping becoming loose, the ptosis recurred, though to a trifling extent less than previously, for there was now a palpebral fissure of about one-sixteenth of an inch. Thinking the irritation of the stumps of numerous decayed teeth might be the cause of her complaint, Mr. Power ordered them to be extracted. This was accordingly done at two sittings, the patient being under the influence of gas and ether. The ptosis thenceforward steadily diminished in both eyes, but to a most marked degree in the left. Ten days from the extraction of her stumps—nine in number—the palpebral fissure was wide enough to expose more than half her cornea, and she could see to read and to find her way about without any bending back of her head.

EMBOLISM OF THE ARTERIA CENTRALIS RETINÆ.

(Under the care of Mr. VERNON.)

R. H——, aged seventeen, a well-nourished and healthy girl, awoke one morning with pain in her right eye, which she found was blind. She visited the hospital next day. The pupil of the right eye was dilated and insensitive to light, that of the left side reacted well. On ophthalmoscopic examination the optic disc was found to be hazy, its margins ill-defined, the retinal vessels exceedingly small, almost invisible at some spots, at others filled with small dark clots. On the following day effusion was noticed round the "cherry spot" at the site of the macula lutea. The effusion looked like a bluish-white mound, with a dark red centre. She had no perception of light in the right eye. The left eye was normal, and its pupil reacted well to light. The effusion round the yellow spot or disc increased for some days, and a small hæmorrhage appeared at the outer margin of the disc. The whole fundus appeared almost a facsimile of the picture in Liebreich's Atlas. This effusion gradually disappeared. The cherry spot first extended, so that at the end of the first week the white clot in the fovea had become obliterated. At the end of a fortnight the disc was very white, its vessels extremely small, the whole fundus dark, and a trifle hazy where the effusion had been. After three weeks she said she could appreciate light with her right eye; no further improvement, however, took place. Her blood was examined by Dr. Harris, and found normal. Three and a half years ago she suffered from rheumatic fever, followed in a month by chorea. She was then in the hospital, and on referring to the notes of her case it was found that there had been no cardiac affection. On examination, however, the first sound of the heart was found prolonged and rough at the apex and audible behind. Two years ago she had an attack of scarlatina, which was followed by chorea. Her catamenia were regular, and there were no symptoms of embolism in any organ but her eye. Neither did she at any time present constitutional symptoms of such an event, unless, indeed, adopting the theory of Kirkes, we look upon the two attacks of chorea as evidences of cerebral multiple embolism.

ECTOPIA CENTRUM; IRIDODONESIS; MYOPIA AND OLD CHOROIDITIS.

(Under the care of Mr. VERNON.)

F. P——, aged nine, a thin but well-nourished girl, of healthy appearance, was admitted complaining of dimness of vision. Her sight had never been good, but appeared now to be growing worse. The external parts of the eye and its appendages were natural. The pupils were dilated, and the irides trembled, especially at their upper parts, in a most marked manner on the slightest movements of her head. The anterior chambers were deep. On focal illumination the right iris was seen to be finely fringed at its pupillary margin, and one or two very fine darkish-coloured bands or filaments crossed the upper and outer part of the pupil in a direction downwards and inwards. The catoptric test gave three images, and it was not until direct examination was made with the ophthalmoscope that the crescentic edge of the partially dislocated lens could be seen crossing the upper and outer part of the pupil. The space between this and the iris was too narrow to permit of the fundus being examined through it, and it also accounted for the fact that the patient had no monocular diplopia or polyopia. There were large posterior staphylomata in both eyes. Her vision was, when unaided, only equal to the seeing of large objects and counting fingers at a foot and a half, and could only be improved by —8 D v —18 D in the two eyes respectively up to $\frac{20}{100}$. There was no history of injury or of any inflammation of the eyes. The cause of the dislocation was obscure. It might have been congenital, as in the cases recorded by Mr. Dixon in the London Ophthalmic Hospital Reports, vol. i., p. 55, and it further resembled these cases in the presence of myopia. On the other hand, the evidences of past choroiditis and the filamentous bands crossing the pupil suggested a pathological cause—viz., the weakening and relaxation of the ciliary processes by choroido-iritis, probably intra-uterine and syphilitic.

CUMBERLAND INFIRMARY, CARLISLE.

TWO CASES OF WOUND OF THE WRIST-JOINT TREATED ANTISEPTICALLY.

(Under the care of Dr. LEDIARD.)

FOR the following notes we are indebted to Wilfrid Wilson, M.B., and Archibald H. Veitch, M.B.

CASE 1.—Joseph H——, aged twenty-four, a dyer, was admitted on October 8th, 1880, suffering from a wound of the wrist-joint, which he had got when shifting a strap in connexion with a drum which works the beetles. His hand was caught by the strap and drawn into a pulley. The wound extended across the posterior aspect of the wrist. The tendons of the extensor communis digitorum, the extensor carpi radialis longior and brevior, the extensor indicis, and the extensor secundi internodii pollicis were torn away from their muscles and were hanging out of the wound to the extent of two inches. The other extensor tendons escaped. The joint between the radius and the first row of carpal bones was completely laid open, and the hand was dropped to a right angle. The cartilage of the scaphoid bone was lacerated and covered with dirt. The radial artery, as it lay between the extensor carpi radialis longior and the extensor primi internodii pollicis, was laid bare to the extent of an inch, but was uninjured. The amount of blood lost was small. The man was taken into the operating-room to have his hand amputated, but Dr. Lediard decided to make an attempt to save it. The wound was thoroughly washed out with 1 to 20 of carbolic lotion; the edges were drawn together with carbolised silk, and it was dressed with the ordinary antiseptic gauze dressing. A trial was made to unite the divided tendons, but the muscles were too far retracted. Evening temperature 100·8° F. On the 9th the wrist was dressed; the wounds were looking well. Morning temperature 99°, evening temperature 100°; the anterior splint was applied. On the 10th the morning temperature was 99·8°.—11th: Temperature normal. On the 13th the limb was again dressed; temperature normal.

After this date the wound was dressed weekly. The temperature remained quite normal.

On November 22nd the wound was quite healed, and the patient was discharged. He was able to extend both joints of the thumb, and the second and third phalanges of the fingers, but not the first phalanx. The mobility of the wrist was perfect. He went to work after providing himself with a leather support laced round the wrist and palm.

CASE 2.—Jane O——, aged fifteen, was admitted Dec. 1st, 1880, with wounds of the palm of the hand and anterior aspect of the wrist which had been inflicted about an hour before by a biscuit machine. There was a semicircular wound about an inch and a half in length over the lower end of the radius, penetrating deeply into this bone throughout its entire breadth, and dividing the radial artery. Immediately below this wound was another smaller one, which completely opened up the scapho-radial articulation. A wound over the ulna divided the ulnar artery. There was a deep circular wound in the centre of the palm, and between this and the wounds on the wrist a similar one, which divided the annular ligament, the central flexor tendons, and the median nerve. There were numerous small wounds on the fingers. There was a moderate amount of hæmorrhage. The radial and ulnar arteries were ligatured with catgut and the wounds were syringed out with 1 to 20 of carbolic lotion for half an hour. A few silk stitches were inserted, and it was dressed antiseptically. The wound was dressed daily, and the temperature remained normal till the evening of December 5th, when it rose to 101°; at the same time the patient complained of pain in the forearm. On Dec. 6th the morning temperature was 101°. When the wound was dressed the radial wound was inflamed, and redness extended up the forearm, owing to the discharge not having a free exit; the stitches were removed. On the 7th the morning temperature was 100°. The wound was again dressed. The pain had left the forearm, but persisted in the hand; sensibility to touch was absent in the hand, except in the fourth and half of the ring fingers. On the 8th the wound was dressed and the temperature was normal. On the 14th sensibility to touch was partially restored in the hand; the pain still persisted.

After this date the wound was dressed weekly. On the

20th several pieces of tendon about an inch and a half long came away from the palmar wound. On Dec. 28th sensibility was quite restored in the hand, and the pain had left the palm. On Jan. 23rd all the wounds were quite healed. The mobility of wrist was perfect. The patient had slight power of flexion in the fingers, most marked in the fore-finger. She was discharged Jan. 26th, 1881.

TOXTETH WORKHOUSE HOSPITAL, LIVERPOOL.

STOKES'S SUPRA-CONDYLOID AMPUTATION.

(Under the care of Dr. Lyster.)

For the following notes we are indebted to Mr. N. Roberts, M.B., C.M., house-surgeon.

T. N——, aged sixteen, was admitted on Dec. 20th, 1879, said to be suffering from erysipelas of the left leg. The previous history of the patient was that he had recently been discharged from a fever hospital, where he had been treated for typhus. He said that on admission into the fever hospital he had a little pain in this leg, which seems to have been due to a sore on one of the toes, resulting from the friction of a badly-fitting boot. It soon became evident, after admission into the Toxteth Hospital, that there was inflammatory mischief going on in the shaft of the tibia. Free incisions down to the bone were made, and the usual treatment for such a condition adopted with marked relief to the patient temporarily, but without materially affecting the progress of the disease, which now assumed a more chronic aspect than heretofore. Ere long it became evident that the bone was dead, and it only remained to wait for a separation of it from the living tissues, the boy being kept the while in as good a condition as good diet, cod-liver oil, and tonics could induce. By the month of May the condition of the leg was much worse, and it was telling so much upon the general health of the boy as to suggest operative interference. The whole leg below the knee was very much swollen, with a large number of sinuses leading down to the new bone, through the cloacæ in which the dead bone could be felt by means of the probe, but the soft tissues of the limb were so involved, and their vitality so low as, together with the general condition of the patient, to make sequestrotomy a doubtful procedure, and to suggest amputation as the proper course to be adopted.

The particular operation resolved upon was Stokes's supra-condyloid amputation of the thigh, which was performed by Dr. Lyster on June 3rd with highly satisfactory results. The operation was performed under strict Listerian antiseptics. The anterior oval flap containing the patella was easily obtained, and the cartilage of the patella was removed without much difficulty by the aid of the saw, supplemented by that of the bone forceps. The femur was divided three-quarters of an inch above the articular surface from the patella, the surface of section being the dense cancellated tissue of the end of the bone. The vessels were tied by catgut ligatures, and a somewhat troublesome capillary oozing was controlled by deluging the flaps with hot carbolised water. The anterior flap was turned down, so that the patellar surface, denuded of its cartilage, was closely apposed to the sawn end of the femur, which apposition was further secured by means of a strong catgut ligature through the dense structures about the bones. The wound was closed by catgut ligatures, drainage-tubes were introduced, and the usual antiseptic dressings were applied. The patient was put to bed, and a sixth of a grain of morphia injected subcutaneously. The patient slept for five hours that night.

On the following morning the temperature was 99·8°, and in the evening 100·2°.

On June 5th the temperature in the morning was 99·8°; evening, 99°. From this time forward the temperature never rose above 99°.

The dressings were changed the day following the operation and on three other occasions before they were altogether discarded, which took place June 17th, the wound having then entirely closed with the exception of a slight superficial abrasion, and this healed up in a few days. The stump was entirely free from pain, even on moderately rough handling, at this early date. Two months after the operation he left the hospital, having been kept for some time so as to get used to his wooden leg, the stump being as perfect as any stump could be, and his general health excellent.

Remarks.—A point of some interest in this case is that an intractable disease seems to have been lighted up in the bone by an attack of typhus, in a lad otherwise healthy. This is sufficiently out of the common to merit notice. On dissecting the leg, the entire shaft of the tibia was found to be necrosed and encased by the new bone, whilst the condition of the soft tissues showed that amputation was the only course that could have been pursued with any success.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Combined Carcinoma and Adeno-fibroma of the Breast.—Hyaline Myxoma of Breast.—Cranium and Brain from a Hydrocephalic Adult.—Dermoid Tumour of Soft Palate.—Lupus Erythematosus.—Squamous Epithelioma of Upper Jaw.

The ordinary meeting of this Society was held on the 5th instant, Dr. Wilks, F.R.S., President, in the chair. It will be seen that a great variety of specimens were shown.

Mr. Rushton Parker showed a specimen of Carcinoma and Adeno-fibroma of the Breast from a married woman, forty-two years of age, who came under his care in October, 1880. The growth had been noticed for three years. It occurred as a movable mass, the size of a walnut, in the upper part of the left breast; the nipple and lymphatic glands being free. He excised the growth, but as after removal it showed evidence of being cancerous, the whole gland was removed. The age of the patient and the size of the growth were in favour of its being cancer, nor was its duration inconsistent with this view; but its mobility was in favour of its being a chronic mammary tumour, and had the patient been under thirty it might well have been thought to be of that nature. In dissecting the breast from the subjacent fascia a small bursa was met with, into which projected a white nodule of adeno-fibroma. The structure of the main mass was that of adeno-fibroma, wavy fibrous tissue between acini and ducts; but in another lobe columns of aggregated cells within an alveolar stroma reproduced the characters of carcinoma. He supposed it was rare to find such a combination, but Langhans had recorded two cases; and he wished the specimen to be referred to the Morbid Growths Committee.

Mr. Parker then showed a specimen of Hyaline Myxoma of the Breast, which had been noticed by the patient for about seven or eight years. It attained the dimensions of a good-sized orange, and occupied the upper and outer corner of the breast. It was a lobulated, gelatinous, opalescent-looking growth, with a central cyst, and several smaller cysts with intracystic growths. Some of the lobes were of a yellowish-white appearance, others glistening. Microscopically it was a pure adeno-myxoma, and was peculiar in its hyaline character, differing from the more common variety of the softer chronic mammary tumours, with myxomatous stroma. He also showed some microscopical specimens of Adenoma of the Breast. One was from a patient sixty-three years of age, and showed fibro-alveolar arrangement with spaces containing sebaceous material varying in size from a pin's head to half the diameter of a pea. He remarked that increasing pathological knowledge showed that these growths were not so rare as used to be thought. Another specimen was of an intracystic protrusion from a simple cyst of the breast. It appeared as if a sort of hernia of the mammary gland substance had occurred into the cyst in consequence of a blow. He also showed section of an adenoma of the tongue. It grew at the back part of the organ in a young woman, and was a pure adenoma—a very rare disease. Another adenoid growth was one which grew between the skin and mucous membrane of the nose of a man sixty-seven years of age. It was of three or four years' duration, and exhibited round-celled infiltration between the acini.—Mr. Butlin said that the portion of the growth under the microscope in the first case was undoubtedly carcinomatous. A pure adenoma, such as one of Mr. Parker's specimens, was very rarely met with. The figure given by Rindfleisch of "adenoma" seemed to him to be carcinoma, for the acinus was filled with cells. In an adenoma the acini are lined by epithelium, and not filled with it as in carcinoma.

Dr. BRAILEY exhibited the Cranium and Brain of a Hydrocephalic Adult, which had been presented to the Museum of the Cambridge University, and dissected by Mr. Anningson. The subject was a woman, fifty-three years old, who died of pleuro-pneumonia. For the last nine years she had been an inmate of a lunatic asylum, and for some time past had suffered from attacks of vomiting and epileptiform seizures. The bones of the extremities and thorax were small and ill-developed, and there was a lateral curvature of the spine. She had possessed a certain amount of intelligence, being able to converse and sing hymns; and was of violent temper. The cranium measured twenty-seven inches in horizontal circumference, and was completely ossified; there were many Wormian bones. The brain nearly filled the cranial cavity; the third and lateral ventricles were greatly dilated, the commissures enlarged. In the posterior fossa, indenting the bone on the right side, was lodged a thin-walled membranous sac, with clear contents, measuring one inch across. It came close to the foramen magnum, and was attached to the dura mater. The points of interest in the case were the unusual longevity attained by the woman, the size of the cranium, its complete ossification, the patency of the aqueduct of Sylvius, the existence of a cyst beneath the cerebellum, and the fair amount of intelligence that the subject exhibited. Dr. Brailey referred to the well-known case of Cardinal, whose skull, thirty-three inches in circumference, is in Guy's Hospital museum, and to the specimen presented by Liston to the College of Surgeons, from a subject twenty-five years of age, the skull in that case being thirty-six inches in circumference with great development of Wormian bones. —Professor HUMPHRY, who had seen the specimen dissected, offered an explanation of the occurrence of the sac beneath the tentorium—the specimen in all other points resembling other specimens of hydrocephalus of the adult—the cranium being dilated everywhere except its basal part. The dilatation of the membranes of the brain leads to an elevation of the falx, which draws up the tentorium so that it may become quite vertical. This vertical position of the tentorium is to be seen in a specimen in the Cambridge Museum, so that the posterior cerebral lobes considerably overlap the cerebellum. The subtentorial space devoted to the cerebellum is thereby increased; and Professor Humphry had noticed that this was compensated for in the specimen above referred to by the development of connective tissue between the dura mater and arachnoid. In the present case the whole tentorium was raised, the lateral sinuses and torcular Herophili taking a higher position than normal; and he presumed the sac containing fluid was developed to fill up the space unoccupied by the cerebellum. It was a sort of lymph sac thus mechanically produced. —Dr. BACON, who had the patient under his care during her life, remarked that she had a fair amount of memory, could repeat hymns taught her in childhood, and could converse intelligibly. She had a very irritable temper, and great want of self-control. He remarked upon the diminished size of the rest of the skeleton, and upon the unusual age attained by the patient. Most of the cases recorded died before thirty years of age. There is one case recorded in the *Journal of Mental Science* for 1879, where the subject was thirty-eight years old, and whose skull measured twenty-four inches in circumference.— The PRESIDENT had some years ago published three cases in the *Journal of Mental Science*, one of which is also described in his work on "Rest and Pain" by Mr. Hilton, who ascribed the condition to closure of the fourth ventricle. Dr. Wilks himself thought that an excessive amount of fluid in the brain was often due to inanition, and occurred in rickety children with large heads and low mental capacity. The fluid was often reabsorbed; as, for instance, in a young man, now of good intelligence and normally sized head, who when a child had the characteristics of hydrocephalus and curved legs, so that he was thought to be rickety. The large head with overhanging forehead so common in the criminal classes could not be attributed to a greater increase of natural brain, but was probably due to fluid.—Professor HUMPHRY, in reference to a remark by Dr. Wilks, said that he certainly believed many people with large brains did not use them to their full capacity; but his observation was that our far-off ancestors had large brains which they did not seem to have used so much as they ought. He believed the cause of hydrocephalus to be due to a want of the normal balance between secretion and absorption of the fluid, the power by which the fluid is poured into the ventricles exceeding the resisting power of the skull, just as in a hydrocele the fluid is secreted in excess in spite of the resistance offered by the tunica vaginalis. But what it was that determined the balance being normally so accurately maintained was unknown.—Dr. LONGHURST asked whether the cyst interfered with the function of the cerebellum. — Professor HUMPHRY explained that it appeared to have been developed simply to fill space which would otherwise be unoccupied.

Dr. HALE WHITE showed a specimen of Dermoid Tumour of the Soft Palate, from a child three years of age who had had some difficulty in swallowing. The uvula was much hypertrophied, and lay in front of the tumour, which apparently sprang from the upper surface of the soft palate. The tumour was two inches in height, and had a wide base; it was freely movable, and was removed by Mr. Morrant Baker. It was found to be soft in consistency, except on one surface, where a plate of cartilage existed. Microscopically it reproduced all the cutaneous structures—epidermis, papillæ, corium, and fat cells, but no elastic fibres. There were also many hairs lodged in follicles, into each of which a single sebaceous gland opened. The plate of cartilage was invested by a dense layer of fibrous tissue; its matrix was very scanty and fibrillated, the outer layers of the cartilage being composed of nucleated stratified cells. Dr. White referred to a similar growth from the basilar process of the occipital bone, recorded by Dr. Abraham in the *Journal of Anatomy*, vol. xv., and to one on the palate of a new-born child described by Dr. Kidd in 1856. As to the origin of the tumour in the present case it might have grown in connexion with the Eustachian tube; but its epiblastic nature was sufficiently accounted for by its occurrence in front of the junction of the hypoblast and epiblast. It might be an instance of "reversion," for in the rabbit there occur in this region four tufts of hair—two above and two below.—Mr. RUSHTON PARKER had lately seen a similar dermoid growth removed by Mr. Bickersteth from the pharynx of a child, depending behind the soft palate.

Mr. MALCOLM MORRIS exhibited a case of Extensive Lupus. The patient was a woman sixty-four years old, who had enjoyed good health until 1858, when she became very weak, and remained so until 1860, when she had an attack of general dropsy, which gradually disappeared from all parts except the legs. About the end of that year a brown patch appeared on the front of the right leg, ultimately ulcerating. Other ulcers appeared—one on the calf being large and slow in healing. The skin in their vicinity became red and raised; and similar patches appeared elsewhere below the knee. During the next five or six years more patches appeared on other parts of the body, the left leg, and arms. In 1871 a small spot of like character appeared on the vertex of the scalp, slowly spreading towards the face, passing to the nose and cheeks, and destroying the sight of the right eye. For the last few years the disease has spread but little. At present there are two ulcers with sharply-defined healing margins on the right leg, the larger being on the side of the ankle. Cicatricial tissue covers the front of the ankle, the side and back of the leg. The foot, including the sole, is dry and scaly; and a similar hypertrophied condition of the skin occurs on the leg and thigh, terminating in an abrupt line (in parts slightly raised and red), about three inches from the hip-joint. Within the last few months three patches, red, tuberculated, and scaly, have appeared on the left leg; and others occur on each arm, on the head and face; in front of a line extending from one ear to the other the skin is replaced by scar-tissue, all the hair-follicles being destroyed except on a small area to the right of the middle line. The surface is smooth, shiny, and slightly scaly. There is some contraction, but the skin is not adherent to the bone. The disease extends over both sides of the face and neck—attacking the forehead, nose, and cheeks, and ending in an abrupt raised margin on either side of the chin. The left lower eyelid is drawn down and everted. Mr. Morris suggested that the disease of the head and face was lupus erythematosus, which rarely commenced so late as fifty-four. Mr. Tay reports a case where the disease began at fifty-one. The spreading ulceration on the legs indicated a different condition. Besides, lupus erythematosus invariably commences on the face, and the leg was affected many years before. Was this primary ulceration also lupus? The slow course of the attack and its superficial character were against the hypothesis of syphilis, of which there was no history.—Mr. HUTCHINSON said the case was one of a rare form of lupus, and mainly a superficial form; but he did not think it was erythematous lupus, its superficial character alone differentiating it from ordinary lupus, its tubercular character (e.g., on the arm), and the slow serpiginous ulcers on the legs being sufficiently typical. There was another rare form of lupus which, from its superficial character and slight discharge, much simulated eczema.—Dr. THIN some years ago saw a case of erythematous lupus on the forearm, spreading towards the shoulder, and limited by an abrupt line. He regarded Mr. Morris's case as one of lupus erythematosus, which he would distinguish from erythematous lupus. In lupus proper there was a tubercular formation due to aggregations of cells, which were not met with in lupus erythematosus, a specifically distinct affection both clinically and anatomically. The change in lupus erythematosus creeps along the papillary layer, but leaves unaltered the pars reticularis of the corium.—Mr. HENRY MORRIS said that there was now under his care in one of the cancer wards of the Middlesex Hospital a woman who had suffered from lupus for six or seven years. The disease had destroyed the lip, nose, both eyes and eyelids, and one ear, and had resulted in extensive cicatrisation. The whole of the area occupied by the ear was now a white cicatrix. Ulceration occurred at different times, and then healing took place. The disease was limited to the head and face, and was somewhat deeper than in the case exhibited, but it resembled that in its limitation on the scalp to its anterior part.

Mr. BUTLIN showed a specimen of Squamous Epithelioma of the Upper Jaw, removed from a man sixty-two years old, admitted into St. Bartholomew's Hospital in November, 1880, for carbuncles on the back. In December he complained of a sinus in the upper jaw, which had been discharging for some time before. On Dec. 29th Mr. Willett explored this sinus, which opened into the alveolus of the second right molar tooth, and was thought to be due to carious bone. Exploration of the antrum through this sinus showed that cavity to be partly filled with pus and blood, and to be lined by soft granulation-like material. There was no swelling; but the condition of the antrum was thought to be suggestive of malignant disease. At the beginning of February Mr. Butlin scraped out some of the contents of the antrum, and found in the scrapings altered epithelial cells and cell-nests. Accordingly, on Feb. 8th, he removed the whole of the maxilla, and found that the disease not only filled the antrum, but invaded the orbit and spheno-maxillary fissure, and had made its way beneath the temporal muscle. Yet the only external indication was a slight puffy swelling, which had appeared beneath the orbit in January. The growth was a pure squamous epithelioma, and was remarkable for its insidious character, and widely-destructive course within a comparatively short space of time. It belonged to the class of maxillary new growth called by Reclus "epitheliome terebrante" (*Progrès Médical*, 1876), and described by that writer as starting from the alveolar process. In each of Reclus's cases the disease was first thought to be caries, and ran a rapid cause. The disease probably starts from the alveolus of a tooth which has become carious, or from which the tooth has fallen out, and thence spreads into the jaw, and does not start in the antrum, which is lined by cylindrical epithelium. It was not, therefore, necessary to trace its origin back, as Reclus does, to an alveolar cyst, or to the remnant of the epithelial masses of the primitive tooth sac. There was no affection of the glands or other internal organs in this case. The only other instance in English literature is one described by Mr. Lawson at the Clinical Society in 1873, as a well marked squamous epithelioma, which Mr. Hulke suggested as beginning in the alveolar process.—Mr. RUSHTON PARKER did not think this form of disease very rare.

The following card specimens were shown:—Odontoma of Left Second Lower Molar, by Mr. Rushton Parker; Old Outward Dislocation of the Patella, by Mr. Charles J. Symonds; Sequestrum of Clavicle, Osteo-Sarcoma of Lower End of Femur, and Cancer of Mamma following Eczema of Nipple, by Dr. Macnaughton Jones (through Mr. Hutchinson); Epithelioma of Tongue; Gangrene of Lung after Excision of Tongue, by Mr. Royes Bell.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

Pseudo-hypertrophic Paralysis.—The Digestion of Fats.—Disseminated Syphilitic Meningitis.

At the meeting on March 28th the chair was taken by the President, Dr. BROADBENT, who exhibited a man, aged fifty-one, who had been eleven years a soldier and subsequently followed the occupation of a gardener. At the present time he was a patient in St. Mary's Hospital. For two years he had a rolling gait, and gradually became unable to raise himself from the recumbent or sitting posture. The man presented all the characteristics of pseudo-hypertrophic paralysis. As he walked he swayed from side to side and was unsteady on his feet; in short, he exhibited just the condition of the children who were shown at the last meeting of the Society. The tensor vaginæ femoris was large and in an energetic condition; there was extreme lordosis. The calf muscles did not respond to continuous or interrupted currents. Dr. Broadbent asked what was the nature of this paralysis. It was not progressive muscular atrophy, nor was it an instance of the adult form of infantile paralysis; the lipomatous development so often associated with this kind of paralysis he did not regard as an essential feature. He would venture to remind the Society that at one time infantile paralysis was considered to be confined to children, but such is not now found to be the case.—Mr. ADAMS remarked that the case certainly simulated Duchenne's paralysis thoroughly both in attitude and movement, but it was against his experience to find the disease commencing so late in life. It is essentially a disease of children, a congenital affection.—Dr. GILBART SMITH said that in 1862 Trousseau had called locomotor ataxy Duchenne's disease, but now authorities seemed undecided as to what the term "Duchenne's disease" really referred.—Dr. MACKENZIE had a patient, an adult match-seller, with similar symptoms. He also regarded the fatty development as an accidental accompaniment, and as more apt to exist in Duchenne's paralysis of children than of adult age.

Dr. J. MILNER FOTHERGILL made some remarks upon the Digestion of Fats, and of the value of conveying them into the stomach in the form of an emulsion; he considered that the best emulsifying agent was bile, and that the small quantity of bile required for this purpose would not be irritating to the stomach.—Mr. DORAN asked if the distaste for fats in phthisical patients was not often due to the inability that existed to digest such foods.—Dr. THOROWGOOD hoped the result of the administration of these emulsions would be made known. He regarded with favour the combination of malt extract with cod-liver oil, which he has employed for some time.—Mr. OWEN had used an emulsion of oil and solution of potassium. Only a small quantity of the alkali was required, but he was not prepared to say that its administration was followed by any markedly satisfactory results.—Dr. FOTHERGILL, in reply, said that he had brought forward the whole question in a purely tentative manner, and hoped that as time went on some definite result might be obtained.

Dr. MACKENZIE read notes of a Case of Disseminated Syphilitic Meningitis, illustrating the value of Mercurial Treatment. The patient, after the customary prodromata, came under treatment for great tremor of the hands and legs, occurring on voluntary movement, pain in all the limbs, formication in the hands and feet, stiffness of hands and fingers, and pain in left side of head. She had a characteristic syphilitic tertiary eruption on the forehead and forearm. Iodide of potassium in ten, and, later on, in twenty grain doses, failed, even in combination with the internal administration of the perchloride of mercury, to ameliorate the nervous symptoms, though it sufficed to cure the syphilide. Mercurial inunction and perchloride of mercury, internally, were then employed with rapid relief to the symptoms; salivation was produced, and the mercury had to be suspended for a short time, but was resumed afterwards, mercurial inunction alone being employed cautiously and intermittingly, on account of the great susceptibility of the patient to its influence. All the symptoms gradually cleared off, leaving the woman weak. Fifteen months later the improvement had not only been maintained, but was greater. The case was brought forward to illustrate the value of mercury in such instances, mercury often acting more quickly and certainly than iodide of potassium; and, as in this case, when the iodide had failed to produce any favourable influence, inunction was the form recommended in syphilitic nervous affections, as by this means the largest quantity of mercury could be introduced into the system with the least disturbance. The first thing was to use it boldly, the next to continue its use sufficiently long.—Dr. DOWSE thought it strange there was no mention of retinal changes in Dr. Mackenzie's case; it was his experience that generally more faith was placed, and properly so, in the use of preparations of mercury than in those of potassium.—Dr. HERON asked why the author had chosen the perchloride of mercury before all the other preparations of the metal. Some practitioners went so far as to say that the perchloride was therapeutically useless; was there any family history of neurosis?—The PRESIDENT noted one peculiar and interesting character of the spinal affection—syphilitic myelitis, which here resembled very closely diffused sclerosis. It was the first time he had heard a simulation of these two important diseases. He would have begun with the iodide of potassium, but if the cure was delayed he would have prescribed mercury.—Dr. MACKENZIE replied that in the later stages of the disease mercury is required, then solution of the perchloride is of the greatest therapeutic value.

The meeting then adjourned.

EPIDEMIOLOGICAL SOCIETY.

AT a meeting of this Society held at University College on March 2nd, Sir Joseph Fayrer, K.C.S.I., M.D., in the chair, Surgeon-General Dr. John Murray read a paper on the "Influence of Fairs, Famines, Floods, and Seasons on the Development and Diffusion of Cholera in India," which was accompanied by several very elaborate statistical tables. Tables Nos. 1 and 2 illustrated the effect of fairs by showing the mortality caused by the epidemics which originated at Hurdwar in 1867 and 1879. No. 3 showed the mortality which follows the great fair at Allahabad in the eastern districts of the north-western provinces, Oudh and Behar. No. 4 related to the mortality in the delta of the Ganges after the cyclone wave of 1876. No. 5 showed the mortality from cholera accompanying the famines in Madras in 1866 and in 1875-6-7. These tables were so arranged as to contrast the mortality in the epidemic years with that in ordinary years, and also to show that in some years the disease was almost non-existent. An abnormal increase of the disease must be induced by some special cause; and those causes now under consideration range over a wide area, and involve a population of more than thirty millions under each head, and must therefore be of the utmost importance in the history of the disease. The statistical returns of the civil population show the course of the disease more clearly than the records of military hospitals, though the latter have been kept from the beginning of the present century. The period is longer, but the number under observation is comparatively small, and the disease is under the restraint of strict medical and sanitary treatment. The military also are exempt from the influence of floods and famines, and almost so from that of fairs, but the influence of season is common to all. In considering the subject of fairs the epidemics following the Koomke Mela at Hurdwar were minutely traced, accurate returns having been obtained from all the civil surgeons of the appearance and progress of the disease in their various districts in 1867, and in all cases the dates corresponded with the arrival of the pilgrims at the ordinary rate of travelling. In 1879 the dates coincided in all instances except in Scinde, where its arrival was accelerated by about two months, which may be attributed to the introduction of railway travelling, more than a hundred cases of the disease having been removed from the trains in a dead or dying condition. The great fair which is held in February at Allahabad is followed by an analogous diffusion of cholera. The fair is held six weeks earlier than that of Hurdwar, and the epidemic appears six weeks sooner. These reiterated facts prove the danger arising from these fairs, but their suppression cannot be resorted to by Government on account of the religious feelings of the natives. To control them and establish strict sanitary supervision is all that can be recommended, though less efficacious. Dr. Cuningham denies the transmission of the disease by the pilgrims, but rather considers it existed in some aerial form in the villages, and attacked the pilgrims who were peculiarly susceptible of its inroads; so that, instead of the pilgrims importing the disease which affected the inhabitants, the village infected the pilgrims. This opinion rests entirely on the theory that such aerial poison exists, of which there is no proof or probability. The next division of the subject referred to the severe epidemic which commenced two days after a cyclone wave overwhelmed the eastern part of the delta of the Ganges on October 31st, 1876. It proved fatal in the following four months, in the three coast districts, to 75,459 persons. The disease spread to the surrounding districts, and the mortality during the year amounted to 159,733. In Table No. 4 the year is counted from July 1st to June 30th, to show the course of the epidemic, which culminated in January, and rapidly subsided after February. The course of the disease in this epidemic appears to be an exaggeration of the usual course of cholera in the delta, which differs essentially from that in the other provinces of Bengal, Orissa, Behar, and Assam, and also from its course in the Upper Provinces, Scinde, Punjaub, Central Provinces, and Bombay, where the cold season is a period of quiescence, while it is at its height in the cold season in the delta of the Ganges. There was a partial cyclone wave on the southern coast of Chittagong in 1879, followed by a similar outbreak of cholera two days after the subsidence of the water. The influence of famine on cholera was shown in Madras, where there was a severe famine in 1866, when the mortality from cholera amounted to 197,977. A more prolonged famine occurred in 1875-6-7, when the mortality from cholera rose to 617,869. The course of the disease in both famines was identical, the mortality being greatest when the price of food was highest. It was little influenced by season, and was probably aggravated by the collection of crowds of starving people at the famine kitchens and its spread on their return to their homes. The influence of season is shown in the returns from the military and civil hospitals, which are epitomised in Tables 6, 7, and 8. They extend over a longer period—viz., from twenty-six to seventy-four years, but include a much smaller population. The season of the prevalence of the disease, as it appeared from the tables, differs essentially from that shown by the tables relative to the civil population in the epidemic years. In the military hospitals of the Upper Provinces and the Punjaub the greatest mortality is at the commencement of or during the rainy season—i.e., from June to September, whereas the greatest mortality amongst the civil population commences in April. By removing the epidemic years from the civil tables, the returns for the other years show a seasonal increase in the mortality coinciding with that in the military hospitals, but this is obscured by the excessive mortality of the epidemic years.

In the discussion which followed, the President, Dr. Norman Chevers, Dr. White, Dr. Duka, Dr. Dickson, Mr. Netten Radcliffe, Mr. Lawson, and Dr. Gordon took part.

A letter from Mr. J. Lawrence-Hamilton was read on the subject of artificial production of vaccine lymph.

OBSTETRICAL SOCIETY OF LONDON.

AT the meeting on Wednesday, March 2nd, 1881, Dr. Matthews Duncan, President, in the chair,—

Dr. GODSON showed, for Dr. J. Dewar, a specimen of Interstitial Fibroid. The patient was a widow aged forty-three, sterile. Three years ago Dr. Dewar attended her for retroflexion. She wore a Hodge's pessary with advantage for some time; then it began to give pain, and had to be removed. About a year after she had an acute attack of pelvic peritonitis, which left the uterus fixed. She died rather suddenly from a second attack of peritonitis. The specimen showed a small fibroid in the anterior wall of the body of the uterus. The fundus was retroflexed, pointing downwards very markedly.

The PRESIDENT then delivered his inaugural address, which has already appeared in our columns.

Dr. BARNES read a paper on so-called "Missed Labour, with a case in illustration." The author commenced by stating that the term "missed labour" proposed by Dr. Oldham was not justified by the facts of that gentleman's case, which proved on autopsy to have been one of extra-uterine gestation. Discussing other cases of presumed missed labour, and accepting the arguments of Stoltz and Müller, the author affirmed that no authentic example of missed labour—this being taken to mean the prolonged retention in utero of a fœtus living at term—is yet known. He cited examples of the retention of the ovum which had perished in utero at a previable age for some time, and notably until the arrival of the natural term of gestation. He related a case which came under his own care. A lady aged thirty-nine had borne three stillborn children, the last of them five years ago, before consulting Dr. Veitch at Penang in December, 1872. Pregnancy dated from early in November preceding. The usual signs of pregnancy were manifested; she verified quickening, and up to the seventh month she felt movements of the child. About the eighth month, after a slight accident, a flow of blood came. Three weeks later another bleeding occurred, but no labour pains. Eleven months after the presumed date of conception she came to England. There was an impression that she might be suffering from fibroids of the uterus. She came under the author's care in December, 1873. Under chloroform, the cervix uteri having been dilated by laminaria tents, he felt what he took to be the interior surface of the uterus; the sound passed six inches. In January, 1874, some coloured discharges went on. Pieces of bone, which turned out to be bits of the spinal column, passed by the vagina. After dilatation by tents more bones were removed by fingers and forceps. In February this manœuvre was repeated, and by craniotomy-forceps the remaining parts of a fœtus, which appeared to have reached the eighth or ninth month of gestation, were extracted. Her health then improved, the discharges became less offensive, and the uterus gradually shrank as in ordinary involution, but more slowly, until it reached the common conditions of the non-pregnant state, and the patient perfectly recovered. The author submitted that this was a clear instance of the retention of a fœtus dying in utero at a viable stage for some months after the normal term of gestation had been reached, and that in this sense the term missed labour might apply. He cited the cases of Dr. M'Clintock and Dr. Hall Davis as corroborative.—Mr. SPENCER WELLS, who had seen the patient, asked if the case might not be explained on the assumption that the pregnancy was what had been called by some interstitial or mural, in which the ovum is arrested where the Fallopian tube passes through the uterine wall. He remembered that some attention had been given to this view at the patient's bedside, and thought that the subsequent history was quite consistent with this view. It was strengthened by a case he saw last year. A lady who believed she was in the fifth month of pregnancy was reduced to a state of extreme danger by constant pains and vomiting. Eminent men had said she could not be pregnant, because the cervical canal admitted the finger, and the sound could be moved freely to a depth of nearly five inches. Mural pregnancy was diagnosed, ergotine was injected into the substance of the cervix uteri; severe pains followed, and the expulsion of the fœtus, with perfect recovery.—Dr. ROPER thought that a reasonable explanation of these cases of so-called missed labour might be given from a point of view hitherto unnoted. He believed that most of them were originally uterine gestations, which during their course became partially, or wholly, extra-uterine in consequence of a degree of rupture of the uterus from external injury, or spontaneous giving way through degeneration of the uterine structure. The fœtus did not escape entirely, but to such a degree that ultimately a cyst was formed outside the uterus, the fœtus being partly within and partly without. The first symptoms were those of pain, coincident with some accident, and the pains of labour were always equivocal. The fœtus at this time died, and the pains subsided; then followed the history common to all—fetid discharge, putrilage, and bones. When an autopsy had been made an aperture had been found, connecting the cavities of the uterus and the cyst. The rigidity of the cervix in these cases was of interest, as illustrating uterine polarity. The fundus being injured fundal polarity was arrested, while cervical polarity remained in full force.—Dr. GERVIS, in corroboration of Mr. Spencer Wells's suggestion, mentioned a case of extra-uterine pregnancy, in which very unexpectedly, about the fifth month, delivery occurred per vias naturales. The practitioner in attendance, on introducing his hand, found a distinct cavity towards the left angle of the fundus, in which evidently the fœtus had lodged. He also referred to cases in which, when delivery was due, a few ineffective pains occurred, but delivery did not occur till three or four weeks later. He mentioned a typical case in which this occurred in successive pregnancies, with the result that instrumental aid was necessary, and the child was each time born dead. At her fifth confinement the effort of nature was supplemented at the ninth month, and a living healthy child born. In the sixth pregnancy there was again protracted gestation, and a stillborn child.

HARVEIAN SOCIETY OF LONDON.

AT the meeting of this Society held on March 17th, the President, Mr. Henry Power, in the chair, Mr. Bryant read a paper on Gastrostomy, which we publish *in extenso* elsewhere.

The PRESIDENT thought that in spasmodic stricture of the œsophagus this operation of gastrostomy would be useful, and related a case of a gentleman, aged fifty-six, spare and wasted, he took to Sir W. Fergusson many years ago. A large bougie was forced through the stricture into the patient's stomach, but he got worse and was nearly starved to death. Subsequently Sir J. Paget saw the case, but did not operate as he suspected cancer. Death soon afterwards took place. At the post-mortem no disease of any kind was discovered, and there was no stricture after death; in fact, it was a case of spasmodic stricture, which ended in death. Mr. Bryant's mode of operation would, he thought, have saved the patient.—Mr. W. RAYNER related a case of a gentleman who swallowed molten lead, and who recovered from stricture in the œsophagus after dilatation for two years by means of gradually increasing the size of the bougies.—Dr. CLEVELAND asked whether purgatives were given in this case.—Mr. BRYANT, in reply, asked Mr. Power whether chloroform had been given in his case.—The PRESIDENT thought not.—Mr. BRYANT related another case of cancer of the œsophagus in which he performed this operation. Two days after the operation the man drank off a pint of milk and swallowed some bread. Notwithstanding this he died seven days afterwards. The œsophagus was found to be completely divided in half by ulceration. The post-mortem, carefully made, failed to show how this result occurred. He thought gastrostomy was an operation justified in many cases, and insisted on the great importance of making a *small* opening.

Dr. GOWERS then read a paper "On the Nature of the so-called Tendon-reflex Contractions." He first briefly described and demonstrated these phenomena, and urged the use of the term "knee-jerk" instead of "patella-tendon reflex," an expression which was probably inaccurate. He pointed out a method by which this phenomenon, when it is in excess, may be conveniently demonstrated on a patient in bed—viz., by depressing the patella with the finger, and then tapping the depressing finger downwards; the quadriceps instantly contracts. The evidence in support of the commonly received view that the contractions are individually reflex from the tendons was then considered, and it was admitted that it proves that some reflex influence is concerned in their production. But it was pointed out how much there is in the phenomena which cannot be accounted for on the simple "tendon-reflex" theory. The phenomena of the clonus in thigh and calf were especially difficult to reconcile with this theory. The significance of the fact pointed out by Westphal that passive muscular tension is essential for the occurrence of the contractions was then insisted on, and it was demonstrated that a tap on the tendo Achillis is ineffective unless it increases its tension, and so affects the muscle. Moreover, in what the author had called the "front tap contraction," no stimulation of the tendon was possible. The most conclusive evidence was that supplied by Tschirjew, who divided all the nerves to the patella tendon, and still found that the tap upon it made the muscle contract. The evidence thus seemed conclusive that these contractions (including the knee-jerk) are not excited by stimulation of the nerves of the tendons, but that the stimulus originates in the muscle. Is not, it was then asked, the contraction local, as Westphal has always maintained? The evidence from the time-measurements of Burckhardt, Tschirjew, Brissaud, Waller, and the author were then considered, and regarded as strongly opposed to the reflex nature of the individual contractions, all known facts negativing the assumption that a reflex contraction could occur in so short a time as the 1-30th or 1-40th of a second. The discrepancy between the evidence on the one hand that the integrity of the reflex arc to, through, and from the cord is essential for the occurrence of the phenomena; on the other hand, that the individual contractions are of local origin, can, it was urged, only be reconciled by the theory that passive tension develops in a muscle by a reflex action, an extreme irritability to local stimulation, and perhaps also a slight tonic contraction. This view, originally put forward by the author as an explanation of the "foot phenomenon," is, he now believed, equally applicable to the knee-jerk. The afferent impulse from muscles when put into passive tension affects the consciousness, and may produce a true reflex action, but the interval before this reflex action the author had found to be three times as great as that before the local contraction, and equal to the interval before a skin-reflex (Burckhardt). It was urged, therefore, that it is most important to discard altogether the term "tendon-reflex." The phenomena are dependent on and indicative of a "muscle-reflex" irritability which has nothing to do with tendons. It was important, however, to employ a general designation which involved no theory. The common feature of these phenomena is that insisted on by Westphal, that passive tension is essential for their production, and it was suggested that they should be called *myotatic contractions* (*τατικος*, extended). The similar contractions occurring in the arm were then alluded to, and the paper concluded with an outline of the conditions in which these contractions become excessive or deficient.

The President, Dr. Dowse, and Dr. Cleveland spoke, and Dr. Gowers replied.

Reviews and Notices of Books.

Nouveau Dictionnaire de Médecine et de Chirurgie Pratiques. Tom. XXIX. POL—PRO. With 93 Figures. Pp. 796. London: J. B. Baillière, Tindall, and Cox. 1880.

AFTER a delay which, though not long, is yet unusual with the successive volumes of this valuable and well-arranged work, the twenty-ninth volume has made its appearance. The chief articles are—Polypi, by A. Heurtaux; Pulse, by M. Duval; Lungs (Poumons), by Duval, Merlin, Balzer, Gauchet, Letulle, Dieulafoy, and Homolle; Professions and Occupations, and the diseases incident to them, by Proust; and Prostate, by Campenon. The minor articles are — Polygala, by Héraud and Barrallier; Polyuria, by Cuffer; Popliteal Region, by Schwartz; Porta (Vena), by Straus; Potassa, by Prunier; Pourriture d'Hôpital (Hospital Gangrene), by Rochard; Protoxide of Nitrogen, by Blanchard; Prurigo and Pruritus, by Hardy; and Pomades, Potions, and Powders, by Villejean. The *pièce de résistance* is the article Lungs (Poumons), which has been committed by the editor to no less than seven hands. M. Duval takes the Structure, the Physiology having been already discussed under the head of Respiration; M. Merlin takes Wounds; M. Gauchet, Congestion, Hyperæmia, and Œdema; M. Balzer, Embolism, Pneumonoconiosis, and Hæmorrhage; M. Homolle, Abscess and Emphysema; M. Straus, Gangrene; M. Dieulafoy, Cancer; and M. Letulle, Neoplasms, and Vegetable and Animal Parasites; and even then Pneumonia and Pulmonary Tuberculosis are considered under special titles.

The black colour of the adult lung is now believed to be attributable to carbon absorbed from without; but M. Duval adduces one or two facts in proof of this with which we were not acquainted. Chevreul, he states, established its carbonaceous nature by demonstrating its combustibility, whilst Traube in a charcoal burner recognised particles of vegetable carbon which, when examined microscopically, exhibited the forms of the cells and canaliculi of Pinus Sylvestris. Robin and Pouchet, again, have shown that true melanic granules are rendered yellow and coherent when exposed for a short time to the action of boiling liquor potassæ. His account of the anatomy of the organ agrees essentially with that which was given long ago in this country by Dr. Waters, the description of the epithelium being given in accordance with his own observations. In the section on traumatic pneumonia it is stated that Klebs and Socin have both shown that in cases of wounds of the lung the inflammation is limited to the part injured, and that in the case of bullet wounds in particular the pulmonary tissue surrounding the traject of the ball was simply hepatised to the extent of two or three millimetres. Balzer gives some interesting details in regard to fatty embolism of the lung, a condition that appears to have been first recognised by Zenker in 1866, who observed it in a man who had been crushed between two waggons, but did not fully appreciate the importance of his discovery. In the same year Wagner recognised the presence of fat in the capillaries of the lungs, Busch showed the constant connexion that exists between fatty embolisms and fractures or other lesions of the osseous tissue, and attributed it to the disintegration of the fat cells of the marrow of the bones, and he corroborated Wagner's statement that fat particles might become the foci of chronic suppuration. Microscopic examination of the lungs rarely enables the diagnosis of fatty embolism to be made, but sections stained with osmic acid readily enable it to be accomplished. The affection is characterised by dyspnœa, increased rapidity of pulse, and great debility. Mucous râles are heard, but percussion furnishes no sign, and hæmoptysis is rare. The only remedy for the disease is the instant amputation of the injured limb above the level of the fracture and at some distance from it.

The section on Gangrene of the Lung by Straus is very interesting. The diagnosis of the affection can scarcely be said to date back further than Laennec, for in the scattered and imperfect notices that appear in previous writers it is difficult to recognise the special characters of the disease or to distinguish the examples they relate from fetid expectoration in cases of dilated bronchi, pleural affections, and the like. Laennec's chapter on the subject receives high commendation, and his division of gangrene of the lung into circumscribed and non-circumscribed is followed. The right lung is more frequently affected than the left in the proportion of 3 to 2, and it is more frequent in males as compared with females in the proportion of 11 to 4. The disease rarely becomes arrested, and recovery may take place, the necrosed tissue being discharged by a bronchus. Its cause is almost always exposure to long-continued cold when the bodily powers are weakened. The symptoms are then given in detail. The treatment of the disease has of late years greatly improved; instead of the leeches and derivative measures employed by Laennec in accordance with the fashion of his day, inhalation of turpentine evaporated with water was adopted by Skoda, and more recently the disinfectant plan has been very thoroughly carried out with the aid of the pulveriser with success.

The article on the Prostate is remarkably complete. The structure of the gland is given, with sketches of the anatomical disposition of the parts at the ages of twenty-five and sixty-five respectively. M. Campenon doubts the influence of inflammation and other diseases of the bladder in producing prostatitis, and states that he has often seen severe and long-continued attacks of cystitis run through their whole course without the prostate becoming involved. On the other hand, the influence of urethritis and of excess in sexual intercourse is indubitable, especially if the patient has any proclivity to rheumatic, arthritic, or scrofulous disease. In describing the characters of both acute and chronic prostatitis, as well as those of abscess of the gland, the views of Sir Henry Thompson are very generally quoted with approval, and M. Campenon everywhere shows himself to be familiar with English surgery. Some interesting statistics are given in regard to abscess of the prostate. It appears that, excluding his cases of accidental death, about one in seven dies, and about one in seven recovers with a fistula. The causes of death, in the order of frequency, are purulent infection, septicæmia, exhaustion owing to prolonged suppuration, peritonitis by perforation and by contiguity, the last two being occasional only. The treatment both of abscess and of its effects is given in detail, but presents no novel feature. The thoroughly well worked-up sections on cancer, tubercle, calculus, and hypertrophy of the prostate render this article a complete monograph on this subject.

Anatomy of the Arteries of the Human Body, Descriptive and Surgical, with the Descriptive Anatomy of the Heart. By John Hatch Power, F.R.C.S.I. Third Edition, by William Thomson, A.B., F.R.C.S., Surgeon to the Richmond Surgical Hospital, &c. With Illustrations by B. Wills Richardson. London: Longmans and Co. 1881.

This is a handy volume, containing, in addition to the descriptive anatomy of the heart and arteries, directions for the operations of ligaturing the arteries, and an account of the anastomotic circulation by which the supply of blood to the part below is carried on. A short historical account of some of the operations with lists of the ligations of the more important arteries and accounts of cases of very special interest are given. Both the anatomical and surgical information is stated clearly and accurately, and the book will be useful to the practical surgeon. The illustrations are many of them familiar, but good. If to the account of the pericardium a description of the operation of paracentesis pericardii, with a discussion of the best site for the needle puncture, had been added, and the best places for, and plans of, applying compression to the various arteries had been appended, the work would have been made much more complete, and brought more thoroughly up to date. We would suggest these improvements in a subsequent edition.

L'Encéphale: Journal des Maladies Mentales et Nerveuses. Sous la Direction de MM. B. Ball et J. Luys. No. 1. Paris: Masson.

This new addition to periodical neurological literature makes its appearance under able editorship. Its title is borrowed from its English contemporary, and its characteristics are announced as impartiality, a practical spirit, and scientific scepticism—"the negative virtue which teaches us never to accept a fact without controlling it, an idea without discussing it, an hypothesis without demanding proofs." Of the original articles the first two are by Professor Ball on "Functional Cerebral Ischæmia," in which he propounds the theory of vascular spasm as the best explanation of certain transient paralytic symptoms, and a study of "Intellectual Impulsions." Dr. Luys follows with a contribution to the pathological anatomy and histology of idiocy. A long and interesting sketch of unilateral hallucinations is contributed by Dr. Regis. Dr. Chambard describes an extremely rare form of cerebral tumour—primitive epithelial carcinoma of the pia mater. Dr. Boye gives an account of the results obtained in the practice of M. Ball by the not altogether new method of combining familiar drugs in the treatment of epilepsy. A few abstracts, a series of clinical cases, analyses of the proceedings of the scientific societies, and some reviews conclude the number.

Pheasants; their Natural History and Practical Management. By W. B. Tegetmeier, F.Z.S. Second Edition, greatly enlarged. London: Horace Cox, *The Field* Office.

We are glad to notice the issue of a second edition of this beautiful work, which should be on the book-shelves of every sportsman, and is not without interest for students of natural history.

New Inventions.

A NEW SURGICAL POCKET CASE.

Messrs. Lawley & Son, 18, Farringdon-street, have submitted to our notice a new pocket case containing, in a small and tolerably portable form, all the instruments required by the student, surgeon, or general practitioner, for the performance of most minor operations and a few of the larger operations. The case contains several knives, scalpel, bistouries, lancets, and a small saw with movable handles, a director and ear scoop, a caustic holder, thermometer, male and female catheter, hypodermic syringe and bottle, probes, spatula, scissors, dressing, artery, and polypus forceps, a grooved needle, and other instruments. Indeed there are too many articles rather than too few. The absence of a fine trocar and cannula may easily be corrected. The arrangement is ingenious and the total cost comparatively small.

ABDOMINAL BELT.

Dr. Fisher's abdominal belt may be worn for support during pregnancy or with a pad for umbilical hernia. The advantages claimed for it are that it is cut in parts so as to fit the figure, and that it contains neither elastic nor whalebone.

FLESH RUBBERS FOR THE BATH.

Messrs. F. Newbery & Sons, of London, have submitted some specimens of Livermore's flesh-gloves and back rubbers for use in the bath. They are made in a peculiar way with india-rubber, and answer the purpose for which they are intended exceedingly well. One great advantage is that they take the soap and make a good lather.

INTERNATIONAL MEDICAL CONGRESS.

As the time of the meeting approaches the evidence of general interest in the Congress becomes increasingly apparent. In several of the sections the number of communications already promised is large enough to fill up the entire time likely to be at their disposal, and these by contributors whose high scientific character is sufficient guarantee for the merit of their intended papers. The choice of the Executive Committee of a representative of French medical science to give the fourth of the general addresses has fallen upon Dr. Maurice Raynaud, a distinguished physician and an accomplished orator, the author of "Le Médecine au Temps de Molière," as well as more strictly scientific works of high merit. In Paris a lively interest is taken in all that pertains to the Congress by a large number of the hospital physicians and surgeons, and a number of medical men from the provincial French towns and schools have expressed their intention to be present. The College of Surgeons have decided to give a conversazione in the Hunterian Museum on Friday, August 5th, and the preparations that are being made both in respect to public and private hospitality will not be unworthy of the occasion. The Society of Apothecaries of London have liberally granted the sum of £52 10*s.* to the funds of the Congress, and the College of Surgeons of Ireland the sum of £25; and it is hoped that all intending subscribers to the Congress will signify the amount they wish to give as soon as possible, as otherwise the Executive and Reception Committees are unable to finally decide upon the programme of entertainments, the cost of which for so large a number as that which is expected being necessarily large.

Mr. Whitfield Perkins, upon recently resigning the appointment of Assistant Medical Officer to the City of London Lunatic Asylum, Stone, near Dartford, Kent, was presented with many gratifying tokens of esteem by the officers and employés of the institution, including a pony carriage, a tea-pot, a coffee-pot, &c., subscribed for by the attendants and artisans.

THE LANCET.

LONDON: SATURDAY, APRIL 9, 1881.

WIDESPREAD astonishment and unfeigned regret have been occasioned by the announcement that Dr. QUAIN, an eminent physician of the orthodox school of scientific medicine, has been called in consultation at the bedside of the Earl of BEACONSFIELD, and consented to meet and act with Dr. KIDD, a reputed homœopath. The explanation offered is that Dr. KIDD had not been treating the noble lord on homœopathic principles, but "according to the regular practice of allopathy," whatever that may mean; and Dr. QUAIN, though he at first declined, having satisfied himself on this point, and taken the advice of "leading members" of the profession, was able to lay aside his scruples, and even to persuade himself that he "would not, under the circumstances, be justified in persisting in his refusal." The question which first suggests itself on receiving this account of the matter will probably be, *Who* are the "leading members" of the profession upon whose counsel Dr. QUAIN acted? It is not a little remarkable that no recent scandal has occurred, or mistake has been committed by any prominent member of the profession, without a similar expression of opinion from some unknown or unrecognised "authority," lending countenance and giving approval to the wrong done.

Who are the "leading members," the unseen censors of professional conduct and policy, whose advice in moments of difficulty proves so strangely at variance with the feeling and judgment of the great body of their brethren? It is time these mysterious counsellors should declare themselves; and, in the name of the profession, we now ask them to accept the responsibility, and if they can, to offer a satisfactory explanation of the counsel they have given, and the course they have approved. The next question will be, What sort of notion can the two physicians acting together in the case of the Earl of BEACONSFIELD have formed of the obligations which rest on every practitioner? They are both men of high reputation and acknowledged ability in their respective spheres of professional life. Nothing therefore which we may feel bound to advance in the frank discussion of this question can be held to have personal motive or incidence. The issue raised is not in any sense personal. The question is one of *principle*, not of men. Having made this clear, we repeat, What notion of professional responsibility can the practitioners thus unaccountably acting together seriously entertain?

There are three professions in the practice of which submission to the will or whim of an employer is impossible. The lawyer cannot construe an Act of Parliament in accordance with the views of his client, or, if he does, it is with the knowledge that his private interpretation will be set aside by any court of law which may be called upon to adjudicate. The divine may not so stultify the first principles of religion, as to adapt the doctrine he preaches to the desires or predilections of his congregation. It is equally impossible for the medical practitioner to submit his scientific judgment of the laws of health and disease, the principles and methods of treatment, to the whim or the prejudices of his patient. The physician who will undertake to treat the sick on either of two systems which are contradictory and mutually destructive is like the preacher who should offer his hearers a choice between the dogmas of Christianity and Mohammedanism, and agree to speak as the prophet of either indifferently.

If homœopathy be a *true* system of medicine, the regular system — which the homœopath stigmatises as "allopathy" — must be false. It is obvious, therefore, that a physician who is willing to practise either of these systems at the bidding of the sick person who seeks his services or on his own eclectic judgment, cannot be acting under a due sense of the importance of the work in which he is engaged. Consistent homœopathists will hold with us in this contention, and they will concede that it is only on the presumption of earnestness in our several divergent beliefs that we can agree to differ with anything like mutual respect. The "homœopath" who can reconcile it with his own conscience to practise what he calls "allopathy" when occasion offers — who, in short, is ready to become all things to all patients that he may win some— can be no true disciple of HAHNEMANN, who, as we pointed out in March, 1875, in connexion with a question arising at the Birmingham Midland Institute, insisted that homœopathy "must be *exclusive*," and that "all backward straying to the pernicious practice of the old school (whose opposite it is as day is to night) is totally impossible." And the practitioner of the regular school who is willing to aid and abet the errant homœopath in his excursions into the province of what we term orthodox medicine, cannot but be regarded by us as a paradox. The position occupied by Dr. KIDD is as strange as it must be unsatisfactory to members of the school with which he is most closely identified. The position taken up by Dr. QUAIN in this matter is at once inexplicable and embarrassing.

It is impossible to regard the consultations which have taken place, between two gentlemen representing antagonistic schools of thought, in the light of serious endeavours to arrive by scientific deliberation at a concerted judgment on the state of their distinguished patient, and the measures to be taken for his relief. One at least of the two must have been lukewarm in his allegiance to the principle on which he had consented to act in the treatment of this particular case, while the other could not fail to feel that he was working with a physician who belonged to a school whose every tenet is opposed to the principles of that which he claims to represent. What could the two men thus thrown together have in common? On what premisses can their argument have been based? The issues at stake were not of a nature to be jeopardised by any lack of concord or earnestness. Life and death may have been in the balance. How should these two physicians work together except they be agreed? Every practitioner must feel that what he does for his patient is to the full extent of his knowledge or belief the best that can be done, or he must defer to the judgment of a colleague in whose scientific attainments and clinical experience he has the utmost confidence. The status of the doctor and the rank of the patient cannot affect the issue raised. The *bona fides* of the consultants may not be called in question, but the considerations we urge are of the highest gravity, and they cannot either be gainsaid or lightly set aside.

The more strictly professional bearings of the case are not less disturbing. It has a painful interest for every practising member of the body to which we belong. If when the physicians concerned in a matter of this class are men of eminence, and the patient is a distinguished personage, rules of etiquette may be ruthlessly transgressed, it is idle to expect that these rules will be held binding upon practitioners of less note in regard to their ordinary *clientèle*. If homœopaths may at pleasure treat their patients "according to the regular practice of allopathy," and, *when* they do this, regular practitioners are at liberty to consult and act with them, this should be generally understood. It has hitherto been a custom of professional ethics that no sort of intercourse can be held with homœopaths, even when these gentlemen, in defiance of the rule laid down by their master, elect to practise "the old system." The fact that they for the nonce, or for some passing purpose, choose to pose as orthodox, has not been held to condone their error, or render them trustworthy associates for the scientific practitioner. If we are henceforth to recognise a Dutch-clock mode of practice this, we say, should be understood. The effect of such an understanding must, of course, be to foster the development of a class of men who will degrade the art of healing to the level of a service done "to please"; but if this effacement of scientific medicine is to be accomplished with the consent of "leading members" of the profession, common justice requires that the feasibility of such a concession shall be publicly announced and generally recognised. We cannot heap reproaches on the head of some struggling practitioner in an obscure district because he consorts with homœopaths acting or pretending to act "allopathically," while an eminent physician does precisely the same thing with the sanction of his esteemed and trusted brethren in London. The profession, as a whole, has a right to demand that "men of light and leading" shall be at least as punctilious in their own observance of the rules laid down for professional guidance as they expect average members of the medical body to be. We must be absolutely just, without respect of persons, either of physicians or their patients. Let it be settled once for all that there is a single code of ethics applicable to all classes of practitioners and governing their relations with patients, whether these be peers or peasants. It has hitherto been the boast of the medical profession that in the hour of sickness it recognised only humanity in need of succour. It will be a dark day for scientific medicine when this claim to independence and impartiality is waived, and the conduct of professors of the healing art towards each other and towards those who seek their aid comes to vary with the rank the physician and patient may chance to occupy.

Whether we look at this question from the public or the professional standpoint, it must be plainly seen to be one of grave import. There is, unhappily, no appeal except to the general judgment of the profession. The Royal College of Physicians has only too conclusively proved that it cannot be trusted with the decision of questions affecting the *morale* of the profession. If any expression of opinion were extorted from the feeble-minded corporation in Pall-mall, it would be either a condonation of the error into which a distinguished Fellow has fallen, or a stringing together of platitudes with which no sensible practitioner could have any reasonable concern. The profession must decide the question for itself, and in so doing we are persuaded it will be guided solely by the interests of right and fairness. The considerations we submit are, briefly, three. First, that a due sense of the responsibility which rests on every practitioner of medicine to treat his patient on principles in which he has faith and which he honestly believes to be principles of true art, must render it impossible to practise antagonistic and mutually destructive systems of medicine alternatively or indifferently. Secondly, that only men who are agreed and see together as to the fundamental principles of disease and its treatment can consult or act in concert. Third, that the rules which govern the professional conduct of practitioners among themselves and towards their patients must be absolute and apply with equal force to all ranks of the profession and of society. If these propositions are accepted by the judgment of the medical profession, it is easy to see what the decision in this case must be. Dr. QUAIN has violated a fundamental principle of professional conduct in acting with Dr. KIDD, an eminent homœopath, in treating the Earl of BEACONSFIELD "according to the regular practice of allopathy." This is the conclusion which is forced upon us, and it is one in which we believe the profession will feel compelled to acquiesce.

◆

IT is acknowledged to be somewhat of a hardship that the Universities of England do so little to facilitate and encourage graduation in medicine. Nobody who has the reputation of the medical profession at heart wishes to see graduation made too easy. A Doctorate in Medicine ought to mean something more than a common minimum qualification. It may be said that it has not always this significance, and it would not be inaccurate to say so. But there never was a time when it was so little fair or accurate, so to speak. A degree which does not imply some superiority in education or some additional severity in examination, is something very objectionable, and calling loudly for a remedy. But the remedy is not the degradation of the process by which the title of Doctor of Medicine is procured, but the improvement of it. And to do the British Universities justice, they are more alive to the responsibility of their degree-granting function than they have ever been before. Their degrees imply more, and are more difficult to attain, than in any comparatively recent time. In fact, the difficulty of obtaining English degrees in medicine is a ground of complaint. Degrees seem to be regarded by the Universities with rather too much reverence, as something to be reserved for transcendental philosophers and scholars rather than for men who devote their lives to the rough conflict with disease and death. Such is the impracticability of the conditions on which degrees are granted in England, that for the most part English practitioners have either to go without them, or to go to Scotland or Ireland or to foreign countries for them. This grievance is set forth very ably in a pamphlet with which we have been favoured, by JOHN EDWARD MORGAN, M.D. Oxon., and Professor of Medicine at the Victoria University, Manchester—a statement so able and suggestive that no part of it is indefensible except the apology with which it is introduced. Dr. MORGAN'S question is, Why are there no medical degrees? He shows that in Scotland there are 1889 medical men to whom the Scotch Universities have granted 1207 degrees; in other words, 63 out of every 100 Scotch practitioners have obtained Scotch degrees. In Ireland there are about 3398 medical practitioners, 930 of whom, or 30 per cent., have obtained degrees, chiefly Irish; while in England there are 14,102 medical men, of whom 717, or about 5 per cent., only hold English degrees. This is a very striking statement, and the more it is studied the more worthy of attention it will appear. It is undeniable that the possession of a degree is more or less of an advantage to a practitioner. It carries weight with the public, and is an indispensable condition of holding many medical appointments; yet in England it is very difficult to obtain one. The London University is not a teaching university as the Scotch and Irish universities are, and the teaching universities of England have hitherto shown little sympathy with, or aptitude for, teaching medicine. Dr. MORGAN, though an Oxford graduate, is justly severe on the English universities, and their "gross neglect" to consider the requirements of the medical profession, while heaping favours and degrees on those intended for other professions. Thus we find that during a long period of time Oxford and Cambridge have annually dispensed some 800 or 900 degrees to Bachelors of Arts, but on an average not more than seven or eight of those degrees are bestowed on students of medicine. Dr. MORGAN finds explanations of the neglect of medicine in the whole genius and arrangements of the old universities. The short terms and the long vacations are not adapted to the grave and arduous studies of medicine. Then he points out that the old universities are ill adapted as places for the study of practical medicine, though, with good teachers and liberal prizes for medical work and investigation, we think that much more could be done than is done in this way. Durham, though associated with the Newcastle School of Medicine, which has the advantage of an enormous field for medical and surgical study, has not yet devised means for conferring degrees on any considerable number of persons. Under these circumstances, Dr. MORGAN complains bitterly that the charter of the Victoria University does not confer the power of granting medical degrees. Medicine was included in its original scope, but it was withdrawn in deference to the strong opposition of those who feared to add another to the many competing licensing bodies. This fear was not unnatural in the present state of the law; but with an improved state of the law, with a reformed Medical Council having real powers, with a consolidation of the examining bodies, it should be easy both to stir the old universities into life and action, and to give to a young and promising university power, under strict conditions, to confer degrees in Medicine. Dr. MORGAN contends, too, that the character of the London University should be enlarged; that instead of a mere examining body it should become a teaching one, and make some contribution to that education of medical men which more than mere examination goes to fit members of the medical profession for that high position in society to which, according to Dr. MORGAN, they are destined as States become wiser.

◆

THE pathological relations of diphtheria and the discovery of a micrococcal organism in the false membrane have made it almost certain that the morbid poison which gives rise to the disease is a parasitic organism. The observations to which we lately called attention that bacilli were to be found during life in the urine of patients suffering from the disease, and after death in the kidneys, constitute another step in the demonstration. From a communication to the Paris Société Anatomique we learn that a French "interne,' M. TALAMON, has succeeded in cultivating the organisms from eight cases. In the condition of complete development they presented a characteristic mycelium and spores. The former are tubes with partitions, at intervals, from two to five thousandths of a millimetre in length. These, under favourable circumstances, elongate and bifurcate, the bifurcations being characteristic in consequence of their incurved branches, like the sides of a lyre. In other conditions the mycelia do not become elongated, although they multiply so as rapidly to cover the surface of the cultivation liquid; they remain short and assume irregular forms, and give rise to numerous straight rods. The spores are of two kinds, round or oval, which may be termed the spores of germination, and rectangular spores or conidia. The latter characterise the species. They form small rectangles of various sizes, their length being sometimes fifteen thousandths of a millimetre. They may be isolated or united in festoons or zigzag chains. At first homogeneous, they soon become filled with small round granules, highly refracting, and of the size of ordinary micrococci. The round or oval spores are those which, by their elongation, constitute the mycelium. They appear as clear points, from three to five thousandths of a millimetre in diameter, in the middle of a mass of granular material. M. TALAMON has inoculated this organism into the mucous membrane of the mouth or nose, or has given it with the food, in six rabbits, two guinea-pigs, four frogs, a fowl, and four pigeons. The rabbits died at the end of six, eight, ten, and eighteen days. That which died soonest presented an enormous swelling of the neck resembling the œdema of the neck in diphtheria, and due to a serous infiltration of the connective tissue, and the culture of this serosity showed the same organism with the characteristic conidia. The rabbit which died at the end of eighteen days presented a bilateral fibrinous pleurisy, with effusion. The effusion and pleuritic membrane also yielded, on culture, the organism which had been inoculated; and it could be recognised, either by simple microscopical examination or by culture, in most cases in the liquid contained in the pericardial and peritoneal cavities, and often in the kidneys. The organism was never obtained by cultivation of the blood contained in the heart. The liquid either remained clear or presented only ordinary bacteria. In the four pigeons M. TALAMON succeeded in producing characteristic false membranes. He first scratched the mucous membrane of the mouth with a bistoury, and then placed some of the cultivated organism in the interior of the mouth. At the end of twenty-four hours a thick membrane lined both sides of the mouth, the tongue, the false palate, and the back of the pharynx. It was yellowish-white in colour, and was formed, like the diphtheritic membrane in man, by epithelial cells, fat, micrococci, and bacteria. There were very few of the rectangular conidia, but these were abundantly obtained from the membrane by cultivation. Two of the pigeons died at the end of three days. In one the entrance to the larynx was covered by false membranes, and the trachea was full of a thick mucus from which the organism was obtained by cultivation, as also from the pericardial and peritoneal liquids, but not from the blood. The third pigeon remained ill for eight days, and then the false membranes became separated and the animal recovered. At this point, unfortunately, the experiments have been for the present arrested. They were carried on in the laboratory of the Hôtel Dieu, and some of the physicians, fearing lest some of the organisms might contaminate their patients, stopped the observations. We are promised a resumption of the inquiry at an early period. The facts ascertained are of the greatest importance, and seem to open out an entirely new field of investigation as to the etiology of the disease, since M. TALAMON hints that he possesses a clue as to the source from which the organism is derived in the case of human infection.

◆

THE Report of the Medical Officer of the Local Government Board for the year 1879 has just been issued from the Parliamentary press. The delay in appearance we apprehend must be attributed to the illness and retirement of Dr. SEATON, the changes in the Medical Department rendered necessary by this event having no doubt temporarily disturbed the usual course of its proceedings. The report of the present Medical Officer opens with a graceful expression of regret offered on the part of the "immediate colleagues" of Dr. SEATON at his loss from the Department—a regret presently heightened by his death, which quickly followed upon retirement. Perhaps no subject connected with preventive medicine has been so largely before the public during the past ten years as vaccination, and certainly since the days of JENNER no man has done so much to promote vaccination in this kingdom as EDWARD CATOR SEATON; yet he passed to the grave without any honourable recognition by the Government whom he had so long and faithfully served, and wellnigh unnoticed by the public, who benefited so largely by his great services to them, and who while he was dying were loudly proclaiming the benefits they had derived from him, heedless of the benefactor. "O stormy peple, unsad and ever untrewe," as CHAUCER hath it. In consequence of the delay in the appearance of the report much of the contents of the volume have necessarily been anticipated. Thus, Mr. POWER'S report on an outbreak of "fever" that proved to be of the nature of trichiniasis on board the Reformatory School ship *Cornwall*, Dr. THORNE THORNE'S report of an extensive epidemic of enteric fever at Red Hill, Caterham, and other adjoining places, Dr. AIRY'S report on an outbreak of scarlatina at Fallowfield, near Manchester, and the report by a Committee of the Pathological Society of London on the infective diseases known as pyæmia, septicæmia, and purulent infection, an inquiry carried out by the Society under an engagement entered into with the Local Government Board, all are reproduced in this volume, but all were published separately at the time they were made and were dealt with in the columns of THE LANCET. Mr. POWER'S report, however, obtains a new interest as it appears here. At the time when the report first appeared doubts were entertained as to the precise nature of the nematoid parasite which he had found in the body of the sole patient who had died from the supposed "enteric fever" on board the *Cornwall*. It now appears that this question was submitted to Dr. CHARLTON BASTIAN, F.R.S., and Mr. POWER'S report is followed by one from this gentleman, showing that the nematoid discovered belonged to the Anguillulidæ, genus *Pelodera*, and he has named it *Pelodera setigera*. This determination adds a new and greater interest to Mr. POWER'S report, and Dr. BASTIAN offers some observations on the subject of great value. Of the new matter in the volume we may note a report of series of a careful observations on the results of vaccination by Dr. CORY with animal lymph obtained from Dr. WARLOMONT, of Brussels, and of which Dr. BUCHANAN says: "That in some respects they differed from those which he habitually obtains with long-humanised lymph; that there was no reason for preferring the results of the calf lymph; and that the humanised lymph had, in its arm-to-arm transmissions, the advantage over the calf lymph of showing greater uniformity of action." Other new matter is found in reports by Dr. KLEIN on the lymphatic system of the skin and mucous membrane, and on the results of certain experiments made by him on the inoculation of bovine animals with small-pox; and a continuation of Dr. THUDICHUM'S researches on the chemical constitution of the brain, in view of the determination of some questions in the chemical pathology of that organ. Dr. BUCHANAN, in his own report as Medical Officer, offers brief but suggestive comments on these reports, and details equally briefly the general proceedings of the Medical Department during the year to which the report refers. The brevity of his observations gives rise, indeed, to the main point of criticism to which his report is open. The suggestiveness of several of his observations gives us a desire to have more from him, and we should be disposed to complain were it not that we have in remembrance that it was just in this somewhat abruptedly curtailed fashion of annotation, as it were, that JOHN SIMON commenced the famous series of reports of which this forms a continuation. We are inclined, therefore, to regard this brevity, however much we may regret it for the moment, as a good augury for the future, and to buoy ourselves up with the belief that it is merely the indication of a mental habit which will bear fruit in the future not less famous than that which characterised the reports of the first holder of the office which Dr. BUCHANAN now fills.

◆

THE question of competitive examinations for public appointments is one which deserves the serious consideration of all who are interested in the welfare of the young. It is no doubt a matter of importance that the appointments in our public offices and in our Army and Navy should be filled by well-educated young men competent to discharge the duties, physical and mental, which devolve upon them, and likely to remain efficient in both respects for a reasonable period, unforeseen accidents excepted. To ensure these conditions it appears requisite that they should have been well taught those branches of knowledge which are required of them, and that their education should have been so conducted as not to have injured their bodily health or overstrained their mental powers in the preparation for the competition on which their subsequent career may depend. We greatly fear that these indispensable conditions are too often lost sight of by the authorities on whom rests the responsibility of conducting the examinations, and that, as a result, youths come up crammed but not educated, and with constitutions often seriously damaged by overwork. Young men entering the service under such conditions are not likely to prove efficient for any length of time, either mentally or physically. The knowledge—if it deserves that name—which has been driven into them by the crammer is too often lost with even greater rapidity than it has been acquired, and the remembrance of what they have gone through gives them a distaste for mental work which prevents any exertion in the direction of self-education. A clerk under such circumstances degenerates into a bad copying machine; while an officer in the Army or Navy turns out a useless encumbrance, not to be relied on in an emergency. We are far from saying that this is applicable to all who go successfully through a competitive examination, for we have known very many who have entered the public service as a result of preparation honestly made, and in whom the effects of such a course were manifest throughout their subsequent careers. But we cannot disguise the fact that there is a large amount of very unsatisfactory work, the outcome of which is injurious alike to the public and to the successful competitor. We have been led to make these remarks by the receipt of a Parliamentary paper entitled "Regulations respecting Naval Cadets." In future, appointments to naval cadetships are to be made by limited competition. The candidate must not be less than twelve nor more than thirteen and a half years of age, and must be found physically fit for the Navy by a medical examiner. Let us now see what he is required to know in order that he may be entered for training on board the *Britannia*. In the preliminary examination are comprised—arithmetic, including proportion, vulgar and decimal fractions; algebra, including fractions and simple equations with one unknown quantity; geometry—definitions, postulates, axioms, and subjects of the first twenty-six propositions of Euclid's Elements; English—writing from dictation, reading with intelligence, and parsing easy sentences; French—translating, by aid of a dictionary, French into English, and English into French, reading, parsing, and speaking; Scripture history. If the boy is successful in passing this examination—and to do so he must obtain at least four-tenths of the marks assigned to each subject,—he is then examined on any two he may select of the following subjects: elementary mathematics; miscellaneous questions in arithmetic, algebra, including quadratic equations, and geometry to the end of the first book of Euclid's Elements; Latin—reading, parsing, and translating, by aid of a dictionary, Latin into English, and English into Latin; geography and English history, outlines. We should like to know the opinion of any good master, accustomed to boys of that age, as to the probability of their really having acquired such a knowledge of these subjects as they would be likely to retain, and turn to use in their subsequent career. We entertain strong doubts of their ability to do so, and feel satisfied that many boys must break down in the attempt. It is intended that so many candidates shall be nominated that not more than one-third of those examined will be entered. Now, we would ask, is it fair to the boys to require them to work up for such an examination with the certainty that two-thirds of them must fail to obtain the object of their labour? Is it just to their parents to put them to the expense of educating their boys for a special profession with such odds against them being permitted to follow it? Is it humane to make the subjects of a competitive examination so much above the ordinary capacity of boys at that age as to render it probable that many of them may break down in preparing for it, and receive no compensation for perhaps a lifelong injury? The authorities appear either to have forgotten the age of the candidates in laying down the subjects for examination, or to have made it unduly severe to deter numbers of otherwise eligible boys from endeavouring to enter the service. We sincerely trust that the Lords of the Admiralty will reconsider the whole matter, and adopt a standard of qualification for admission more suited to the physical capabilities of boys. Mr. BRASSEY knows what the requirements of the service are, and we trust he will, from motives alike of fair play and humanity, take up the subject with a view to placing the whole question on a more reasonable footing in the interests equally of the Navy and of the ambitious youngsters who long to adopt it as their career.

Annotations.

"Ne quid nimis."

THE ROYAL COMMISSION ON THE MEDICAL ACTS.

WE have good reason to believe that our arguments have prevailed, and that the Government has abandoned the idea of a Commission on Medical Acts in which medical men should be conspicuous by their absence. Having determined to include medical men, it is next most important that the selection should be such as to elicit the truth as to the existing bodies which regulate the medical education and conduct the medical examinations of the country. The medical men to be chosen should be such as to represent not merely the Medical Council and the medical corporations, but the general body of the profession, who are most familiar with the wants of the public and with the existing defects in medical legislation. It would not be fair to medical men favourable to reasonable changes either to leave them out or put them in a minority—as against the champions of existing arrangements. We have throughout believed in the earnestness of the Government in this matter, and our faith serves us still. We look confidently to a Commission so composed as to command the respect of the medical profession and of the public.

MYOPIA IN SCHOOLS.

THOUGH it is desirable that public attention should now and then be directed to questions of the hygiene of vision, it is hard to believe that the risks and dangers, as well as the alleged frequency of grave ocular defects, have not been somewhat exaggerated. Awhile ago the schoolmaster was sent abroad, rod in hand; now it is the oculist that is playing the part of "bogey." The public have barely recovered from the scare of the perils to which they are alleged to be exposed in consequence of the prevalence of colour-blindness among engine-drivers, signalmen, pilots, and others, before they are startled by the information that our public schools "are manufacturing a race of shortsighted people." There may be, and doubtless is, some modicum of truth in this opinion recently given by an ophthalmic surgeon respecting the boys at Wellington College; but the statement that the public schools are manufacturing a race of myopes is not true to anything like the same extent as that matrimony is doing so. Myopia, and the tendency to myopia, are usually inherited, and it is not an uncommon thing to find a large family of children all inheriting myopia from one parent; but few persons would on this account alone recommend universal and perpetual celibacy. Myopia may, no doubt, be developed, and the tendency to myopia may be aggravated by neglect of the known physiological conditions of healthy vision, and it is therefore incumbent upon all persons concerned in the construction of school buildings, and upon those who have charge of the education of children and youths, to take care that these conditions are strictly observed. As regards our public schools and universities, however, it should not be forgotten that shortsightedness is a fashionable complaint. Myopia has been said to be an affection of those who read much and think little; it fairly belongs, therefore, to the present age.

CONTINUED ILLNESS OF THE EARL OF BEACONSFIELD.

THE Earl of Beaconsfield has, during the week, passed through a series of sudden and seemingly critical changes of condition. The gout has been, from time to time, apparently localised, and the bronchitic symptoms have been temporarily relieved; but the periods of respite have not been long, although they have, doubtless, afforded the system an opportunity to recover itself after each attack, so that, on the whole, the strength of the sufferer has been maintained. A very serious paroxysm of the associated congestion and spasm occurred in the early morning of Thursday, and the danger to life appeared so imminent that, at the personal request of Dr. Quain, Sir William Jenner visited Lord Beaconsfield. It is needless to say that Sir William simply acted in the emergency with Dr. Quain *only*, and did not take part in any general consultation. It is difficult at the time when we write to add much to the statement made last week; but considering the length of the illness, and looking to the fact that the severity of the attacks does not abate, the out-look cannot but be regarded as more than commonly threatening. At the same time it is a favourable feature in the case that the noble lord has taken a fair amount of nourishment, and in the intervals of his more urgent sufferings exhibited considerable cheerfulness. The discouraging circumstance in the clinical aspect of the case is the non-development of the local disease, and consequent perpetual dispersion of the poison throughout the system. It is now, moreover, late in the progress of the case to hope for relief from localisation! The strength of the patient is seriously exhausted. Meanwhile we would cherish the maximum of reasonable hope.

AN APOLOGY FOR THE OPIUM TRADE.

DEPUTY SURGEON-GENERAL W. J. MOORE discusses at some length the opium question, with particular reference to the case of China and our trade, in the *Indian Medical Gazette* of September and October respectively. The papers are very interesting and contain a good deal of information. The author regards the use of opium in China and other countries as very comparable to the use of alcohol in this country. He is disposed to extenuate its injuriousness and to magnify its uses. The Chinese take it, almost need it, he argues, on account of their poverty. It reduces waste of tissue, and it gives a more pleasant aspect to a life of monotony and poverty. In excess it is undoubtedly injurious, and may merit the strong censure that philanthropists have indulged in, but "it is not more injurious than alcohol in excess," and opium taken in moderation is not injurious. Seeing that the Chinese will have opium, they had better have the better sorts that we supply from India than the worse native forms of it. There is no stronger moral reason for opposing the opium trade than the trade in alcohol. The fact that some Chinese "take opium in excess is no moral reason why trade should be restricted further than by the imposition of Custom dues." The *tu quoque* retort upon all European philanthropy in regard to this question is, we think, rather too strongly used. We do not desire to be narrow or too austere in our views, but we scarcely see the necessity for medical men to become the apologists of such customs as the use of opium. If it be true that it is made necessary by the social condition of the people, so much the worse for the social condition. It is not worse as a national habit than the use of alcohol by European nations—which we very much question—even then two blacks do not make one white. It is only fair too to British philanthropists to say that those who oppose the opium trade oppose the alcohol trade. An enormous amount of quiet scientific opinion is expressed against our national use of alcohol, which is telling slowly upon sensible people in all ranks of life. But we may still have a word to say against the use of opium by other nations. The duty of medicine, as we take it, is not to find apologies for the bad habits of nations, but to try to bring national habits into conformity with the laws of health. The opium trade is another question, and it has two sides, but, from our point of view, we cannot recommend even a poor Chinaman to begin the use of opium in the hope that he will do it moderately. It is not likely either to lessen his poverty or assuage his misery.

SYPHILIS AND LOCOMOTOR ATAXY.

IN a communication to a recent number of the *Centralblatt für Med. Wissenschaften*, Erb has published an additional and important series of facts regarding the relation of syphilis to locomotor ataxy. They are in perfect agreement with the results which he has previously published, and with those brought forward by Dr. Gowers in our columns (THE LANCET, January 15th, p. 94). Of one hundred consecutive cases of tabes, only twelve gave no history of a chancre or secondary symptoms. In fifty-nine there was a history of secondary syphilis, and in twenty-nine of a chancre without secondary symptoms, making a total of eighty-eight in which there was either a venereal sore or constitutional syphilis. Of the twenty-nine cases with a chancre only, eleven were known to have been so treated (with mercury or iodide) as to make it probable that the sore was a hard one. The interval between the primary sore and the first symptoms of the ataxy was ascertained in eighty-eight cases, and it was between three and five years in seventeen cases, between six and ten years in thirty-seven cases, between eleven and twenty years in twenty-four cases, and more than twenty years in ten cases. In order to ascertain the truth of the objection that the large percentage of cases of ataxy with preceding venereal sores or constitutional syphilis is due simply to the commonness of the latter, Erb has investigated the history of four hundred individuals over twenty-five years of age, who were under treatment for diseases which were not suspected to have any relation to syphilis. The percentages of each hundred agreed very closely, and that for the whole four hundred was—a history of a chancre only, 11 per cent.; a history of secondary syphilis, 12 per cent.; and no history of either chancre or constitutional syphilis in 77 per cent. Thus, 23 per cent. had had a chancre or constitutional syphilis, while among the ataxic patients taken from the same social classes the proportion was no less than 88 per cent. Erb concludes that these figures justify the assumption that there must be an etiological connexion between syphilis and locomotor ataxy.

THE DEADLY EAST WIND.

FROM the earliest times the east wind has been proverbially stigmatised as inimical to life in all its forms, and generally disastrous in the influence it exerts on living organisms. Authorities differ as to the precise cause of its destructive properties; but all agree in describing the wind as peculiarly acrid and withering. It is dry itself, and seems to extract the moisture from every tissue with which it comes in contact. Of all winds, that which blows from the east is the most likely to check the insensible perspiration, to chill the surface, and to produce "cold." It is even possible the wind may be laden with germs which produce a specific effect on the lining membranes of the air-passages. However that may be, there is the strongest reason to believe that the terminal filaments of the nerves distributed in the skin are mechanically compressed by the contraction occasioned by this "eager and nipping air." Those who are well able to resist the onslaught of other winds cower before the east, while the sick grow worse while it blows, or are unable to rally in such a way as to shake off the incubus of disease. In respect to no inclemency of the weather is it more necessary to fortify the body, through the mind acting indirectly through the nervous system, than this common enemy from the east. To give way to mental depression in the struggle is to yield ground. The man who fears that he will "take cold" is almost sure to do so. Conversely, a "good heart" is as trusty a protection as a warm "comforter"; albeit, no one should scruple to have recourse to extra clothing while the wind blows from the east, and particularly when it remains long in that quarter. Few but the most sturdy can hold out against a prolonged assault.

MR. WHARTON JONES, F.R.S.

THE profession will learn with regret that Mr. Wharton Jones has retired from his connexion with University College and Hospital as Professor of Ophthalmic Medicine and Surgery, and as Ophthalmic Surgeon, respectively. The connexion thus severed has extended over thirty years, and covers the student life of several generations of medical practitioners. Those who cherish an affectionate and respectful remembrance of the days when the name of this distinguished ophthalmologist was a household word throughout the schools of the United Kingdom and on the Continent, cannot yield to their juniors in the esteem which is felt for Mr. Wharton Jones. We trust that, though the fulness of years and that natural yearning for rest which comes in the autumn of a busy life, have compelled this retirement from collegiate and hospital work, Mr. Wharton Jones may long be spared to use his ripe knowledge and experience for the advantage of the profession and the public.

MISSED LABOUR.

AT the March meeting of the Obstetrical Society a paper was read by Dr. Barnes on Missed Labour, in which the author entered exhaustively into the subject. Full details of a case which had occurred under the observation of Dr. Barnes himself were given, and in which gestation had been greatly prolonged. The discussion upon it was adjourned till last Wednesday. Such cases have a pathological as well as medico-legal interest, for the possibility of the retention of the fœtus within the body of the mother for months or years after the full period of gestation has elapsed has bearings of the greatest importance from a social point of view. Though such occurrences are rare, yet there are several such cases on record, the genuineness of which cannot be doubted; and the possibility of the accident—for such it must be regarded—is beyond dispute. It happens, however, it appears, only when the fœtus is dead. In the recorded cases there appears to be usually a history of some accident or injury, and upon this fact, together with the observations made post mortem, Dr. Roper based an ingenious theory—namely, that cases of missed labour are cases in which rupture of the uterus had taken place and the child had escaped through the rent into the surrounding tissues or abdominal cavity. In the case observed by Dr. Barnes, he seems to have convinced himself that the fœtus was in the cavity of the uterus by the introduction of the hand into that cavity; but though such an observation made by such an observer is of the greatest value, it cannot take the place of examination after death. The theory of Dr. Roper is not incompatible with Dr. Barnes's observation, and the question cannot be settled but by careful post-mortem investigation.

DR. ACLAND ON ALCOHOL.

DR. ACLAND, at the special request of the Oxford Ladies' Diocesan Branch of the Church of England Temperance Society, lately delivered an address at the residence of the warden of Keble College, on the invitation of the Hon. Mrs. Talbot. Dr. Acland presented to his audience one aspect of the pathological argument against the excessive or frequent use of alcohol. He was on firm ground in charging alcohol with the frequent causation of cirrhosis, especially in the form of spirits, and *à fortiori* when these are taken neat and without food. Of the thirty-six patients that Frerichs observed suffering from cirrhosis, twelve confessed to drinking brandy in excess, and several others were suspected. It is only fair, however, to say, in Frerichs' own words, that in a large number of cases it would not be right to attribute the disease to abuse of spirits. In some of these cases it is quite possible that a tendency to the disease has been inherited. Dr. Acland did not tell his fair audience how far they might go in the use of "a little wine" without incurring the terrible consequences which he portrayed. Ladies, though they have taken a very creditable share in the reform of the drinking customs, have yet a lingering preference for the stronger wines, notably for a little "red port," though their sedentary lives make this a very bad wine for them. If they could be induced to take as favourable a view of light wines as physicians take, an important advance would be made in the direction of physiological temperance.

ARMY MEDICAL SCHOOL, NETLEY.

THE forty-second session of the Army Medical School was opened on the 4th inst. by Professor Aitken, F.R.S., who, in the presence of his colleagues and the staff of the Royal Victoria Hospital, gave the introductory lecture, taking for his theme the progress of medicine in the last twenty years. It is hardly necessary to say that the learned lecturer handled his subject with the fulness of knowledge and clearness of expression to be looked for from an author and teacher of his now European reputation. Forty surgeons on probation for the British Army, and twenty-two candidates for commissions in H.M. Indian Army, listened with marked attention to this instructive lecture, so well calculated to stimulate the minds of young medical officers to prepare themselves for "honourable mention" in the record of the medicine of the future. It was with much regret we noticed the absence of naval uniforms on the benches of the lecture-room at Netley. This is a mysterious subject, on which we shall only observe that, judging from the qualifications of young medical officers for the public services, as indicated by the marks both of the London and Netley examinations, no class stood more in need of a course of special instruction than the young men who of late years have entered the medical service of the Royal Navy.

INDIGNITIES OF THE CENSUS PAPER.

EITHER the actual framers of the Census forms had an original notion of the duty devolving upon them, or their instructions were extraordinary. In the direction for the enumeration of occupations the professions are thus strangely indicated :—"Physician," "Surgeon," "Dentist," "Oculist," "General Practitioner," &c. The idea of placing an "Oculist," who must by law be a qualified surgeon, below a "Dentist," who for anything known to the law may be a registered blacksmith, would be simply grotesque but that it is significant of the ignorance or error which prevails in official circles. It may be interesting to the authorities to know that the result has been that ophthalmic surgeons generally have declined to describe themselves as "oculists," and the returns will, therefore, be valueless in so far as this point of information is concerned. Like blunders have, we believe, led to similar vitiations of the Census in other respects.

A SUBSCRIPTION LIST has been opened for the purpose of perpetuating by a substantial testimonial the recollection of Mr. Frank Buckland's services to Natural History and Fish-Culture, and generally of affording to the public an opportunity of paying a tribute of respect to his memory and appreciation of his life-long work. It is intended to expend a portion of the sum subscribed upon a bust of Mr. Buckland, to be placed in the Museum at South Kensington, with the collection which he so generously bequeathed to the nation. It is further hoped that the amount collected may be sufficient to supplement the income of Mr. Buckland's widow by an annuity of £100. Should there be any surplus after the purchase of the bust and the annuity, the Committee propose that it should be applied to promoting the welfare of the fishermen of this country—an object which Mr. Frank Buckland had so much at heart. Subscriptions will be received by Messrs. Cox and Co., Bankers, Craig's-court, Charing-cross, and at 34, Portland-place, by the Hon. Secs., Mr. T. Douglas Murray, and Lieut.-Col. E. S. Bridges.

IMPERFECTION of vision in railway *employés* has formed the subject of legislation in the Massachusetts Representative Assembly, to which the Railway Committee has reported a Bill to the effect that "No railroad company shall employ any person in a position requiring the distinguishing of form or colour signals, unless such person within two years next preceding has been examined for colour-blindness and other defective sight by some competent person, and has received a certificate that he is not disqualified, by reason of any defect of vision, to perform the duties of such a position."

A SUCCESSFUL case of colotomy has been performed at Malta, in a case of malignant disease of the rectum, the operator being Surgeon-General W. A. Mackinnon, C.B., the principal medical officer of the station. We are informed that this is the first occasion on which this operation has been performed in the island.

THOSE of our readers who are contemplating a visit to Boulogne during the Easter holidays should take the precaution of being revaccinated, as small-pox is understood to be very prevalent in the French watering-place, and the authorities are, to put it mildly, not over-anxious that the fact should be known.

AN effort to amend the present mode of administering the relief which the Surgical Aid Society has to offer was, at a meeting of the committee at the City Terminus Hotel on Monday, unsuccessful. A resolution with the above object was rejected by 37 votes against 8. Still we are of opinion that, by the society's rules, a great deal of unnecessary worry and trouble is demanded of applicants, in order to obtain the help which the institution was established to afford.

AT the Royal Institution on Wednesday the Faraday Lecture was delivered by Professor Helmholtz, who took for his subject the "Modern Development of Faraday's Conception of Electricity." The discourse was, as was to be expected, a masterly exposition of the direction and scope of the discoveries and experiments of the great chemist, the admirers of whom will welcome the publication of this lecture in a complete form.

WE regret to learn of the early decease of a very promising young French surgeon, Dr. W. H. E. Gregory of Bordeaux. Dr. Gregory was of English descent, but had resided at Bordeaux all his life, and at the time of his death was *prosecteur* at the medical school of that city. He recently brought out a small work on External and Internal Urethrotomy, in which he attempted to prove the great value of the former, and the dangers of the latter, operation.

A SPECIAL meeting of the Epidemiological Society will be held at University College on Wednesday, April 13th, at 8 P.M., when a paper will be read by Surgeon E. G. Russell, M.B., B.Sc., entitled "Certain Points in connexion with Malarial Fevers in India."

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL INSPECTORS OF THE LOCAL GOVERNMENT BOARD.

Diphtheria (Dr. AIRY).—In February of last year, Dr. Airy received instructions from the Local Government Board "to visit some of the subdistricts, in which it appeared, by the Registrar-General's Returns for the fourth quarter of 1879, that there had been strongly localised outbreaks of diphtheria, in order to inquire as to the behaviour of this disease among small communities." The result of this inquiry is now before us, and includes an investigation of thirteen local outbreaks of this disease in various parts of the kingdom. Although this carefully conducted investigation has led to no new light being thrown upon the malady, it has contributed a good deal to a clearer insight into questions previously debated, and has proved very suggestive of directions of further research. Dr. Airy has considered the results of the inquiry as they bear upon topography, the duration, extent, and novelty of the epidemic in the locality affected, the concurrence or recent prevalence of other diseases in the locality, the local and personal conditions predisposing to diphtheria, the communicability of the disease, &c., and on each of these subjects his observations deserve attentive consideration. He offers also certain suggestions and inferences on the origin and ultimate pathology of the disease. As to the former question, he thinks the inquiry leaves no escape from Dr. Sanderson's conclusion, "that unless it be supposed that the material cause of diphtheria is from time to time generated *de novo*, it is *capable of existing and moving from place to place independently of its subjects.*" As regards the second question he has the following observations :—"The supposition that diphtheria, in the origin of an outbreak, is caused by an organism that haunts air, or water, appears to me to conform most closely to the requirements of observed fact. It is quite reasonable to suppose that such an organism, having a subsistence dependent upon seasonal conditions, should have its own special season of maximum growth and reproductive power; that it should be capable of infecting water or milk; and that it should affect preferentially a particular character of soil, such as clay, and avoid the smoky purlieus of a town. The preference of diphtheria for dwellings in exposed and elevated situations is difficult to explain on any theory, except that of exposure to the wind and to whatever the wind may carry. (For valuable arguments and suggestions in support of this theory I would refer to Mr. A. Wynter Blyth's paper cited above.) Such facts as that of the immunity of town children attending a country school could be understood, if we suppose that the country children, taking another direction, breathed air containing an organism which the town children escaped. Possibly the 'progressive development of infectiveness' observed by Dr. Thorne at Llanrhaiadr might correspond (as Dr. Thorne has himself suggested) to progressive development of the organism towards the attainment of full reproductive power. Such an organism might be expected finally to yield itself to microscopic identification in its (supposed) native haunts."

Enteric Fever at Pemberton and Orrell (Dr. AIRY).—This report by Dr. Airy is directed to the elucidation of a serious outbreak of enteric fever at Pemberton and Orrell, in Lancashire, in the autumn of 1880. Abundant evidence was found in the state of privy nuisance, and doubtful condition of water-supply as to excremental pollution, to account for much prevalence of enteric fever in the localities; but it was found impracticable to disentangle the influences of these several sources of the disease in the production of the particular outbreak, or determine the probable mode in which the gravity of the outbreak had been brought about.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Doncaster (*Rural*), *Goole* (*Rural*), *&c.*, *Combined Districts.*—Dr. Mitchell Wilson's reports for the several sanitary districts entering into the combination for which he is medical officer of health contains much of interest. These districts include Doncaster, Goole, and Tadcaster *rural* districts; and Goole, Selby, and Tickhill *urban* districts. They contain an estimated population of over 83,000, and had in 1880 a death-rate from all causes of about 19·0 per 1000 inhabitants. Dr. Wilson has some useful remarks about the influence of *dampness* of houses upon the health of the inmates, and points out how this dampness is apt to occur in rural districts from the floors of the cottages being placed on undrained ground, from the absence of any damp-proof course in the house-walls, and from the want of any pipes to carry off rain-water from the roofs. "Landlords," he writes, "far too often look upon the latter as a convenience only useful for the tenants in collecting soft water, instead of considering the bad effect on the foundation and walls of the house." Dr. Wilson is inclined to believe from his observation of typhoid fever that it is directly infectious, or at least that direct infection plays a part in its dissemination, and he draws attention to attacks of a febrile indisposition, which were different from the ordinary attacks of typhoid fever both in point of duration and intensity, but which are observed occurring at the same time and under similar conditions as typhoid. He observes: "An interesting point in connexion with these mild febrile cases is, have the dejecta the power of conveying to other persons the infection of true enteric fever? If so, and occasional cases seem to point in that direction, they will supply the link which is so often missing in tracing out the sequence of outbreaks of this fever." Dr. Wilson has also some suggestive observations on the application of by-laws in rural districts, and the present anomalous state of the law on the subject. A series of recommendations for securing the healthiness of houses, issued with the sanction of the Goole Rural Sanitary Authority, is stitched up with the reports.

Reigate (*Urban*).—Estimated population, 1880, 18,800; birth-rate 27·2 per 1000 inhabitants; death-rate 14·7. Mr. Jacob comments on the very low mortality of this urban district during 1880, a mortality which would have been designated as low even in a rural district. The district was, moreover, remarkably free from most of the dangerous zymotic diseases during the year. Not a single case of typhoid fever was reported at Redhill, showing how completely that portion of the district had shaken off all traces of the epidemic which accidentally visited it in the previous year.

Eccleshill (*Urban*), *Yorkshire.*—Estimated population, 1880, 7000; birth-rate 36·0 per 1000 inhabitants; death-rate 17·0. Mr. John Pitney Aston, in reporting upon the state of his district in 1880, by no means confines himself to the bare account of its health-condition, but endeavours to make his report interesting by giving to it, not unsuccessfully, certain literary graces. These, however, we must put aside, contenting ourselves with noting a progressive improvement in the mortality of the district during the past three years; the local peculiarity of three main sewers converging to *blind* terminations within fifty yards of the Mechanics' Institute, which we presume represents the intelligence of the town; and certain observations on privies. Mr. Aston is eloquent upon the ill-chosen position of these conveniences in many country houses and country places and the discomforts arising therefrom, and further, he says of their construction:—"Instead of being a bright, cheerful, little chamber, where you might pass five or ten minutes with a certain amount of comfort, and moralise on things in general, it is a cold, damp, repulsive room, which gives you the shivers to look at." This is in the right vein.

Epsom (*Urban*).—Estimated population, 1880, 7550; birth-rate 24·2 per 1000 inhabitants; death-rate 13·2. Mr. Jacob gives an interesting account in this report of a circumscribed outbreak of typhoid fever, probably caused by the entrance of sewage into the well of the town water-works through an overflow pipe which passed from the well into the town sewers. During a heavy downfall of rain the sewers are apt to become overcharged, and a fortnight or so before the fever appeared this had happened, and the water had risen in the manholes of the sewers to a height of seven feet above the level at which the overflow pipe from the well leaves it. It is tolerably certain that at this time there must have been a flow from this pipe of the contents of the sewer into the well, and Mr. Jacob shows that the circumstances of the fever, its mode of occurrence, and limitation of prevalence might very well be accounted for on the supposition that sewage had in this way become mingled temporarily with the well-water. The overflow pipe was at once closed and this source of danger removed.

Romford (*Rural*).—Mr. Alfred Wright reports for this district in 1880 a birth-rate of 34·9 per 1000 inhabitants, and a death-rate of 18·7. In considering the health-condition of the several parishes entering into the district he writes favourably of all except Barking and Ilford. Barking does not appear to exhibit many indications of sanitary improvement, and the newer and higher portion of the town is described as having no system of drainage, the sewage being discharged into private cesspools; and, as to Ilford, it is stated that although a system of drainage does exist, it is so imperfect "as really to be worse than none at all."

Whitechapel (*Metropolis*).—Mr. John Liddle reports that the death-rate of this district in 1880 was 24·3 per 1000 inhabitants, as compared with 26·0 in the preceding year. The tabular statements of sanitary work performed during the year show an astonishing amount of detailed supervision and inspection exercised by the officers of the sanitary authority. Mr. Liddle's annual report for 1880 appears as a part of his report for the last quarter of that year. In this last-named report he has some weighty observations on the want of more stringent regulations in the construction of houses.

TRICHINOSIS.

The Local Government Board for Ireland have recently issued a circular calling attention to the disease which has been attributed to the consumption by human beings of the imperfectly cooked flesh of pigs infested by trichinæ and similar parasites. It is upon the imported flesh of foreign pigs that special precautions should be taken, and the circular points out that the only means of avoiding disease in man from diseased pigs is by very thorough cooking. The Board also remind the sanitary authorities of the powers which they possess under sections 132-136 of the Public Health (Ireland) Act, 1878, in relation to the sale of unsound, diseased, or unwholesome meat, and suggest that they should enjoin their medical officer of health and sanitary sub-officers, to use special vigilance in carrying out the provisions of the above sections referred to.

On the 23rd ult., a meeting of representatives of the sanitary authorities of three counties was held in the County

Hall, Denbigh, to consider the action of Mr. Murray Browne (Local Government Board Inspector) and the Local Government Board in thrusting upon them a scheme for combination to appoint a single medical officer of health, against the wishes of the several authorities proposed to be united, and also against the opinion of the county (Denbighshire). Objection to the action of the Local Government Board seemed to be taken by the various speakers almost as much on account of the manner in which that Board had brought forward its proposal for combination as against the principle. It was determined to send a deputation to Mr. Dodson to make known to him the objections of the several authorities to the scheme, and, we may add, their determination to resist it.

Colonel Bolton, R.E., the water-examiner, reports that during the month of February the water in the Thames, at the intakes of the metropolitan companies taking supplies therefrom, was bad in quality from Feb. 1st to the 6th; from the latter date to the 23rd somewhat improved, but indifferent in condition; afterwards good to the end of the month. The water in the River Lea was generally good throughout the month. Most of the water, however, was delivered to the consumers clear and effectually filtered. Messrs. Crookes, Odling, and Tidy report that "the water supplied during the past month (February) was wholesome, of good quality, and well oxygenated."

A striking illustration is reported from Fulham of the danger of the spread of the disease arising from keeping small-pox cases in private houses. An instance is recorded of an unreported case there, from which contagion of the disease was conveyed to and infected twenty-seven other cases.

At a special meeting of the St. Pancras vestry on Monday, a motion affirming the expediency of providing a small-pox hospital for the parish was agreed to. The report of the Sanitary Committee recommended a site at Finchley; but it was decided that preference be given to a plot of ground adjoining the workhouse and the St. Pancras-gardens.

An outbreak of scarlet fever is reported to have broken out at the Fulham Small-pox Hospital. Eleven of the nurses have had to be removed to the Stockwell Fever Hospital.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

Mortality in the large English towns, although showing a slight further increase, continues considerably below the average for the season. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 5531 births and 3191 deaths were registered last week. The births exceeded by 345, while the deaths were 66 below, the average weekly numbers during 1880. The deaths, however, showed a further increase of 28 upon the low numbers returned in recent weeks. The annual rate of mortality, which had been equal to 20·6 and 21·7 in the two preceding weeks, further rose to 21·9 last week. The lowest rates in the twenty towns were 13·6 in Leicester, 17·2 in Sheffield, 17·5 in Norwich, 18·5 in Bradford, and 18·9 in Newcastle-upon-Tyne. The rates in the other towns ranged upwards to 25·6 in Hull, 26·2 in Bristol, 28·4 in Oldham, and 28·8 in Manchester. During the thirteen weeks ending on Saturday last the death-rate in the twenty towns averaged only 23·9 per 1000, against 25·7, the average rate in the corresponding periods of the five years 1876–80.

The deaths referred to the principal zymotic diseases in the twenty towns, which had been 287 and 321 in the two preceding weeks, were 315 last week; these included 66 from whooping-cough, 60 from scarlet fever, 55 from small-pox, 50 from measles, and only 28 from fever, principally enteric. The annual death-rate from these principal zymotic diseases averaged 2·2 per 1000 in the twenty towns, and ranged from 0·5 and 0·7 in Birmingham and Plymouth, to 2·8 and 5·4 in Liverpool and Wolverhampton. Whooping-cough showed the largest proportional fatality in Portsmouth and Liverpool; and scarlet fever in Wolverhampton and Sunderland. The 20 deaths from diphtheria in the twenty towns included 10 in London, 2 in Portsmouth, 2 in Birmingham, and 2 in Liverpool. The highest death-rate from fever (probably enteric) occurred in Wolverhampton. Small-pox caused 60 more deaths in London and its outer ring of suburban districts, one in Newcastle-upon-Tyne, and not one in any of the eighteen other large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 853 and 820 in the two preceding weeks, rose last week to 899, a higher number than has been under treatment in these hospitals since 1877. The number of new cases of small-pox admitted to these hospitals during last week was 256, against 265 and 147 in the two previous weeks. The Highgate Small-pox Hospital contained 87 patients on Saturday last, against 74 at the end of each of the two preceding weeks; 33 new cases were admitted during the week.

The deaths referred to diseases of the respiratory organs in London were 358 last week, against 345 and 348 in the two previous weeks; they were, however, no less than 131 below the corrected average number in the corresponding week of the last ten years, and included 221 which resulted from bronchitis and 88 from pneumonia. The annual death-rate from lung diseases, exclusive of phthisis, was equal to 5·0 per 1000 in London last week; while the rate from the same diseases was 7·0 in Liverpool.

The causes of 88, or 2·8 per cent., of the deaths in the twenty towns last week were not certified, either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths was equal to 2·1 per cent. in London, while it averaged 3·4 per cent. in the nineteen provincial towns. No uncertified causes of death were recorded last week in Portsmouth, Norwich, Leicester, or Nottingham; whereas the proportions of such deaths was largest in Hull, Leeds, Bradford, and Salford.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week declined to 20·7 per 1000, from 23·1 and 23·5 in the two preceding weeks; this rate was 0·2 below the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 16·9 and 17·0 in Paisley and Dundee, to 22·3 and 33·1 in Glasgow and Perth. The deaths referred to the principal zymotic diseases in the eight towns, which were 97 and 75 in the two preceding weeks, declined to 69 last week; they included 19 from diarrhœa, 16 from whooping-cough, 12 from diphtheria, 10 from measles, 7 from scarlet fever, 5 from "fever," and not one from small-pox. The annual death-rate from these zymotic diseases was equal to 2·7 per 1000 in the eight towns, which was 0·5 above the average rate from the same diseases in the twenty English towns. The zymotic death-rate in the eight Scotch towns ranged from 0·0 in Perth and 1·1 in Paisley, to 3·0 in Glasgow and Aberdeen and 3·6 in Edinburgh. The 19 deaths referred to diarrhœa showed an increase of 7 upon the number in the previous week, and considerably exceeded the average number in the corresponding week of recent years. The fatal cases of whooping-cough, which had been 31 and 27 in the two preceding weeks, further declined to 16 last week, of which 6 occurred in Glasgow, 5 in Dundee, and 3 in Edinburgh. The 12 deaths referred to diphtheria also showed a decline from recent weekly numbers, and included 9 in Glasgow and 2 in Edinburgh. The 10 deaths from measles, on the other hand, exceeded the numbers in recent weeks; 7 occurred in Glasgow and 3 in Aberdeen. The deaths from scarlet fever, however, further declined from 13 and 10 in the two previous weeks to 7, of which 6 occurred in Edinburgh and 1 in Leith. The 5 deaths referred to "fever" also showed a further decline, including 3 in Glasgow and 1 each in Edinburgh and Greenock; the death-rate from this cause in the eight towns was identical with that which prevailed in the twenty English towns during the week. The deaths referred to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy), which had steadily declined from 179 to 138 in the four preceding weeks, were 146 last week, and equal to an annual rate of 5·8 per 1000, against 4·1 from the same diseases in London.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, although again excessive, showed a decline last week. The annual death-rate, which had been equal to 30·4 and 34·9 in the two previous weeks, declined again to 30·8 last week. During the thirteen weeks ending on Saturday last the death-rate in the city, however, averaged 37·8 per 1000, against 23·4 in London and 22·3 in Edinburgh.

The 197 deaths in Dublin last week showed a decline of 26 from the number in the previous week, and included 15, or nearly 8 per cent., which were referred to the principal zymotic diseases, against 11 and 19 in the two previous weeks. These 15 deaths from zymotic diseases included 7 from fever (typhus, enteric or typhoid, and simple continued), 3 from scarlet fever, 2 from diarrhœa, 1 from small-pox, 1 from diphtheria, 1 from whooping-cough, and not one from measles. The annual death-rate from these zymotic diseases did not exceed 2·3 per 1000 in Dublin last week; it was 2·6 in London and 3·6 in Edinburgh. The deaths referred to fever in Dublin, which had been 4 and 12 in the two previous weeks, declined again to 7 last week; the annual death-rate from this cause was, however, nearly six times as high in Dublin as the average rate from fever in the twenty English towns. The fatal cases of scarlet fever were slightly more numerous than those in recent weeks; while those of other zymotic diseases show but slight variations. The deaths of infants were fewer than in any recent week; those of elderly persons, however, considerably exceeded the number returned in any of the four previous weeks.

THE HEALTH OF BERLIN IN 1880.

Berlin is the only European city that, besides London and Paris, can boast of a population exceeding a million. According to the Prussian census, the preliminary report of which has just been published, the population of this city, which was 969,050 on Dec. 1st, 1875, had increased to 1,122,385 at the recent census on 1st Dec. last. This is equal to an increase of not less than 15·8 per cent. in the five years, a rate of increase, however, which was considerably exceeded in several of the other large Prussian towns. The mean population of Berlin during 1880 is calculated at 1,107,100, and from a return recently issued from the City Statistical Bureau, it appears that the birth-rate during 1880 was equal to 39·8, and the death-rate to 29·7 per 1000 of this population. The birth-rate exceeded by 3·7, and the death-rate by so much as 7·5, the respective rates that prevailed during the year in London. This difference between the death-rates of London and Berlin signifies that in equal numbers living there were 134 deaths in Berlin last year to each 100 that occurred in London. Considerably more than 8000 persons died in Berlin during the year who would have survived if the death-rate had not exceeded that which prevailed in London. It is evident that a large proportion of this high rate of mortality is due to excessive infant mortality, which is of a remarkable character. According to the return before us more than 42 per cent. of the total deaths in the city last year were of infants under one year of age, while an additional 17 per cent. were of children aged between one and five years; thus, 59·5 per cent. of the total deaths were of children aged under five years. Berlin infant mortality, that is, the deaths of infants within one year of age, was equal to 314 per 1000 of the births registered. In London infant mortality last year, measured in this manner, did not exceed 158 per 1000. An infant born in Berlin, therefore, appears to have but half the chance of completing its first year of life as an infant born in London. The fatality of zymotic diseases was in the aggregate very large compared with that in London. Only 9 deaths were, however, referred to small-pox, and the fatality of measles and scarlet fever was not excessive. Fever fatality accounts for but a small proportion of the excess; no more than twenty-one deaths from typhus are reported, and the death-rate from enteric fever was scarcely more than twice as high as that which prevailed in London. Diphtheria is endemic in Berlin, as in so many other European and American cities, and caused no fewer than 1198 deaths last year, representing a mortality more than seven times as great as that in London, after due allowance for the difference of population. The main excess of zymotic fatality in Berlin was, however, due to diarrhœal diseases, which caused 5953 deaths in the city during the year, or more than 18 per cent. of the deaths from all causes; these were equal to a death rate of 5·4 per 1000 of the population, while the death-rate from the same causes in London last year did not exceed 1·1 per 1000, although diarrhœa fatality was exceptionally high in England in 1880. The excessive fatality from diarrhœal diseases in Berlin last year began in May and lasted till October. Further particulars of this remarkable diarrhœa fatality, especially the age distribution of the children who succumbed to the disease, would be full of interest in view of the Local Government Board investigation concerning infantile diarrhœa in England, which is now being conducted by Dr. Ballard.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

PORT INSPECTION IN BRITISH INDIA.

The Indian Merchant Shipping Bill, 1881, now under the consideration of the Government of India, provides for the appointment of port inspectors, and among other duties it prescribes that "the inspector may medically examine all or any of the persons on board" the vessels he inspects, and that "he may require and enforce the production of the log, and any other books or documents which he thinks necessary for the purpose of inquiring into the health and medical condition of the persons on board," &c. In the statement of "objects and reasons" attached to the Bill, it is observed of the port inspector that "this officer, in addition to performing the duties at present performed by the health officer (for the performance of which duties he is by the Bill invested with certain legal powers), is entrusted with the duty of inquiring into any legal complaints which may be made on the arrival of a ship in port by any of the crew against the master, or any others of the crew." The port inspector is to be required to perform important medical duties, but it does not appear that he must necessarily be a medical man.

THE PLAGUE.

The latest news of plague from the East announces the appearance of the disease in the city of Maragha, province of Azerbijan, Persia. It is reported that from the date (unstated) of the appearance of plague in Nedjef to 26th March, 1881, 49 cases and 24 deaths had occurred in that city, and 24 deaths from plague in Kufa.

Dr. Vacher has been lecturing at Birkenhead about "health and cleanliness," and he appears to have drawn some forcible lessons from the filthiness of habits of our ancestors in its bearing upon the great epidemics of plague and sweating sickness in the earlier periods of history of the kingdom, and the gaol fever and ship fever of more recent times. Judging from the abstract of the lecture given by the local press, it was too full of interest not to excite a hope that it will be given to the public in a complete form.

A systematic attempt is about to be made to improve the sanitary condition of the lodging houses of Oxford. The keepers of such houses have been informed that an engineer has been appointed to visit their establishments and make a thorough inspection of the premises at the cost of the University. Certificates will be furnished with respect to lodging houses whose sanitary arrangements satisfy the inspector.

THE SERVICES.

THE TRANSVAAL WAR.

Letters from the front have reached us, with some accounts of the medical arrangements of the field hospitals and plans for the relief of the wounded in the actions at Ingogo and Laing's Nek. At the Ingogo fight, which was quite unexpected, and for which therefore no field hospitals or dressing stations were ordered to accompany the column, the troops expecting merely to escort a provision convoy from Newcastle, Surgeon J. McGann, with five stretchers, twenty bearers, and some light equipment, was detailed for duty with the force. Surgeon-Major Babington, the senior medical officer with General Colley's army, immediately that heavy firing was heard in the Ingogo direction, despatched ambulances, ox waggons, a water cart, and stretchers, with a plentiful supply of medical comforts and surgical dressings, to the scene of action under the charge of Surgeons Ring and Landon. The party were, however, stopped by the Boers, who threatened to fire on them if they proceeded, and it was not till 4 o'clock next morning that they were able to reach the battle-field. Dr. McGann took on forty-two severely wounded men, with one officer, Lieutenant Parsons, R.A., to Newcastle, Surgeon Kirwan being despatched from that place with waggons to bring in the remainder. The wounded were treated in tents and empty buildings; hot soup, beef-tea, brandy, &c., being administered on arrival to all who required them; the wounds were dressed without delay, and several capital operations performed. The medical officers and men of the Army Hospital Corps worked indefatigably to ensure the comfort of the sufferers, many of whom having been exposed on the Ingogo plateau all night, with no shelter but a blanket from the cold wind and ceaseless rain, were in a very depressed and miserable condition. A convoy of wounded from Laing's Nek on February 8th was intercepted by the Boers on their way to Newcastle, the mules and oxen were seized and driven off, and the supplies of blankets and equipment looted. On receipt of this news at Newcastle, the senior medical officer, Dr. Stokes, promptly sent out medical comforts and necessaries by native runners, and at daybreak despatched four teams of mules to bring in the waggons; the party arrived safely in the afternoon of that day. At Newcastle the Base hospital, although filled with wounded from the recent actions, has met all requirements; but to make way for other possible casualties the Principal Medical Officer had ordered a convoy of men fit to travel to proceed to Pietermaritzburg, and so relieve pressure. The camp at Mount Prospect is kept in very good sanitary condition, the water supply is ample and good, procured from a mountain stream, great care being exercised to prevent its pollution by dead oxen or other animals being thrown into it. The camp refuse is burnt daily, the latrines are carefully attended to with dry or fresh earth, and the trenches and pits filled in as soon as they are within a couple of feet of the surface. Up to date of our correspondent's letters the rations had been very good, fresh meat issued daily, with preserved vegetables and lime juice. The rains had been very heavy, and of almost daily occurrence, but in spite of the discomforts of wet tents and clothing the general health of the troops was excellent. Surgeon W. E. Saunders has been appointed secretary to Deputy-Surgeon General Holloway, C.B., the Principal Medical Officer of the Transvaal field force.

GENERAL COLLEY'S DESPATCHES.

In a general order issued at Mount Prospect, Feb. 9th, the late General Colley refers to a medical officer as follows: "The Major-General feels sure the force engaged yesterday will join with him in specially recognising the distinguished conduct of Lieut. Parsons, R.A., and of Surgeon McGann, whose unremitting attention to the wounded under a heavy fire did honour to the branch of the profession to which he belonged."

The following officers of the Bombay Medical Service have been selected for promotion to the new rank of Brigade Surgeon:—Surgeon-Majors Bruce, Cook, Pinkerton, Joynt, Cruikshank, Colston, Carter, Langley, Blanc, and Dymock. The last officer will be supernumerary to the establishment for Bombay, which has been fixed at nine.

Surgeon-Major W. H. Bean, M.D., Madras Medical Service, has been promoted to the rank of Deputy Surgeon-General from the 28th March, vice Deputy Surgeon-General J. Wilson, retired.

Surgeon-Major Knaggs has been appointed to the medical charge of the Hill Station of Chaubutia, Bengal.

Surgeon-Major J. A. Anderson has embarked at Jamaica in medical charge of the 2nd West India Regiment, ordered to the Gold Coast for service in view of an Ashantee disturbance.

Admiralty.—Staff-Surgeon Charles John Fennell has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet, with seniority of March 31st, 1881.

University College Hospital.—The annual meeting of the friends of this hospital was held on the 2nd inst. under the presidency of the treasurer, Mr. Prevost. The total receipts for the past year had been £28,637, against £21,344 in 1879; the expenditure for 1880 was £28,024. The complete set of medicinal baths had been found of great use, not only to the patients of the hospital, but to those of private practitioners, for whom to a limited extent they were available on payment of fees. The dinner this year, it was announced, would be held at Willis's Rooms in May, and would be presided over by Prince Leopold.

THE INTERNATIONAL MEDICAL AND SANITARY EXHIBITION.

The applications for space already received leave no room to doubt that the forthcoming exhibition will be one of great importance, interest, and magnitude. Almost exactly a quarter of a mile of frontage has been applied for by some of the leading British and foreign instrument makers, pharmacists, opticians, and makers of sanitary apparatus. The committee have, nevertheless, deemed it advisable to extend the time for receiving applications from Great Britain and the Continent till the 16th of this month, the date which had been already named for the final reception of applications from America and the Colonies. Medical and sanitary literature will form an important feature in the show, and more than one of the leading medical publishers has applied for a considerable frontage. Diagrams and specimens of atlases will be hung upon the walls, and these, as well as the books, cannot but prove of interest to our foreign guests, many of whom are engaged in the business of imparting to students a systematic knowledge of their profession. Many applications have been received from individual members of the profession who wish to exhibit instruments, apparatus, statistical diagrams, &c. The fee for exhibiting a single article is almost nominal, and carries, we believe, with it a season ticket for the exhibition. These "single articles" will be an attractive feature, and we trust that members of the profession will make every use of this opportunity of imparting the results of their inventive faculties to their brethren. Another important element will be an attempt to represent visually the leading features of some of the health resorts of Great Britain and the Continent. Maps, plans, bird's-eye views, and tabulated statements of the leading features of health resorts (such as aspect, height above sea-level, nature of soil, population, means of sewerage and water-supply, special features, such as mineral springs or baths, arrangements for the accommodation and amusement of guests, &c.) will be displayed upon the walls, and we understand that one of our leading railway companies is taking steps to represent in this manner the health resorts to which it gives access. One of the difficulties which the committee foresaw in organising an exhibition like the present was the repression of the popular—not to say "quack"—element, and the mere advertiser. This difficulty has not yet arisen, for, with scarcely an exception, the applications for space have come from old established firms of acknowledged respectability, and the necessity for refusing space, on the grounds of the trivial or unsuitable nature of the proposed "exhibit," will probably be very small. The extension of time for making applications will certainly be appreciated. It will definitely come to an end, however, this day week (Saturday the 16th), so that those who have not yet secured their space must make application to the secretary, Parkes Museum, University College, without delay.

THE NAVAL MEDICAL SERVICE.

The *London Gazette* of Tuesday, April 5th, 1881, contains the following:—At the Court at Windsor, the 1st day of April, 1881. Present, the Queen's Most Excellent Majesty in Council.

Whereas there was this day read at the Board a Memorial from the Right Honourable the Lords Commissioners of the Admiralty, dated the 30th of March, 1881, in the words following, viz.:—

"Whereas we have had under our consideration the Regulations governing the position of Medical Officers of your Majesty's Navy, and whereas we are of opinion that it is desirable to effect certain modifications and improvements therein with a view of placing such officers in the position we consider it advisable should be granted to them, we would humbly submit for your Majesty's approval the following regulations for the remuneration, position, advancement, and retirement of the aforesaid officers, and we would submit that such regulations should take effect from 1st April, 1881, and be applicable only to officers on the Active List of the Royal Navy at that date, except that as regards surgeons entered since 1st January, 1881, we would submit such regulations be in force from the date of entry.

"*Numbers.*—1. The Active List of Medical Officers not to exceed—Inspectors and Deputy Inspectors-General of Hospitals and Fleets, 16 (of whom not more than four to be Inspectors-General). Fleet Surgeons, Staff Surgeons, and Surgeons, 400.

"*Promotion.*—2. An Inspector-General of Hospitals and Fleets to be selected from amongst deputy inspectors-general who have in that rank three years' foreign service; or four years' mixed service, of which not less than two to be abroad; or five years' home service in such appointments as preclude foreign service, and provided that they have not refused to go abroad if called upon.

"3. A Deputy Inspector-General of Hospitals and Fleets to be selected for ability and merit from amongst fleet surgeons.

"4. (*a*) The rank of Fleet Surgeon to be granted to Staff Surgeons on completion of twenty years' full-pay service, if recommended for advancement by the Medical Director-General, subject to our approval. (*b*) Power to be given to us to make, at our discretion, special promotions from the rank of Staff Surgeon to that of Fleet Surgeon in cases of distinguished service or conspicuous professional merit, such promotions to be exceptional, and not to exceed the rate of one in any two years. The total number at any one time of Fleet Surgeons holding that rank by such special promotions not to exceed six. (*c*) Officers who have been specially promoted to the rank of Staff Surgeon for distinguished service or conspicuous professional merit, to be eligible for promotion, if recommended by the Medical Director-General, to the rank of Fleet Surgeon after eight years' full-pay service as Staff Surgeon.

"5. (*a*) Rank as Staff Surgeon to be granted, subject to our approval, to surgeons at the expiration of twelve years from the date of entry, provided they are recommended by the Medical Director-General, and have passed such examination as may be required after completion of eight years from date of entry in the rank of Surgeon. (*b*) Power to be given to us to make, at our discretion, special promotions to the rank of Staff Surgeon, in cases of distinguished service, or conspicuous professional merit, such advancements to be exceptional, and not to exceed the rate of one a year. No officer to be so promoted unless he passes the examination prescribed for other Surgeons, but in such a case the requirement of eight years' service to be dispensed with. The total number at any one time of Staff Surgeons holding that rank by such special promotions not to exceed eight.

"*Relative Rank.*—6. Existing regulations to remain in force with the following exception—viz.: In all matters wherein the Army and Army Administration are concerned, Fleet Surgeons to rank with and as Brigade Surgeons.

"*Full Pay and Allowances.*—7. The undermentioned scale of full pay to be substituted for that now in force:—

Rank.	Daily.			Yearly.		
	£	s.	d.	£	s.	d.
Surgeon—						
On entry	0	11	6	209	17	6
After 4 years' full-pay service	0	13	6	246	7	6
„ 8 „ „	0	15	6	282	17	6
Staff Surgeon—						
On promotion	1	1	0	383	5	0
After 4 years' full-pay service in rank	1	4	0	438	0	0
Fleet Surgeon—						
On promotion	1	7	0	492	15	0
After 4 years' full-pay service in rank	1	10	0	547	10	0
„ 8 „ „	1	13	0	602	5	0

"8. The allowance of 5*s.* a day in addition to full-pay at present granted to the Fleet Surgeon of a flagship bearing the flag of a Commander-in-Chief on a foreign station to be given to the senior medical officer of such ship, whether a fleet or staff surgeon, and an allowance of 2*s.* 6*d.* a day to the senior medical officer (being a fleet or staff surgeon) of the ship of a commodore or of a senior officer commanding a foreign station. Allowances to be granted as follows to officers giving the course of instruction to surgeons on first appointment to the Naval Service:—To a medical officer of Haslar Hospital, conducting the course, £150 a year. To a junior medical officer of the same hospital, assisting him, £50 a year. No other alterations to be made in the allowances of medical officers.

"*Half-pay.*—9. The undermentioned scale of half-pay to be substituted for that now in force.

"*Retirement.*—10. Compulsory retirement to be as follows:—

Inspector and Deputy Inspector-General of Hospitals and Fleets	At the age of 60, or at any age if he has not served for 5 years	To be retired irrespective of age if found physically unfit for service.
Fleet Surgeon, Staff Surgeon, and Surgeon	At the age of 55, or at any age if he has not served for 5 years.	

"11. Voluntary retirement and withdrawal to be allowed as follows:—(*a*) Every officer to have the option, subject to our approval, of retiring after twenty years' full-pay service on the scale of retired pay, provided in paragraph 12, or on the scale of gratuities provided in that paragraph, if he is not eligible for retired pay. (*b*) At the expiration of eight, twelve, or sixteen years' full-pay service every officer to be permitted, subject to our approval, to withdraw from the Naval Service, receiving a gratuity on the scale laid down in paragraph 12. The name of an officer so withdrawing will be removed from the lists of the Navy, with which all connexion will then be severed. (*c*) Voluntary retirement and withdrawal to be allowed, as a rule, only when an officer is unemployed or serving at home.

"12. Gratuities and retired pay on the undermentioned scale to be granted on retirement and withdrawal:—

	Gratuities.			Daily.			Yearly.

Inspector-General				2	0	0	730	0	0

* To obtain this rate an officer must hold the Commission of Fleet Surgeon.

† Or on compulsory retirement at the age of fifty-five.

"13. An officer retired with less than twenty years' service, on account of disability contracted in, and attributable to the service, to receive the half-pay of his rank, or with our consent, a gratuity on the scales given in paragraphs 12 and 14 (*b*).

"14. An officer retired with less than twenty years' service, on account of disability contracted in, but not attributable to the service, to receive—(*a*) If he has over eight years' full-pay service, either a gratuity on the scale given in paragraph 12, or half-pay, according as we think fit. (*b*) If he has less than eight years' full-pay service, such gratuity as we may think fit, not to exceed the rate of £125 for each year of full-pay service.

"15. Under circumstances other than those specified in paragraphs 13 and 14, an officer retired with less than twenty years' service to receive a gratuity, on the scale laid down in paragraph 12, if he has eight years' full-pay service, and on that provided in paragraph 14 (*b*) should his full-pay service not amount to eight years. Half-pay or retired pay not to be allowed,—except that every officer on the Active List on 1st January, 1881, if compulsorily retired, shall be allowed, at his option, to receive half-pay, but subject to the provisions of Orders in Council for reduction of half-pay and retired pay.

"16. The power vested in us of granting reduced rates of half-pay and retired pay in cases of misconduct, to be extended to the award of gratuities on retirement, and the gratuity awarded in such case to be reduced to such amount as we think fit.

"17. An Officer retiring after 20 years' full-pay service to be eligible if recommended by the Medical Director-General for special reasons on account of distinguished or meritorious service, for a step of honorary rank, such step to be awarded at our discretion, and not to confer any claim to increase of retired pay or widow's pension.

"18. All retired Officers to be liable till the age of fifty-five, to be called upon to serve in time of declared national emergency in a rank not lower than that held on retirement. This liability not to exist in cases of withdrawal on the conditions specified in paragraph 11 (*b*).

"*Definition of Service.*—19. Service to reckon as follows:—(*a*) When borne on the books of any of your Majesty's ships or vessels, or when employed in Naval Hospitals or other Civil establishments at or under the Admiralty to be full-pay service for all purposes, but subject to the provisions in paragraph 2 as regards promotion. (*b*) Service under any other department which may be declared by us, with the consent of the Lords Commissioners of your Majesty's Treasury, to be for this purpose Naval Service, and Service on Commissions or Committees on Naval matters of importance to be full-pay service for such purposes, and to the extent to which it has hitherto reckoned as service under the provisions of Art. 216 of the Regulations of 1879, and those of Orders in Council of 22nd February, 1870, 18th May, 1870. (*c*) Time on half-pay to count as one-third service for increase of retired pay, but not for any other purpose.

"*Widows' Pensions.*—20. Where an officer retires or withdraws on a gratuity, his widow and children to have no claim to pension or compassionate allowance. 21. The undermentioned articles of the regulations and provisions of Orders in Council to be cancelled except as regards officers retired before 1st April, 1881. Queen's regulations and Admiralty instructions 1879. Articles 215 as regards medical officers; 219 the whole; 241 paragraphs *a* to *d* inclusive. 265, the whole. Appendices XX. and XXIII., as far as relates to full-pay and half-pay of medical officers. Order in Council 22nd February, 1870. Section V. the whole. Section VIII. the whole as far as relates to medical officers. Section IX. the whole as far as relates to medical officers. Section X. the scale of retired pay, and paragraphs 2 and 3, as far as medical officers are concerned. Section XII. as regards medical officers. Order in Council 4th February, 1875, the whole. We would represent to your Majesty that the Lords Commissioners of your Majesty's Treasury have assented to the above proposals."

Her Majesty having taken the said Memorial into consideration, was pleased, by and with the advice of Her Privy Council, to approve of what is therein proposed. And the Right Honourable the Lords Commissioners of the Admiralty are to give the necessary directions herein accordingly. C. L. Peel.

NOTIFICATION OF INFECTIOUS DISEASES BILL (IRELAND).

To the Honourable the Knights, Burgesses, and Commons in Parliament assembled.

The petition of the President and Council of the Irish Medical Association humbly sheweth:

That your petitioners are the executive of an association devoted to representing the opinions and interests of the medical profession in Ireland, and includes amongst its members a large proportion of the legally qualified medical men in practice in Ireland. That your petitioners have fully considered the notification of Infectious Diseases (Ireland) Bill now standing for a second reading in your honourable House, and have obtained the opinion of a large majority of the medical practitioners of the City of Dublin upon the chief proposals contained in said Bill, which opinion has been expressed by a majority of nearly two to one against any proposal which would require the medical attendant to notify in writing the occurrence of infective disease either to the sanitary authority or to the house occupier.

Your petitioners confirm the opinion thus expressed, and consider that the provisions of said Bill are not calculated to effect with certainty the discovery of infective disease in those instances in which concealment is most probable, while they will, if passed into law, impose upon the medical profession new functions inconsistent with the efficient performance of their duties towards their patients, and seriously prejudicial to their interests as practitioners.

That your petitioners apprehend that if, as would occur under the operation of said Bill, the visit of the physician be followed by the immediate enforcement of sanitary precautions, a great inducement will be created, in all instances in which it is desired by the house occupier to avoid the application of the sanitary law, to omit sending for a medical attendant, or to defer doing so until the disease had reached a stage in which its treatment would be difficult and ineffective. Your petitioners, therefore, anticipate that the number of undetected cases of infective disease might rather increase than diminish under the operation of the proposed law, while in many instances the chances of restoration of the patient to health would be greatly prejudiced.

Your petitioners humbly submit that the professional and monetary relations existing in Ireland between the physician and his patient are altogether different from those which exist in other divisions of the kingdom, and furthermore, that the methods of application of sanitary law in Ireland are not fairly comparable with those which exist elsewhere; and your petitioners therefore submit that a system of notification of infective disease applicable to England and Scotland may prove altogether unsuitable to Ireland, and they are of opinion that any enactment which requires the medical attendant in Ireland to give a written certificate of the disease from which his patient is suffering will be inoperative in many instances, and will tend to increase the evil which it purports to remedy.

Your petitioners are furthermore strongly of opinion that in respect of the fee proposed to be paid for such notification, the penalty imposed for omission to notify, and in other details, the said Bill is altogether objectionable.

Your petitioners, therefore, humbly pray that your honourable House will not pass said Bill.

(Signed) J. Chapman, President.
R. Browne, Hon. Sec. of Council.

ABERDEEN UNIVERSITY.

The winter session at Aberdeen concluded on Friday last, when Lord Rosebery, Rector of the University, attended and presided at the ceremony of graduation in Arts, and addressed the graduates in felicitous terms. His Lordship on this occasion was accompanied by the Countess, and there was a large attendance of the general public and much enthusiasm displayed by the undergraduates. In concluding the winter session in the medical school Professor Struthers referred to the change in the order of the examinations just effected by an order of the Queen in Council, approving of certain alterations on the Ordinance of the Scottish Universities Commissioners regulating graduation in Medicine in the University. The examinations in Botany and Natural History would now take place at the end of the summer session preceding the second winter session, instead of at the more advanced period of the curriculum, which had been found to interfere with the more strictly professional work. The examination in Materia Medica would now take place at the end of the third, instead of prematurely at the end of the second year, when the student could hardly be expected to understand therapeutics.

Dr. Struthers warmly congratulated the students on the better direction which these changes would give to their medical studies. A change is also made on the relation of the examinations in Anatomy. Instead of the examination in Elementary Anatomy at the end of the second year, and in Advanced Anatomy at the end of the third year, the terms to be used in future would be Anatomy, and Regional Anatomy, which would give a better direction to both the earlier and later parts of anatomical study.

Dr. Struthers referred also to the propriety of obtaining a larger number of bursaries and scholarships for the medical side of the University, which is but scantily provided with these rewards, while in the Faculty of Arts there are 240 bursaries and various well endowed scholarships. The students of medicine in Aberdeen had now grown to be a large body, no less industrious and no less deserving than the students in the sister Faculty, and he saw no reason why scholarships and large rewards should be attached to the study of Latin and Greek and not to such studies as Chemistry, Anatomy, or Physiology. He trusted that intending benefactors of the University would keep in mind where there is plenty and where there is need.

MEDICAL NOTES IN PARLIAMENT.

Means of Exit from Theatres.

IN the House of Lords on Tuesday, Lord Kenmare, replying to an inquiry by the Duke of St. Albans, said that the theatres had better means of exit than any other public buildings in the metropolis. In that respect they had been improving, and the improvements were being continued. He would lay on the table a return relating to this subject.

In the House of Commons on Thursday, 31st ult., a petition was presented from Charles Colsten for inquiry into the East India Army Medical Department. The Alkali Works Bill was read a second time. Mr. Warton gave notice that on Friday, April 8th, on going into Supply, he would move a resolution in favour of suppressing trade combinations, which had for their object the undue increase of the price of food. Mr. Errington and Mr. Dillwyn put down amendments for committee on the Alkali Bill.

On Friday, Sir Herbert Maxwell brought forward his resolution against the importation of spurious butter, which was opposed by the Government on the ground that the compounds imported under the name of butter were not hurtful. The chief feature of the debate was a remarkable speech by Dr. Lyon Playfair in support of the position taken by the Board of Trade. The resolution was rejected by the narrow majority of 14—75 to 59. Sir J. M'Garel Hogg, Chairman of the Metropolitan Board of Works, gave notice that in Committee on the Alkali Bill he would move a clause to exclude any works within the metropolis from the operation of the Bill. Mr. Cochrane Patrick gave notice that in Committee of Supply he will move to reduce the English medical relief grant by £20,000, doubtless with the object of renewing the Scotch demand for an increased medical grant in that country.

On Monday, a petition was presented from Fife and Clackmannan for extension to Scotland of the system of coroners' inquests.

On Tuesday, a return was presented of the number of examinations held in London for appointments to the Army Medical Service. Mr. Chamberlain, in reply to a question by Mr. Dixon Hartland, as to a recent seizure of 200 putrid American hams in the Central Meat Market, said he believed the ordinary law was sufficient to meet such cases. He saw no necessity for asking the American authorities to prohibit similar exportations, believing that the influence of the consignee upon the consigner would be more efficacious.

On Wednesday, Mr. Litton's Lunacy Law Assimilation (Ireland) Bill was read a second time, and committed for Wednesday, 1st June. Sir Hervey Bruce will move that the Bill be referred to a Select Committee; and Mr. Warton has put down a notice that he will move the rejection of the Bill. Mr. Dillwyn gave notice that in Supply he will move to reduce the vote for Broadmoor by £500.

Small-pox.

On Thursday, Mr. Dodson, in reply to Sir S. Waterlow, said his attention had been for some time anxiously directed to the prevalence of small-pox within the metropolis. The Government had no power to make special arrangements for the care of patients suffering from that disease; but the Local Government Board had not refrained from impressing upon the several authorities who were liable to provide accommodation for small-pox patients, whether they belonged to the pauper or non-pauper class, the necessity of making every arrangement in their power; and he was glad to say that arrangements were being made to supplement the hospital accommodation.

Glanders.

Mr. Mundella, in reply to Lord C. Hamilton, said there had no doubt been an increase in the number of cases reported of horses with glanders in 1880 as compared with the number in 1879, but it was believed that that was due to the more rigid enforcement in the latter year of the Act of 1878, and not to the greater prevalence of the infection. It was a fact that drinking troughs were one source of spreading the infection; and it was also true that horses infected were for the most part worked during the night hours, probably on account of the facility the darkness afforded of avoiding detection, but it must be remembered that when they were detected the penalties were more severe.

THE CHLOROTIC MURMUR.

To the Editor of THE LANCET.

SIR,—I have no fault to find with Dr. Bramwell's quotation; it is quite correct, but by no means warrants his conclusion. I still maintain that "the so-called basic murmur of chlorosis is never arterial." That, however, is not quite the same as "*denying* that the inorganic murmurs of chlorosis are *ever* arterial." In my sixth chapter, first edition, I am occupied solely in discussing the *primary* murmur of chlorosis, and having given it as my belief that *this primary* murmur is "*never arterial*," but always strictly cardiac in character, being produced by regurgitation through the mitral valve, due to dilatation of the heart, I hold that, both logically and pathologically, I left it to be inferred that the *ultimate result* must be a systolic arterial murmur. When Dr. Bramwell, therefore, states that I deny that such a murmur can ever occur, this only shows that he has completely misunderstood me. In a subject of so much importance I think he was bound to use the utmost care not to misinterpret my views, if they were worth quoting at all; and I also think that I do not ask too much of a *teacher* of medicine, that besides the usual text-books he should also be acquainted with at least so much of the literature of the subject he is writing about as is to be found during the last five years in the pages of the journal he writes in.

Hayden and Fothergill are anew imported into the controversy, but as the opinions they have expressed are quite beside the mark, I do not require to enter the lists against them. I have said that the separation between the systolic and the diastolic closure of the segments of the pulmonary valve, caused by the increase of the arterial blood-pressure within the pulmonary circuit, supplies what seems to me to be the only rational explanation of a reduplicated second, having due regard to all the facts of the case. Dr. Bramwell asserts that this explanation cannot be accepted because some professor of physiology, whose name he does not give, Dr. Fothergill, and he himself, regard this systolic closure as soundless. Ceradini has, however, stated it as a matter of fact, that the systolic closure of the arterial valves is attended by an audible snap; it is with him, therefore, and not with me, that this part of the controversy must be settled. I am, Sir, yours obediently,

Edinburgh, March 28th, 1881. GEORGE W. BALFOUR.

REMARKABLE CASE OF EARLY MATERNITY.

To the Editor of THE LANCET.

SIR,—On August 8th, 1871, I attended Mrs. F. M——, a joiner's wife, during confinement, and delivered her of a female child. There was nothing remarkable about the infant until it was twelve months old, when it commenced to menstruate, not very regularly at first, varying from one month to six weeks between the periods; the last two years the catamenia have been very regular indeed, never more than three weeks elapsing between the periods. They ceased on June 22nd, 1880 (her mother's statement), when she became pregnant. There is nothing very remarkable in appearance about the child. The hirsute growth over the pubes and in the axilla is profuse, the breasts are large, and at present gorged with milk. She is a very active, hard-working girl, and has for the last year done all her mother's washing; in fact, the night before she was confined I saw her myself hanging the day's washing on the clothes-line in her father's garden. Her labour pains did not continue over six hours from first to last. I administered chloroform, and kept the body well supported with bandages during labour.

The child was a large one, and weighed 7 lb. It has since died in convulsions; its left foot had only three toes on it. This young mother is now nine years and eight months old, and must have been pregnant two months before she reached the age of nine. Yours obediently,

Henry Dodd, M.R.C.S., &c.

Rillington, York, March 24th, 1881.

GLASGOW.

(*From our own Correspondent.*)

The Faculty of Physicians and Surgeons of Glasgow has had under consideration a proposal to institute an examination for the higher of the two qualifications, both registrable, which it grants. This proposal was rejected at a recent meeting, mainly by the vote of the older and more conservative Fellows. The grounds on which the suggested change was advocated were that at present there is no high qualification in surgery obtainable in Scotland, that it is illogical that the Faculty should demand an examination for its lowest diploma, and yet grant its higher one by ballot and purchase, and that it would be better to retire gracefully from its present position now than to be forced from it a short time hence under pressure from without. The principal argument urged in favour of the existing arrangement was the statement that candidates for the Fellowship must not only pay £50 and risk a ballot, but must also already be in possession of a registrable qualification, examination being thus rendered unnecessary. This question, it is believed by those who profess to be able to discern the signs of the times, is one which will again force itself on the attention at no very distant date.

The following appointments have been made by the Glasgow University Court:—Dr. H. C. Cameron of Glasgow to be examiner for the next four years in Surgery and Clinical Surgery; Dr. D. Fraser of Paisley, to be examiner for the same period in Medicine and Clinical Medicine; Dr. A. Macalister, of Trinity College, Dublin, to be examiner for the same period in Physiology and Pathology.

Dr. A. Wallace has been appointed to the chair of Midwifery in Anderson's College, rendered vacant by the death of Dr. J. G. Wilson. Dr. S. Sloan stood second in the estimation of the Trustees, Dr. W. L. Reid third.

At the meeting which closed the winter medical session at Anderson's College, a few days ago, the Chairman referred to the wonderful prosperity of the College during the past few years, and read some statistics which, as they are the only trustworthy evidence on this point which has hitherto been obtainable, are worth quoting. The number of students attending the medical classes of the college in the session 1877–78 was 70; in 1878–79, 86; in 1879–80, 91; in 1880–81, 110. These are large numbers for an extra-mural school, and they indicate a high and well-deserved degree of prosperity. All that is now wanting to complete information is that the other extra-mural schools should publish similar statistics.

PARIS.

(*From our own Correspondent.*)

The report of the Commission appointed by the Academy of Medicine to study the question of compulsory vaccination was read by M. Blot, in the name of his colleagues, on the 29th of March. M. Blot began by stating that it is unnecessary to bring forward any further proof of the value of vaccination—the events of 1870–71 have amply demonstrated this point. The only objection to the practice of any importance is the danger of inoculating syphilis with vaccinia; but even this eventuality, which science has reduced to a minimum, is rendered impossible by the use of animal vaccine. It has been said that compulsory vaccination is an infringement of the liberty of the subject; but M. Blot considered that this liberty ends where common interests begin. The privilege of disseminating disease is certainly contrary to the public welfare, and inasmuch as all other hygienic measures—such as isolation, disinfection, &c.—have proved insufficient to prevent the spread of small-pox the Government is justified in imposing such prophylactic means as have remedied the evil in other countries. The conclusions of the report, which have been adopted by eleven out of the twelve members forming the Commission, are as follows:—

"Considering that vaccination is, with rare exceptions, an inoffensive operation, when performed with care upon healthy subjects; and that, without vaccine, other hygienic measures, such as isolation and disinfection, are in themselves insufficient to prevent small-pox; that the belief in the danger of vaccination and revaccination during epidemics is unfounded; and that, lastly, revaccination, the necessary complement of vaccination, should be practised at least within ten years after a successful vaccination, and repeated as often as possible, when not followed by characteristic cicatrices—on these grounds the Academy is of opinion that there is urgent need in the public interest of a law rendering vaccination compulsory. As regards revaccination, it should be encouraged in every way, and required by public services (*règlements d'administration*) as far as it is within their power."

The twelfth member of the Commission, M. Depaul, states that he is perfectly agreed with his colleagues on all the questions which are dealt with in the report, and that he is prepared to vote for all the ideas there expressed, except the conclusion rendering vaccination compulsory. According to him the rights of a father of a family are paramount over those of the State, and the father, or mother, or the natural guardian of a child should be free to vaccinate it or not, as he may have confidence or not in the utility of the practice. Not only, says M. Depaul, is compulsory vaccination vexatious, it is also inapplicable. Those who have taken the trouble to inquire into the matter know that in England and Germany the law on the subject remains a dead letter. It exists, but it is not enforced. Everything should be done to encourage vaccination and revaccination, but there should be no obligation. What is required is money. Hitherto the Government has done almost nothing, the sum expended on vaccination in the whole of France only amounting to 240,000 francs (less than £10,000), which represents five francs per thousand of the population, and from three to four centimes (one-third of a penny) for each vaccination. With a proper expenditure an efficient service might be organised, a number of vaccinating centres created, and human lymph supplemented by an animal supply. Lastly, it would be as well to pay an adequate fee for the operation, to those who perform it, instead of, as is now the fashion, praising the zeal and devotion of the country practitioner, but leaving his labour unrewarded. The adjourned discussion, which took place yesterday afternoon, brought forward MM. Fauvel and Jules Guérin, the former in favour of the views of the Commission, and the latter naturally against them. Not that M. Guérin is an opponent of vaccination; on the contrary, he declares it excellent, and uses all his endeavours to promote it. But the practice being looked upon as dangerous by some, he considers that a compulsory law would weigh on their consciences in obliging them to further an operation of which they disapprove. Under these circumstances the Academy cannot refuse to take such objections into account, and must not, he thinks, risk its scientific prestige by pronouncing in favour of compulsion.

Paris, April 5th, 1881.

The Levee. — The following members of the medical profession were presented at the Levée held on Tuesday at St. James's Palace by the Prince of Wales:—Surgeon-General A. Shatton; Surgeon-Majors Allen, J. Candy, M.D., and H. F. L. Melladew; Surgeons C. J. Addison, W. J. Baker, W. G. A. Bedford, H. J. Barnes, A. P. Hart, F. A. Harris, C. B. Lewis, E. L. Maunsell, J. H. Nicholas, H. S. Parker, R. Porter, D. L. Porter, T. H. Parke, W. W. Pope, W. F. Spencer, M.D., W. C. Wise, M.D., and C. L. Young; Dr. Halford, of Melbourne; and Fleet Surgeon C. Strickland.

Royal College of Surgeons in Ireland.—The prizes at the termination of the winter session in the Medical School have been awarded to the following:—First year: first prize, gold medal and £10, Michael T. Yarr; second prize, £10, W. D. Waterhouse. Second year: first prize, £12, Austin M. Cowper; second prize, £8, Myer M. Dutch. Third year: first prize, £10, Whitby B. Stokes; second prize, £5, Langford Simms; third prize, £2, G. W. Elsner.

Medical News.

Royal College of Surgeons of England. —The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners on Monday, Tuesday, and Wednesday last:—

J. N. Kaye, Edgar Beaumont, and Herbert Child, Leeds School of Medicine; Rudolph J. Maas, McGill College, Canada; John Kæser, Basle, Switzerland; Bryce Gordon, Medical College, Bombay; Henry G. Beyer, New York and Leipzig; James Limont, Edinburgh; David C. M. Lunt, Frederick W. Bennett, Lewis Brown, Gilbert L. Barrett, William A. Evans, Robert Jennings, John H. Jones, Harry F. Wylde, Ernest S. Reynolds, John Stevenson, and William E. Wilson, Owens College, Manchester; John H. Potter, Sheffield; Robert S. Coulthard; Edgar H. Hughes, Harold Simmons, and William C. Lysaght, Bristol; Arthur Overton, William O. Travis, and Arthur W. Davison, Liverpool; Isaac Hartley and Arthur Hepworth, Newcastle-on-Tyne; Charles J. Evers, Birmingham; Leonard H. Armstrong, Cambridge; Robert H. Peck and Robert H. Martin, University College; Frederick W. Hatchett and Ambrose E. L. Charpentier, St. Thomas's Hospital; Percy H. Mander and Charles B. Waller, Westminster Hospital; George Thomas and William J. Black, Owens College, Manchester; James T. Lilburne, Cambridge; Joseph A. Hutchinson, Newcastle-on-Tyne; Herbert J. Robson, Leeds; Haward A. Bredin, Liverpool; Hugh C. Thurston, Bristol; John W. Bentley, Owens College, Manchester; Francis J. C. Mason, St. Bartholomew's Hospital; George W. Hill, St. Mary's Hospital; William C. Parsons, London Hospital; Thomas Greaves, New York and King's College, London; Arthur W. Ogle, Middlesex Hospital; Walter B. Platt, Berlin and Vienna.

Apothecaries' Hall. —The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on March 31st:—

Locke, George, Aylesbury.
Morris, Gerald de Courcy, M.D. New York, Albany-street.

The following gentlemen also on the same day passed the Primary Professional Examination:—

William Edward Dawson, London Hospital; Arthur Lumley Tireman, Guy's Hospital.

Mr. William Soper has resigned his post as member of the Stockwell Hospital Committee.

Dr. A. B. Garrod, F.R.S., and Dr. J. L. Sullivan have been elected Members of the Royal Institution.

The Governors of the Royal Berkshire Hospital have decided to expend £16,000 in altering and enlarging the building.

Mr. George P. Dale, F.R.C.S. Eng., of Falconer House, Scarborough, has been placed on the Commission of the Peace for the North Riding of Yorkshire.

Mr. Albert Napper, late of Cranleigh, so well known in connexion with the establishment of cottage hospitals, has received, on the occasion of his leaving the town, a gratifying proof, in the shape of a purse of £242, of the esteem in which he is held by his friends and neighbours.

A sum of £120,000 is to be raised on mortgage of the county rates for the purpose of erecting additional buildings, capable of containing 1000 patients, at the Rainhill Lunatic Asylum, Lancashire.

Mr. Charles Brook, Surgeon to the Lincoln County Hospital, has made a donation of £50 to its funds, "in token of his appreciation of the great excellence of the nursing in that institution at the present time."

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the lates*

Atkinson, F. H., L.F.P.S.G., has been reappointed Medical Officer for the Bennington and New Leake Districts of the Boston Union.

Barry, E. F. S., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Visiting Physician to Kanturk Union Workhouse, vice O'Shaughnessy.

Bathe, A. J., M.R.C.S.E., L.R.C.P.L., L.S.A.L., has been appointed Assistant Medical Officer to the Greenwich Union Infirmary, vice C. H. Hartt, resigned.

Cheshire, H. F., F.C.S., has been appointed Public Analyst for the Borough of Hastings, vice Ashenden, resigned.

Coombs, S. W., F.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer of Health to the Claines Local Board, Worcester.

Critchett, G. Anderson, M.A., M.R.C.S.E., has been appointed Ophthalmic Surgeon to St. Mary's Hospital, vice Wharton Jones, resigned.

Dinwoodie, W., M.D., M.Ch., has been appointed Medical Officer for the Elsdon District of the Rothbury Union.

Fenn, E. L., M.D., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer for In-patients of the Richmond Hospital, vice Dunn, resigned.

Fox, T. C., M.B., M.R.C.S.E., has been appointed Physician to the Skin Department of the North-West London Free Dispensary for Sick Children, Edgware-road.

Gibbes, H., M.B., L.R.C.P.L., has been appointed Curator to the Anatomical Museum, King's College.

Greasley, C., L.F.G.S., has been appointed Medical Officer for the Yoxall District of the Lichfield Union.

Hartt, C. H., L.R.C.S.I., L.K.Q.C.P.I., & L.M., late Assistant Medical Officer to the Greenwich Union Infirmary, has been appointed Medical Officer to the Central District of Greenwich.

Hawkins, H., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Fourth District of the Ware Union.

Hepburn, A., M.R.C.S.E., M.S.A.L., L.S.A.L., has been appointed House-Surgeon and Secretary to the Chelsea, Brompton, and Belgrave Dispensary, vice A. Buchanan, M.D., resigned.

Kirby, T. C., L.K.Q.C.P.I. &c., has been appointed Consulting Physician to the North-West London Free Dispensary for Sick Children, Edgware-road.

Mall, H. C., M.B., C.M., has been appointed Assistant House-Surgeon to Leith Hospital.

Maturin, L., L.K.Q.C.P.I., has been appointed Temporary Superintendent of the Kilmainham Fever Hospital, Dublin.

Shaw, C. K., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer of Health for the Hastings Urban Sanitary District, vice Ashenden, resigned.

Stuart, S., M.D., L.R.C.S.Ed., has been appointed Assistant Medical Officer at the Liverpool Workhouse.

Wadd, F. J., M.B., C.M., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for Out-patients of the Richmond Hospital, vice Fenn, appointed to the care of In-patients.

Whitham, A., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer of Health for the Adlington Local Board District; also Medical Officer for the Rivington District of the Chorley Union.

Wood, W. J. H., L.R.C.P.Ed., L.R.C.S.Ed., M.R.C.S.E., has been reappointed Medical Officer for the Skirbeck District of the Boston Union.

Births, Marriages, and Deaths.

BIRTHS.

Biggs.—On the 28th ult., at 93, Northcote-road, S.W., the wife of M. G. Biggs, M.R.C.S.E., of a son.

Buck.—On the 3rd inst., at Camden-road, the wife of Alfred H. Buck, M.R.C.S.E., L.R.C.P., of a daughter.

Deane-Butcher.—On the 30th ult., at Friar-street, Reading, the wife of W. Deane-Butcher, M.R.C.S.E., of a son.

Eager.—On the 3rd inst., at The Limes, Woking, the wife of T. Cawley Eager, M.D., of a son.

English.—On the 5th inst., at Fulham-road, S.W., the wife of T. Johnston English, M.D., of a daughter.

Gibson.—On the 4th inst., at Stanley House, Blackstock-road, Finsbury-park, the wife of J. C. Gibson, M.R.C.P., L.R.C.S., & L.M. Ed., of a daughter.

Hyatt.—On the 31st ult., the wife of Brownlow North Hyatt, M.R.C.S.E., of Shepton Mallet, of a son.

Jordison.—On the 5th inst., at Malpas, Cheshire, the wife of Christopher Jordison, of a son.

Kay.—On the 26th ult., at Bentley Cottage, Bentley, Hants, the wife of William Kay, M.R.C.S.E. (prematurely), of a son.

MARRIAGES.

Gray—Mountford.—On the 31st ult., at St. Luke's, West Holloway, Wellington Gray, Surgeon-Major H.M.'s Bombay Army, to Jane, only daughter of William Mountford, Esq., of Shipston-on-Stour.

Jones—Hicks.—On the 2nd inst., at St. John's, Notting-hill, William Jones, L.R.C.P., L.R.C.S., L.S.A.L., of Edmonton, to Emily Elizabeth, eldest daughter of George Hicks, Esq., of Royston Villa, Bayswater.

Pye—Kidston.—On the 1st inst., at 27, Blythswood-square, Glasgow, by the Rev. James Black, D.D., Walter Pye, F.R.C.S., of London, to Anna, daughter of J. B. Kidston.

Wherry—Cust.—On the 2nd inst., at St. Botolph's Church, Cambridge, by the Rev. W. M. Campion, D.D., Rector, Hon. Canon of Ely and Rural Dean, George Edward Wherry, M.C. Cantab., F.R.C.S., to Albinia Lucy, eldest daughter of Robert Needham Cust, Esq.

DEATHS.

Dove.—On the 31st ult., at St. Stephen's-square, Bayswater, William Watson Dove, L.R.C.P.Ed., late of Alexandria, eldest surviving son of the late Charles Kemp Dove, Postmaster-General of Bengal, aged 33.

Gamble.—On the 21st February, on board H.M.S. *Trojan*, lat. 6.57, long. 14.3 west, Ernest Langwith Gamble, M.R.C.S.E., L.R.C.P., L.S.A.L., second son of the late Richard Gamble, of Grantham, aged 25.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, April 11.

Royal London Ophthalmic Hospital, Moorfields. — Operations, 10½ A.M. each day, and at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1½ P.M. each day, and at the same hour.

Metropolitan Free Hospital.—Operations, 2 P.M.

Royal Orthopædic Hospital.—Operations, 2 P.M.

St. Mark's Hospital.—Operations, 2 P.M. ; on Tuesday, 9 A.M.

Medical Society of London.—8.30 P.M. Mr. George Lawson will read a short paper showing the evil results which follow Partial Operations in cases of Cancer of the Breast.—Mr. Reginald Harrison (of Liverpool), "On Acute Prostatitis."

Tuesday, April 12.

Guy's Hospital.—Operations, 1½ P.M., and on Friday at the same hour

Westminster Hospital.—Operations, 2 P.M.

West London Hospital.—Operations, 3 P.M.

Royal Medical and Chirurgical Society.—8.30 P.M. Mr. C. Higgens, "On a Case of Vascular Protrusion of the Eyeball."—Mr. Arthur E. Barker, "On Nephrectomy by Lumbar Section."

Wednesday, April 13.

National Orthopædic Hospital.—Operations, 10 A.M.

Middlesex Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital. — Operations, 1½ P.M., and on Saturday at the same hour.

St. Thomas's Hospital. — Operations, 1½ P.M., and on Saturday at the same hour.

St. Mary's Hospital.—Operations, 1½ P.M.

King's College Hospital. — Operations, 2 P.M., and on Saturday at 1 P.M.

London Hospital.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

Great Northern Hospital.—Operations, 2 P.M.

University College Hospital. — Operations, 2 P.M., and on Saturday at the same hour.

Samaritan Free Hospital for Women and Children. — Operations, 2½ P.M.

Royal Microscopical Society. — 8 P.M. Messrs. W. H. Shrubsole and F. Kitton, "On the Diatoms of the London Clay."

Thursday, April 14.

St. George's Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital.—1½ P.M. Surgical Consultations.

Charing-cross Hospital.—Operations, 2 P.M.

Central London Ophthalmic Hospital. — Operations, 2 P.M., and on Friday at the same hour.

Hospital for Women, Soho-square.—Operations, 2 P.M.

North-West London Hospital.—Operations, 2½ P.M.

Friday, April 15.

St. George's Hospital.—Ophthalmic Operations, 1½ P.M.

St. Thomas's Hospital.—Ophthalmic Operations, 2 P.M.

Royal South London Ophthalmic Hospital.—Operations, 2 P.M.

Saturday, April 16.

Royal Free Hospital.—Operations, 2 P.M.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of The Lancet *to be addressed "To the Publisher."*

Medical Education in the United States.

The result of an experiment with the object of improving medical education in the United States may not be without interest for medical teachers in this country. It appears that the faculty of the Bellevue Hospital Medical College introduced, for the session 1880-81, important changes in the curriculum of instruction and in the requirements for graduation. The preliminary term was abolished, and the regular winter session was extended to six months. Attendance upon three winter sessions was made obligatory. Students were required during the first two years to attend all the lectures, didactic and clinical, and at the end of the first and second years to pass examinations in chemistry, anatomy, physiology, materia medica, and therapeutics. An examination in these branches having been passed, the third year was to be devoted to the practical departments of medicine, surgery, and obstetrics. The experience of the session of 1880-81, however, has led the Faculty reluctantly to the conclusion that to persist in the requirement of attendance during three courses would be to run a risk which they do not feel justified in incurring, and they accordingly announce that after the present session attendance during a third course will be optional. The non-success of the change is attributed by the college authorities, rather inconsequently, we think, to the apathy of the profession. The *Boston Medical and Surgical Journal* has some remarks of wholesome criticism on the want of courage on the part of the Bellevue Faculty and their readiness to take alarm at the prospect of failure before the experiment has been fairly tried.

Mr. G. S. Wilkins.—"Fomites" is the plural of "fomes" (fuel, anything that retains heat).

L. F. P. S.—The appointment is strictly in the hands of the guardians.

A CASE OF SUCCESSFUL REVACCINATION AFTER NATURAL COW-POX.

To the Editor of The Lancet.

Sir,—On March 22nd I revaccinated M. H——, a servant in the neighbourhood, who had been successfully vaccinated when a child, one mark remaining, and afterwards when in Ireland she caught cow-pox while milking a cow, and it was only out of deference to the wishes of her mistress that she submitted to be revaccinated.

I inserted the lymph (humanised) in three places, telling her at the same time that I scarcely expected any result, as she had already had the disease. On March 29th she presented herself to show me the result, and, to my astonishment, I found that all three insertions had taken perfectly, and had resulted in good Jennerian vesicles, surrounded by a well-marked areola.

On inquiry she told me that she had had the same symptoms as when she had the cow-pox—viz., headache, nausea, and vomiting on the fourth and fifth days, together with loss of appetite and general malaise, but that now she felt much better. I hitherto understood that one who had had natural cow-pox was insusceptible to vaccine lymph from the human subject, and for that reason I write to ask of your numerous readers if they have met with similar cases.

I will only add that it is with great regret that I notice a growing prejudice against vaccination, which I by no means share, but, on the contrary, I have seen good proof of its capability of either preventing or modifying an attack of small-pox.

I am, Sir, yours respectfully,

St. George's-road, S.W., April 5th, 1881. J. H. Battye, M.D.

ALEXIS ST. MARTIN.

MANY of the readers of THE LANCET will recollect the remarkable case of this patient, whose chest was shot away, leaving a large opening into the stomach, and the observations on digestion made by the late Mr. Beaumont, of Toronto, and by physiologists in this metropolis. The poor man has just died, in great distress. For the sake of science it is to be hoped his stomach has been preserved, and may find a place in the museum of the College of Surgeons.

Junius.—The question is one of considerable difficulty and delicacy. The intermarriage of cousins is a subject which has not yet been adequately discussed or fully investigated, although a great deal has been written on it. In the case submitted, supposing there is a hereditary taint in the family, it would certainly be intensified, and the difference in age would probably contribute to that untoward result.

One of Them.—We regret to learn that the statement referred to was incorrect. We have every reason to believe it was made in good faith. It does not appear worth while now to reopen the question.

TRANSVAAL WAR—NATURE OF THE BULLET WOUNDS INFLICTED BY THE BOERS.

To the Editor of THE LANCET.

SIR,—I should, in conjunction with many of your readers, feel interested in any account which the surgeons with our Transvaal forces could afford of the nature of the wounds sustained by those slain or injured in battle. The curiosity aroused on this score is considerable, for rumour says that the bullets used by the Boers were of a kind forbidden by the Geneva Convention, being long in proportion to their rather narrow diameter from side to side, and hollow. Through this peculiarity of shape a horrible wound is the result. The projectile enters, making a small hole, but immediately flattens out like a medal, and at its exit leaves a large ragged opening. The question is, is the rumour correct in respect to the use of such bullets? If so, a few surgical accounts would be desirable.

I am, Sir, yours faithfully,

London, March 28th, 1881. H. R. OSWALD, M.B.

FUNGOID ORIGIN OF EPIDEMICS.

DR. MICHAEL W. TAYLOR has been lecturing before the Keswick Literary and Scientific Society on the Fungoid Origin of Epidemics. The lecture has been published, and the society may be congratulated upon the opportunity which has been afforded them of listening to so admirable an account of the present state of the question, both in its scientific and practical aspects.

Surgeon-Major John E. Purdon.—We think an article of the kind mentioned would be hardly suitable for our pages.

Mr. Thos. Horne.—The letter has unfortunately been mislaid. Will our correspondent kindly repeat his question.

Scrutator.—As the letter has already been published, we regret that we cannot depart from our rule by reprinting it.

PROFESSIONAL COMPETITION.

To the Editor of THE LANCET.

SIR,—Will you permit me to place before the profession, through the medium of your journal, the following letters, which have been sent by a neighbouring surgeon to the committee of one of my clubs. The only remarks I desire to be allowed to make upon them are: (1) the word "candidate" in the application implies a misapprehension on the part of the writer, there being no vacancy—real or contemplated; (2) I have held the appointment seven years, my house is about half a mile from the ironworks, and I live in the midst of the workmen, whilst the volunteer for the appointment lives two and a half miles away.

I am, Sir, yours obediently,

Alfreton, March 28th, 1881. THOS. WOLVERSON.

[COPY.]

Alfreton, March 15th, 1881.

DEAR SIR,—Will you kindly place the enclosed application before the Committee of the Alfreton Ironworks Sick and Accident Club.—Yours faithfully, T. L. ROBERTS.

To the Secretary.

Alfreton, March 15th, 1881.

GENTLEMEN,—I beg leave to offer myself as a candidate for the appointment of surgeon to the Alfreton Ironworks on the same terms as at present. In case I do not get the whole appointment, may I be allowed to attend those men who may give me their votes?

I am, yours obediently,
T. L. ROBERTS.

To the Committee of the Alfreton Ironworks Sick
and Accident Club.

EXAMINATION AT THE ROYAL COLLEGE OF SURGEONS.

AT the Primary or Anatomical and Physiological Examination for the Membership of the College, which was commenced on Friday last, there were 214 candidates, against 173 in the corresponding period last year. The following were the questions submitted to the candidates at the written examination on Friday last, when they were required to answer four, and not more than four, out of the following six questions on anatomy, between 1 and 3 o'clock:—

1. Describe the second cervical vertebra.
2. Describe the greater and lesser sacro-sciatic ligaments. What foramina do they respectively assist in forming? What structures pass through these foramina?
3. Describe the rectus abdominis muscle, and the sheath within which it is contained. How is it supplied by bloodvessels and nerves?
4. Describe the parotid gland and its duct. Enumerate the structures with which they are in relation.
5. Describe the lateral ventricles of the brain.
6. Give the dissection necessary to expose the course and distribution of the posterior interosseous nerve.

The following were the questions on Physiology, to be answered between 4 and 6 o'clock:—

1. Describe the minute structure and the action of the auriculo-ventricular and semilunar valves of the heart.
2. What is the normal temperature of the human body? Within what limits does it vary physiologically? How is it kept within these limits?
3. What are the functions of the roots of the spinal nerves? By what experiments have these functions been determined?
4. Describe the minute anatomy and the mode of action of the œsophagus.
5. What is the evidence of the existence of a respiratory centre in the medulla oblongata? How is this centre excited to action?
6. Describe the varieties, the microscopic appearances, and the uses of yellow elastic tissue, and state where these varieties are chiefly found.

As usual lately the provincial students were allowed to offer themselves the first three days.

COTTAGE HOSPITALS.

K. Z.—Cottage hospitals are highly approved, but they should be carried on jointly by the medical practitioners of the locality, and all financial matters should be worked independently by a lay honorary secretary. The medical staff ought to have nothing to do with the collection of subscriptions, but they would do well to retain the administrative government of the hospital in their own hands.

MEDICAL MEN AND RAILWAY COMPANIES.

To the Editor of THE LANCET.

SIR,—I shall feel obliged by an expression of opinion as to who is liable to pay my fee for attendance under the following circumstances:—On the 10th of August last I was summoned by an official of the London, Chatham, and Dover Railway Company to be in attendance at one of their stations to meet a certain train, a telegram having been received that in consequence of a passenger having died in the train on the journey from Ramsgate the attendance of a medical man was required. I attended immediately, and on my arrival at the station found that the train had just started. The station-master, however, stopped it, and requested me to accompany the deceased to Holborn. This I did, and superintended the removal of the body, which was done by one of the company's own vans. I was conveyed to and from Holborn without payment of fare. I of course considered that my services were rendered to the company. Upon making application for my fee of one guinea, which I consider moderate for two hours' work, I am informed by their secretary that the company do not consider themselves liable. They, however, sent an inspector to the relatives of the deceased, who procured from them the sum of ten shillings, which he brought to me as payment in full.—I am, Sir, yours, &c.,

March 23rd, 1881. M.D.

"SOME OBSERVATIONS ON BRITISH MINERAL WATERS AT THE PRESENT TIME."

To the Editor of THE LANCET.

SIR,—Your correspondent, Dr. F. William Smith, is moving in the right direction. The valuable mineral waters of Great Britain are in danger of being neglected in favour of the by no means more efficacious Continental waters. I would ask him to add to his list the waters of the Dunblane Mineral Springs, Perthshire. At the beginning of the present century these springs were very fashionable, and the waters proved to be extremely beneficial. The water is saline, and allied to the Airthrey waters. In order to develop the use of the springs they have been recently acquired by the Dunblane Hydropathic Company, and a suitable pump-room has been fitted for their use.

I am, Sir, your obedient servant,

March 29th, 1881. R. M. J. BANNING, M.D.

APPOINTMENTS AND REAPPOINTMENTS.

Medical Officer of Health.—Our correspondent who appeals for sympathy on the score that, having done his duty well and apparently to the satisfaction of the sanitary authority he serves, the time of his re-election approaching, and he having reason to believe that he would be re-elected, the authority have thrown the election open to the world, has not quite realised the fact that so long as the sanitary authority are acting within their legal rights, appeal to either public or professional opinion is hopeless, and can only end in injury to himself. It is distressing to think that the *esprit de corps* of the profession is so imperfect that members can be found who will take advantage, to the prejudice of a brother member, of opportunities such as those given by the sanitary authority in question, but the fact must be recognised.

SIMULTANEOUS ARREST OF RESPIRATION AND THE HEART'S ACTION DURING THE ADMINISTRATION OF ETHER.

To the Editor of THE LANCET.

SIR,—During the past few months there has been considerable correspondence in the medical journals upon the relative merits of chloroform and ether in the production and maintenance of anæsthesia. Whilst the matter is still an open question with the profession, I am of opinion that not only should deaths occurring during the administration of these anæsthetics be recorded, but also all cases in which any untoward accidents has occurred, and those cases in which death has been averted by mere good fortune.

The following case happened to me a few days ago. Though recovery took place, I must confess it was a very near shave of being a great deal worse. I am the house-surgeon (the only one) of a provincial infirmary. On March 10th an old man of seventy presented himself with a dislocation of the left shoulder. It appears the accident occurred to him some five weeks before, and the surgeon who attended to him had never reduced the luxation. The man was fairly robust, with moderately firm muscles. It is an understood thing in this institution that the house-surgeon should not administer anæsthetics when alone except in cases of emergency. Not being a written rule, and at times very difficult to carry out, it has been constantly ignored. On this occasion, failing to reduce the shoulder by ordinary methods, I had the man put in bed, and gave ether from an Ormsby's inhaler as modified by Clover. Two nurses were at the bedside with me. The patient was unconscious, with relaxed muscles in four minutes; breathing and pulse both regular when I ceased to apply the inhaler; the shoulder was easily reduced by placing the heel in the axilla. A nurse took charge of his arm to prevent any movement during the period of recovery. I placed myself at the head of the bed watching the respiration and pulse at the temporal artery. Soon after the pulse and respiration ceased simultaneously, immediately previously having been regular. The patient became quite leaden in colour. I at once seized the arms and carried out artificial respiration by Silvester's method. I despatched one nurse for the battery and the other for a jug of water. As ill-luck would have it the battery was then in use in the out-patient room, and the jug on the ward-table was empty. These circumstances caused delay. I continued the respiration; water was dashed over the head. Just after I had the satisfaction of seeing a spasmodic gulp made by the man. The battery was now applied to the diaphragm region. Another gulp followed, and gradually recovery and consciousness took place. This case has been a warning to me. Though I have administered both ether and chloroform many times and often by myself, I have never fortunately had an accident. Should this note meet the eye of any house-surgeons, let them be only too careful not to relax their vigilant watch over the patient until perfect recovery has occurred, for in this case the accident did not occur soon after the commencement of the administration, but at the time when we were expecting the patient to waken, and some five minutes after the inhaler had been removed.

I am, Sir, yours faithfully,

March, 1881.

R. H. F.

CAMBRIDGE UNIVERSITY.

OWING to great pressure on our space we are compelled to defer until next week the notice we had prepared of the important statutes made by the Cambridge University Commissioners, and submitted for the approval of Her Majesty on the 1st inst.

M.R.C.S.—The "internal capsule" is the tract of white matter between the optic thalamus and the lenticular nucleus of the corpus striatum, and is composed of fibres passing from the lower part (crusta) of the cerebral peduncle.

Dr. Macewen (Glasgow).—We shall be glad to receive the paper.

Dr. Caton.—We shall be glad to see the "parts" as issued.

Mr. H. G. Sutton.—The great majority of the profession are in accord with our correspondent in the matter.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Fenwick, London; Mr. Fletcher, Warrington; Mr. Pearson, London; Mr. Spratt, London; Mr. Craigie, London; Mr. Tripp, London; Messrs. Boyle and Son, London; Mr. Sawyer, London; Dr. A. Mackintosh, Chesterfield; Mr. Leeming, Kendal; Dr. Decroix, Paris; Dr. J. W. Bramwell, Newcastle-on-Tyne; Dr. Fisher, London; Mr. Sutton, Sittingbourne; Mr. B. Squire, London; Mr. Barnard; Mr. P. Thornton, London; Dr. Mahomed, London; Mr. Mackellar, Poona; Mr. H. J. NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

Croonian Lectures
ON THE
INFLUENCE OF THE CIRCULATION ON THE NERVOUS SYSTEM.

Delivered before the Royal College of Physicians of London,

BY WALTER MOXON, M.D. LOND., F.R.C.P.

LECTURE II.—PART II.

If, indeed, we cannot prove by post-mortem examination that a person has died from congestion of the brain, the evidence which would lead us to declare the existence of such a state during the person's life ought to be the more conclusive. Let us now inquire if this is truly the case. I have already asked your attention to the degree of turgescence of the veins of the head and face, indicating a like degree of pressure within the veins of the cranium which is met with frequently under various circumstances, and which does not give rise to serious or important symptoms; strangulation becomes very decided and obvious before any serious cerebral effects result from it. Hence we must not suppose or assume its presence unless we can see the veins evidently turgid, and although total stoppage of the jugular veins by ligature will produce speedy death, yet inasmuch as we thereby deprive the brain of its blood circulation so that life ceases with the cessation of vital changes in the respiratory centres, we have here a set of consequences which ensure death apart from pressure of venous blood upon the brain. Indeed I have never met with any example in which venous pressure upon the brain, as distinguished from the effects of carbonic acid poisoning, has produced grave symptoms. And I advanced the example of caisson pressure as affording an instance of extreme degrees of intravascular pressure of blood upon the nervous centres, uncomplicated with a venous state of the blood, and it was shown that under a pressure of three atmospheres continued for as many hours, no unpleasant results were experienced, so far otherwise, indeed, that the labourers worked more buoyantly in the denser air. It was when the pressure was taken off that trouble came. As one more example to show how well an obvious amount of arterial pressure is borne by the brain, let us take the case of unusually violent action of an hypertrophied heart. It is not, of course, to be supposed that in all or most cases of cardiac hypertrophy an excessive action of the heart would tend to congest the brain, because for the most part the heart enlarges in order to overcome an obstruction at its orifices or an obstruction in the capillary system. In these cases the hypertrophy does but follow after, and usually far after, the requirement which it subserves, and the large labouring heart is all too feeble for its extra work. But we meet occasionally with more rare examples wherein a large heart certainly does appear to exert an exaggerated force throughout the vessels. A striking example of this is in the clinical ward at Guy's Hospital, in the case of a man of early middle age who has regurgitant aortic valves and a very greatly hypertrophied heart, which raises the præcordial region, and in its beating shakes forcibly the lower part of the chest. The innervation of the heart is here deranged as if by a touch of exophthalmic cachexia superadded, for the heart's action is very rapid, and digitalis in any doses I dare give shows no power of reducing its frequency. The effect of all this in the temporal and radial arteries is remarkable; they are bent into a meandering form and are tense to touch, each beat of the heart making them spring rather sharply. Those who witnessed the force evidently at work within these arteries, and conceived the same action as going on within the cranium, formed the impression that the arterial strain must be excessive there, allowing all that the bend of the carotid canal could do to moderate the distension of the arteries in their transmission through the base of the skull. Yet this man said that his head was quite free from unpleasant sensations, and when I induced him to cough and otherwise to use strong pressure of his expiratory muscles so that the veins rose in his neck, the heart beating meantime still more strongly and quickly with his exertion, no ill effects occurred in the way of morbid sensations in the brain. This example is not a very rare one, although the coexistence of rapid action of the heart with great hypertrophy and absence of evidence of aortic obstruction offered a combination calculated to put great stress upon the interior of the vessels, and the strain was visibly great in the superficial arteries. Indeed, under similar circumstances, especially in cases of exophthalmos, we witness an extent of more or less violent and certainly obvious over-action in the cervical vessels, producing no noticeable discomfort in the brain, and certainly nothing in the nature of serious and important symptoms.

So that, as we pass to consider what clinical evidence there is to show that serious and important diseases are due to cerebral congestion, we do so having first recognised that visibly forcible arterial action does not produce these symptoms, and visibly great venous congestion does not produce them, and post-mortem evidence is incapable of proving that cerebral hyperæmia was present before the act of dying. Still pursuing the question before us, the next thing will be to learn what evidence is offered in the symptoms ascribed to cerebral congestion to show that fulness of the cerebral blood-vessels causes the attacks described under that name. If we look at the descriptions of the supposed disease, we find it has all the advantage of being well portrayed by the best describers, including a most trustworthy and universally trusted authority upon the subject of brain diseases in general, so that we may fairly assume that all that can be said for the disorder is well and fully said. The disease would merit such treatment if it is indeed capable of appearing in no less than four distinct and very widely diverse manifestations, and if in each of these it may constitute an obscure and rapidly fatal malady. The symptoms of such a disease must merit the closest attention, and so I may ask you to let me now give a full account of the symptoms described as those of one of the forms of congestion of the brain; it is called the convulsive form, and these are the symptoms given: "There are usually the premonitory signs of congestion, but these may be very slight. There may be no forewarnings, and the patient may be seized during sleep or while making some unaccustomed effort. When the attack occurs during sleep, it is difficult and sometimes impossible to say in what manner it commenced; but when it has come on while the patient is awake, and friends are around him, it has been usually observed that much discomfort has preceded it for a few seconds, minutes, or hours. A tight cravat worn while making undue exertion, a sudden alarm, or an indigestible meal rapidly swallowed, may be the immediate antecedents. The patient more or less suddenly becomes confused, then apparently half unconscious, makes some unintelligible sounds, turns red and then blue in the face, staggers for support, looks round him wildly and imploringly, and then sits down or falls down convulsed, and a paroxysm epileptiform in character supervenes. From this he recovers partially, exhibiting great confusion of mind, headache, muscular feebleness, and sometimes partial paralysis of one side or of one limb. The attack is occasionally followed by quasi-maniacal excitement lasting from half an hour to three or four hours; after which the patient becomes exhausted and falls into a heavy sleep. From this state he may recover, or during sleep a second or third attack of convulsions may come on. When congestion of the brain has assumed this convulsive form, the patients, so far as my own experience extends, have usually been in middle life and have recovered. But in other cases, when the age has been further advanced, the attacks have recurred more frequently, the intervals between them have become of shorter duration, and the patients —less sensible and less reasonable after every paroxysm— have presented the appearance of those whose attacks have been apoplectiform at their commencement." This description, coming from the pen of a masterly describer, puts vividly before us the condition depicted, but that condition appears so exactly like epilepsy in a plethoric person that one is rather puzzled to detect a difference between this convulsive form of congestion of the brain on the one hand and epilepsy in such a person on the other, and one gladly turns for guidance to the directions for diagnosis, which tell us that "from epilepsy the diagnosis may be made by a consideration of the previous history; in the one there have been the premonitory symptoms of congestion of the brain; in the other no such phenomena have presented themselves;

in the former the patient is usually of middle or advanced age, in the latter he is young and is either under twenty years of age or has not far exceeded that period of life; in the one the period of most marked congestion is at the moment of seizure, in the other congestion of the face and head is most marked as the attack is passing off; in the former there may be some moaning sound, in the latter the epileptic cry; in the one there is the sudden onset of an acute disease, in the other the attack of a chronic malady." Thus it appears that the points of distinction in the attack are the middle or advanced age of the patient, the comparison of the colour of his face in the beginning and in the subsequent course of his fit, and the moaning sound in congestion as compared with the "epileptic cry" in epilepsy.

As to the latter point we, however, find the same distinguished authority speaking thus, in an admirable description of epilepsy itself: "Others do not cry, but emit a moaning sound, which is, as it were, squeezed out of them by the quasi-tonic contraction of the muscles of the chest." So that the moaning sound does not help us if we bear in mind the account of true epilepsy. Again, as to age, the same full and excellent account of true epilepsy informs us that a considerable proportion of first attacks occur about the fortieth year of life; so that the age of the patient would appear to be no valid criterion, and then the only thing remaining is the play of colours in the patient's face during the fit. Thus the convulsive form of congestion resolves itself into an attack which is exactly like epilepsy, except in the plethoric appearance of the patient. But are we, then, to suppose that plethoric persons don't have epilepsy? If this is not the supposition, how are we to deal with the case of a red-faced person who should have a true epileptic fit? How should we distinguish between such an attack and an attack of congestion of the brain? One looks in vain through the description for any criterion. There are all the stages of epilepsy—the bluish tinge appearing on the red of the face, the groan, the fall, the struggle, the stupor, and even the final, perhaps almost maniacal, excitement at the close. Even the tight cravat and the full meal which appear in the description of congestion do not really help us, because the true epileptic might have on a tight cravat or might have had a full meal. The evidence, then, of congestion of the brain is utterly worthless, unless you assume that plethoric persons do not have epilepsy, and that after a full meal or in a tight cravat epilepsy is not epilepsy. But the question whether such persons have epilepsy is not even raised by the description which changes the whole fundamental pathology of the seizures, because the sufferer's face is red, and he has just had his dinner. I have quoted from the writings of one who is so entirely master of the subject of nervous diseases that the evidences in favour of congestion of the brain would certainly all be fully and fairly stated in his description of it. Yet, surely, we have seen but very trivial ground for raising the convulsive form of congestion of the brain as a distinct kind of disease; and we further have even some proof of a positive kind to show that you cannot judge of the amount of blood in the brain by the amount of blood in the face. At least in sleep we know the brain to be pale. Yet in sleep the face is more congested than it is under ordinary conditions when awake. If you look at a sleeping person you may commonly observe everywhere about the head signs that would show congestion. The contracted pupils, the suffused conjunctiva often causing an excess of secretion from the mucous surface, or the well-known puffy state of face and eyelids found in the morning in cases of Bright's disease and other conditions. The reddened and perspiring state of the skin, conspicuous in many people in deep sleep, and often wetting the pillow in phthisis. Yet, in spite of all these signs of congestion outside the cranium, the brain within it is shown to be pale in sleep. So far, then, from redness of face proving congestion of the brain, the best known instance bearing on the question shows the brain to be paler when the face is more congested than the average.

The importance of the question whether, as asserted in some text-books, disease and death are really due to a rush of blood into the vessels of the brain, or whether, as I believe, no serious symptoms or ill results are produced by blood rushing into or pressing within the bloodvessels of the brain, will, I trust, justify me in pursuing the examination of the asserted symptoms of cerebral congestion, still searching for evidence that these symptoms are due to congestion of the brain. Yet as to the form of the disease that is called apoplectiform cerebral congestion, I will not go into detail, because the kind of attack of sudden insensibility which has long been known by this name has been so thoroughly treated of by the late Professor Trousseau, and by him was so entirely well proved to be really epileptic, that I need only refer for evidence to Trousseau's lecture upon the subject. In that lecture he says: "During the first years of my practice I saw a pretty large number of cases of apoplectiform congestion; but for a long time I have not seen any. Yet other medical men see as many as before. Let us therefore inquire on whose side the error lies." And then he gives proofs of the epileptic nature of such attacks, which I think so convincing that they need only to be read to clear up any doubt upon the matter. It is perhaps due to Professor Trousseau's influence that the most modern English teaching is coming round to the same view, as shown in the most recent and one of the best of our text-books, in which we find it written: "The true apoplectic attack in which the patient falls down suddenly comatose is now generally admitted to be epileptic." As a small further contribution to the previous evidence upon the epileptic nature of apoplectiform cerebral congestion, I will only point to one feature in descriptions of the attack, and that is, "the pulse at the moment of attack is sometimes suspended at the wrist." Of course it is plain that suspension of the pulse would not be likely to produce congestion of the brain, and, indeed, it is clear that suspension of the pulse must cause anæmia of the brain. But I will bring forward some facts in my next lecture which will, I trust, show that suspension of the pulse accompanies and marks the onset of attacks of epilepsy, and is the cause of paleness of the face in the epileptic onset. I need hardly say that the question at issue is one that practically is important. For if the attack is epileptic it calls upon us for remedies and regimen such as reduce the general excitability of the nervous system, and especially for specifics such as potassium bromide. But if the attack is indeed congestion of the brain, then it calls upon us for local treatment of the head more or less of the nature of depletion.

If we seek in the two remaining forms for evidence that the disease is really due to congestion of the brain, we are met with proof to show that the contrary is really the case. The characters of the third or "febrile form" are those of an attack accompanied by marked elevation of temperature and general pyrexia, dull oppressive headache, &c. Recovery is said not always to be observed. "The distress may persist, there may be alternately convulsions and delirium, or there may be changes from over-excitement to drowsiness, the latter gradually becoming relatively more marked until the patient passes into a state of stupor from which he may never rally." Now, if such a group of symptoms were to come upon a healthy person it is a fair question whether the medical attendant would be well advised in resting satisfied with an opinion that the case is one of congestion of the brain. If the attack ended fatally would he not have to inquire which of the eruptive fevers, or what form of blood-poisoning, had seized and killed the patient without allowing time for the development of the distinguishing characters of the attack? In every case in which I have known a healthy person fall into febrile coma, that person has proved to be suffering from a definite disease which needed to be discovered. For example, a little girl at Tottenham, having precisely these symptoms, was said to die within twenty-four hours of "congestion of the brain." Scarlet fever appeared in her sisters within twenty-four hours more, showing what was the matter. A man approached very near to death, being quite comatose, with elevated temperature; he then developed a most profuse urticaria, and forthwith recovered; had he died we should not have known better, perhaps, than to have called his disorder cerebral congestion. Such instances might be multiplied indefinitely. I am ready to admit that such a term as congestion of the brain is useful to the practitioner in some of his difficulties, and so far as it is understood to signify only that the case to which it is applied is cerebral and obscure, there is no harm in it—nay, there is a certain advantage in its indefiniteness—whilst it meantime does not usually carry an unduly sudden or alarming impression to the minds of the patient's friends. But, for all this, it is surely undesirable to make this conveniently vague term take a place in strict medical teaching, and to use it there as covering several widely diverse, disordered states, which can be only very vaguely portrayed even by our best clinical describers, seeing that there must arise a great temptation to stop at this idea of congestion of the brain when further inquiry would have shown the real nature of the case. It is true that we are compelled to use some terms to give expression to all that we can know of obscure disorders, and it might be thought that "congestion of the brain" stands thus on a par with "sciatica" and "colic." But there is a wide divergence between these, at first, apparently parallel examples. When a person has pain in the course of his sciatic nerve we search for aneurism or other tumour which might cause the pain, and if we do not find any such cause we say the case is one of sciatica. Even here there is a danger of our too easily taking up with the easier diagnosis of sciatica, a danger which not unfrequently induces the practitioner to overlook an organic cause of pain. However, there is nothing wrong in describing pain in the course of the sciatic nerve as sciatica, since the term means only sciatic nerve pain. Likewise, in the case of such an expression as colic, the term applies without doubt, whatever be the nature of the colic pain. The term involves no supposition of a definite cause of the complaint, and there is nothing positively misleading in the use of it. But in the example of "congestion of the brain," employed in a similar vague way, there is this important difference, that the term does signify a fulness of and pressure of blood within the cerebral vessels, which fulness and pressure may not exist, and I think I have shown probably do not exist. So that whereas in any prepossession with the idea of sciatica we only incur the risk of sometimes failing to reach the whole truth of individual cases, we are probably entirely wrong at all levels when we use the term congestion of the brain. Again, this term does not only apply to one definite kind of pain like sciatica and colic, but it is made to include convulsive disease, apoplectiform disease, febrile disease, and mental aberration, thus extending its shadow and obscurity to confuse a very large part of the otherwise clear history of diseases of the brain.

We could not perhaps have a better example to show how far the description of these diseases as congestion of the brain is correct than we meet with under the form I am now discussing—the febrile form of cerebral congestion; for we see the whole group of symptoms described as the febrile form of cerebral congestion appear as "cerebral rheumatism" in rheumatic fever. Now, in cerebral rheumatism with its perfectly characterised febrile congestion of the brain, we happen to have very decisive evidence that there is no congestion of the brain, but the exact opposite of this. Ten years ago one did not know what to do with the rapidly fatal brain symptoms which occur in some cases of rheumatic fever. I tried bleeding, and large doses of brandy and large doses of quinine, but all the patients died. The plan now successfully adopted is well known. I first practised it in 1870, and an account of the case was published by Mr. De Liefde, then house-physician. I mention it because of the somewhat rude thoroughness of the treatment. The patient had passed through the stage of muttering, delirium, and was settling into insensibility, when at a temperature of about 106° he was put at once into cold water at 60°. The result was that this almost comatose and dying man shortly became as sensible as any of the bystanders. Now the effect of such a sudden plunge into cold water must be to drive blood from the surface of the body to the deeper parts, including the brain. Indeed, the treatment is the extreme reverse of that putting of the feet and hands into hot water, which is recommended for cerebral congestion. Yes, doubtless rightly, and if you placed the feet and hands in hot baths, you must tend to draw blood away from a congested brain, and *per contra* by placing not only the feet and hands but the whole body in very cold water you must tend to do the opposite of this and drive blood to the brain. But in this case in which every symptom described as cerebral congestion was at its highest degree and on the point of a fatal issue, the extreme reversal of the treatment for congestion, this driving of blood to the brain wakes up the man in the most magical manner.

Thus the third form of so-called cerebral congestion belies this view of its nature by passing off under treatment, which must add to any congestion really existing in the brain. Let us now look at the last of the forms of so-called cerebral congestion, that noted as delirium. The description is of a patient of advanced age, who after some hours or even days of undue taciturnity becomes cheerful, or gay, or hilarious; he talks loudly and incoherently, but rarely exhibits any violence. He gets out of bed, wanders about his room or ward, opens drawers, puts on his dress, and is bent upon doing something which he cannot explain, or which if expressed in words is unnecessary, unaccustomed, and absurd. He is under a delusion of no fixed character, and can usually be directed and controlled without much difficulty. This being the description of the ailment, it may be well to see how far it is a good thing to teach it as a sufficient view that such symptoms are due to congestion of the brain by giving shortly the history of a case of the kind. Not many months ago I was asked to see an elderly man whose relatives were said to be quite worn out with taking care of him on account of his insane conduct. The medical gentleman in charge of his case said that the disorder was congestion of the brain, a bodily disease, and not mental, so that he refused to certify to the patient's insanity. When I saw the man I found a state of affairs completely justifying this view according to those who teach of a delirious form of congestion of the brain. Mr. P—— was fifty-nine years of age. The poor fellow had been knocked down and robbed two years before, and of late he had shown great depression of spirits. Then he grew excited and talked, and was pleased at the idea of going home. He got out of bed and wandered about his room, and opened drawers, and dressed himself in the middle of the night, and wanted to go home through the second floor window or over the balustrades of the stairs. But there was no fixed character in his delusion; sometimes he was content to stay where he was under the idea that the Queen had made all the days Sundays now. He was generally submissive too and managed without any difficulty except the fatigue of constantly watching him. He had his wandering attacks almost nightly between September and December. This man's disorder corresponded in all points exactly with the so-called delirious form of congestion of the brain. So that the medical practitioner in attendance, trusting his look, was justified in saying that the man had congestion of the brain and not insanity. But meantime this madman was endangering his own life very seriously, and causing the gravest overstrain to the members of his family, who were unequal to the care of him. Certificates were immediately signed and he was put into comparative security, from which the entirely baseless theory of congestion of the brain was keeping him through the accurate knowledge the doctor had of his teaching. I think one may say, without prejudice, the utterly baseless theory of congestion of the brain. Such excitement does not show congestion of the brain. The best marked cases I have seen of this kind of insane delirium have occurred in heart disease. "Yes," it may be said, "exactly the condition to congest the brain!" But no one would say that if he were to bear in mind the kind of hydraulic difficulties that affect the circulation in heart disease. It is true that in heart disease you have congestions enough. But the congestions occur in the dependent parts of the body, because the inanimate power of gravitation takes hold upon so much of the blood as a weak heart cannot drive, and draws so much blood downwards; but in doing so it draws away from the head and other upwardly-disposed parts of the body, which are thus kept empty in proportion as the dependent parts are full. And, indeed, in a severe case of delirium which occurred in a man with cardiac dropsy in Philip ward of Guy's Hospital I put the matter to a severe test. The miserable man, after weeks of breathlessness and sleeplessness, became insane, with the symptoms I have read to you as those of cerebral congestion. I had his pillows taken away, and kept him asleep with chloral for three days; at the end of that time he was allowed to wake, and he was then quite sane again, and he afterwards recovered so far as to lose his dropsy and leave the hospital. I believe that if I had kept his head high he would have died. The symptoms were those of an exhaustion in an anæmic brain.

Indeed, the circumstances in which cerebral excitement appears are so far from being of a kind to show an exaggeration of the powers of the circulation that, from this point of view, we can only wonder how it has come to pass that excitement of mind occurring in the aged, the exhausted and the dying, is as generally interpreted as signifying an excess of circulation in the brain. The reason, doubtless, is on account of the natural way in which we infer from the violences set up by a disturbed mind that a like violence must be at play in the brain as the organ of the mind. It is so natural to suppose that activity of the eye, and tongue, and hand must mean activity of the circulation which feeds the nervous centres of the eye, and tongue, and hand. It is thus that the sight of overactive mental states brings to the medical mind the idea of too great fulness of the bloodvessels as naturally as the sight of the diurnal course of the sun in the sky brings to the popular mind the idea that the sun goes round the earth. In either case it is only by further consideration that the fallacy of evidence so apparently obvious is made certain. Reflection will show that the activity of these delirious persons may be negative, because it may take its rise through a want of the adjustment of balance of self-restraint which a good circulation in a healthy brain gives rise to. And the aged and exhausted state of the sufferer point directly to such a negative cause. Whilst the treatment also must recognise the negative condition, and do all that can be done to feed the brain and support the system. The decisive style employed by specialists in brain disease in their pathological descriptions has done much to encourage the widely spread delusion as to congestion of the brain. The diseases such as acute mania, for which they seek the anatomical causes, offer a most impressively violent and active behaviour of the brain, and so little appears post-mortem, except perhaps a full condition of bloodvessels, that the temptation to dwell upon this state of fulness and make much of it has proved irresistible even when a reasonable doubt of the importance of congestion has forced itself upon their notice. Thus one of the least conventional of brain specialists, Griesinger, after allowing that in his first edition the significance of hyperæmia had been greatly exaggerated, goes on nevertheless with really unabated confidence to assert the usual fallacies. First he says, that from the changes found after death, increased fulness of the vessels during life is to be assumed. "To this, therefore, a certain connexion with the morbid state is to be ascribed." An obvious fallacy, if by a certain connexion he means a causative connexion, and unless he means a causative connexion his remark has no meaning at all. He then goes on to give the usual worthless account of redness, &c., of the brain, which I have already sufficiently discussed, and ends by saying, "this hyperæmia may easily pass into actual inflammation," a thing which it is utterly impossible that any one could know. The fact is that the notion of a flooding of the brain with blood is always ready for use, so that it can be drawn upon by anyone in difficulties for an explanation. And thus if the alienist needs something to stand for a cause of violent mania, it is congestion of the brain. If the practitioner in charge where head disorders do not include madness wants an explanation of seizures that are the exact reverse of mania—fits in which, instead of violence, you have oppression and stupor,—he has it, it is congestion of the brain. If the question is of some "wiry old person"—the expression is not mine—whose circulation is, one would think, too poor to congest anything, if this old person shows negation of brain activity, still it is congestion of the brain. If a person has drunk enormous quantities of alcohol, and is comatose, this, too, is congestion of the brain; and if he has been out in the sun and has a cerebral seizure, this too is congestion of the brain.

I suppose there must be a certain satisfaction in exchanging the obscurity that beclouds our ideas of disorder of the nervous system, of whose order we know so little, for a disturbance of the hydraulics of the blood, about which we can know much more. Even though the result is only a translation of the terms in which the symptoms are interpreted to the mind, rather than an explanation of the symptoms. There is, indeed, no true explanation attempted, for no one who asserts that congestion of the brain causes mania is able to say at all what causes the congestion of the brain.

I have thus far endeavoured to establish these propositions :—First, that atmospheric pressure so great as to force blood into the vessels of the brain more thoroughly than could be done by any intrinsic forces of the circulation does not produce cerebral symptoms. Second, that strangulation and carbonic acid poisoning lend no support to a supposition of independent congestion of the brain. Third, that morbid anatomy is unable to show any evidence of general overfilling of the bloodvessels of the brain. Fourth, that in the diseases described as congestion of the brain clinical evidence of overfilling of the cerebral bloodvessels is utterly wanting, and that the state of circulation present in these disorders can be shown in typical instances to be the reverse of an overfulness. From all this it follows that there is no pathological justification for our setting up congestion of the brain as a distinct kind of disease, nor for our pretending to explain cerebral symptoms by the assumption of congestion of the brain. For the forcing of blood into the brain whilst the blood is good and properly aerated, and is within its vessels, affects only favourably the functions of the brain as far as our evidence goes. I cannot quite tell where or how the idea arose, but it appears to have been very anciently and naturally supposed that when the senses are lost or submerged this can only happen through their being drowned in the blood. But the example of sleep is contrary to this rough notion; for since Mr. Durham twenty years ago showed that the brain is pale in sleep, and other experimenters have confirmed the observation, we have a daily occurring analogy in every living person which would lead us to expect insensibility to occur with a pale brain, rather than with a brain loaded with blood. Again, fainting teaches us the same lesson : we see in fainting the senses pass into abeyance through bloodlessness of the brain. On the other hand, I do not know of a single proven example in which the senses are lost by pressure of blood within the vessels of the brain. If you object to this that strangulation gives such an instance; it must be remembered, on the contrary, that strangulation involves a stoppage of circulation and of all vital changes in the brain; and again that it must be very thorough to cause unconsciousness. So that strangulation has no bearing as a fulness of the vessels of the brain, whereas the caisson pressure gives us the most absolute proof that immense pressure of blood into the cerebral vessels only increases the comfort of the brain, and in fact shows that the brain is glad of blood, and the more the better, so long as it is good and does not burst the vessels. I shall now endeavour to point out that bursting of the vessels occurs only in relatively bloodless brains; and so apoplexy has no bearing in favour of congestion of the brain.

The theory of congestion of the brain has been taken from a too simple and superficial notion of the relation of the brain to its blood supply. If we take a primitive view of this matter and suppose the skull to be a closed cavity containing more or less blood, our course of thought would naturally run much in this way. Persons seized with sudden unconsciousness and dying are found to have an escape of blood within the brain which compresses it; and other persons attacked in a practically identical way show no such escape of blood. It is, then, in the absence of reasons to the contrary, easy and natural to suppose, as an explanation of all this, that in the cases where bleeding occurs the blood before bursting the vessels was pressing very severely inside them, and was distending them and filling the skull over-full, and squeezing the brain very effectually. With such an idea in the mind, it is further easy to think that when no bursting of the vessels occurs, this squeezing of the brain by blood in the vessels would cause the same results as the pressure of blood escaping from the vessels when they burst; and from this point of view it is even possible to regard the bursting of a vessel and the bleeding into the brain as a thing of secondary importance, and to believe that the apoplexy is really set up when a certain engorgement under pressure is reached, which pressure may or may not burst a vessel; but whether it does or no matters little, for the pressure on the brain is the same whether the blood is in or out of the vessels, and, indeed, this opinion has been held and openly stated. But such a line of reasoning overlooks or under-estimates the efficiency of the means whereby the cerebral circulation is relieved, and it overlooks the nature and consequences of arterial tension. And especially it overlooks the fact that apoplexy, when not the result of aneurisms of the cerebral arteries or of embolism of those arteries, is nearly always the consequence of the high arterial tension of Bright's disease, and is almost limited to cases of granular kidney and of hypertrophy of the heart.

I do not think that the considerations that arise from what we know of sanguineous apoplexy have been reflected upon the naïve and simple but plausible conception of congestion of the brain as this conception was formed by our predecessors. For with what we now know of the circulation, arterial, capillary, and venous, we may prove that the notion of a filling of the vessels of the brain with blood so that they compress the brain is unfounded so far as sanguineous apoplexy is concerned. The relations of apoplexy to Bright's disease, and through Bright's disease to high arterial tension, throw significant light on the whole of the subject, and prove that the bursting of a small cerebral artery and the consequent bleeding does not arise from any general vascular fulness in the cranium, but from tension in the arterial system only, which tension leads to the rupture of the vessel. Now, high tension in an artery means resistance to the flow of blood from it into the capillaries, and diminished flow through them into the veins. Hence we see that the high tension in the artery, which eventually bursts it, takes its rise in a cause which prevents supply of blood to the capillaries and veins, so that the higher tension in the arteries indicates a cause excluding blood from the far more capacious veins, and hence, in proportion as the blood is disposed to burst the artery, in just such proportion is the venous system underfilled. And, in fact, it thus happens that instead of blood bursting out in apoplexy through a general overfulness of vessels in the skull pressing on the brain, the vascular system, as a whole, is underfilled. And this is not a merely theoretical view, although I think the theory itself will stand any examination. But, in fact, before the consideration of the question from a theoretical point of view offered me this explanation of observed facts, I had observed that those brains in which apoplexy occurs carry signs of old anæmia, and indeed present the appearances characteristic of atrophy from deficient supply. I am not here speaking of apoplexy from such accidents as aneurism or embolism, but of ordinary apoplexy in elderly subjects ; and I believe it will be found true that the symptoms which give warning of coming danger, the giddiness and transitory numbness, &c., are evidences of capillary and venous anæmia of the brain, which is starving under the resistance offered to the entry of a due amount of blood. Thus, so far from an apoplexy being significant of a general filling to the bursting-point of the intracranial vessels, causing such a fulness under pressure as would compress the brain, it is only in the arteries which are small, and not capacious, that any excess of blood or rather excess of tension in the blood is present ; and the idea of a cranium crammed with blood which if it did not burst the vessels would equally squeeze consciousness out of the cerebral texture may be regarded as altogether mythical.

Gulstonian Lectures
ON
ANÆMIA.

Delivered before the Royal College of Physicians,

BY SIDNEY COUPLAND, M.D., F.R.C.P.,
PHYSICIAN TO THE MIDDLESEX HOSPITAL.

LECTURE III.—PART I.

Idiopathic Anæmia (continued). — Chlorosis: Reasons for and against its separation as a Distinct Disease — Congenital Defects (Vascular Hypoplasia, Virchow) cannot be at the root of all Cases—Its obvious Relations to altered conditions of Life and Work—Relations to Menstrual Irregularities—Symptoms those of Anæmia—The Blood in Chlorosis—Effects of Treatment. — Cardio-vascular Symptoms of Anæmia: Cardiac, Arterial, and Venous Murmurs; their Mode of Production—Anæmia as a Cause of Heart Disease (Goodhart).

MR. PRESIDENT AND GENTLEMEN,—In my last lecture I endeavoured to show that pernicious anæmia must be considered as the outcome of a severe anæmia, whether symptomatic or idiopathic, its progressive course and frequently fatal issue being induced by changes of which there is yet but little evidence either in the normal formation of the blood or in its destruction; and I propose to-day to speak in the first place shortly about Chlorosis, which I believe to be a form of anæmia depending on similar changes, and therefore to be considered as falling under the head of idiopathic anæmia. I know that this is contrary to prevalent teaching, and perhaps may be regarded as a retrograde step, for the tendency is undoubtedly rather to analyse diseases than to effect syntheses of conditions which have a superficial resemblance. But where the distinctions are so finely drawn and so subtle as they are in respect to chlorosis, such analytical severance is hardly justifiable, perhaps harmful, and certainly productive of confusion. There is only one certain ground for such severance, and that is the one which follows from Virchow's discovery in some cases of chlorosis of what appear to be congenital defects in the circulatory mechanism, to which I shall presently refer. Setting that aside, there does not appear any marked distinction between chlorosis, in its development and progress, from other forms of anæmia of idiopathic origin, save only that in many of the latter the progress is uninfluenced by treatment. The point of view taken by those who argue for the separation is that chlorosis is a distinct morbid entity, of which the anæmia is but a symptom[1]—that it is marked by nervous derangement, and frequently by menstrual disorder, as much as by anæmia. But the same may be said with equal warranty of the forms of anæmia to which it should be allied. The anæmia itself is only a symptom, which in its turn brings other symptoms after it; and in both chlorosis and in the idiopathic anæmia of the adult the anæmia prevails over every other symptom.

The reasons which, so far as I can gather, are advanced in favour of regarding chlorosis as a distinct disease are these: its almost complete limitation to the female sex; its apparent dependence in some way on the menstrual function, and the changes undergone by the organism at puberty; certain nervous conditions, and certain peculiarities in the composition of the blood, and the structure of the bloodvessels. I will consider each of these in turn.

It is well known that females are more readily influenced by anæmiating causes than males; the blood is less rich in hæmoglobin, and its quantity is less. Any influence liable to create a demand on the blood is more likely to lead in the female to anæmia than in the male; and not only at puberty, but during pregnancy, the puerperal period, lactation, and the menopause, anæmia may arise and become profound. There is no essential difference between the anæmia produced at any of these periods. Nor is the limitation to the female sex of a condition indistinguishable from chlorosis invariable. I have at present under my care a youth, well-developed and well-nourished, who is the subject of an anæmia conforming in its history and characters, and I may add in its curability, to the most typical cases of chlorosis, and from time to time such cases of male chlorosis are recorded. More than this, in later life the male like the female appears to be liable to the development of an insidious anæmia, without wasting, which in all its leading features resembles chlorosis. It may be initiated by the same influences, mental, physical, hygienic, and other, which initiate chlorosis; it is not so common or so frequent because in adult life the balance between blood formation and destruction is more evenly maintained.

The dependence of chlorosis upon the menstrual function is not so absolute as is often supposed. The importance of that function and of its regular continuance are doubtless great, and of considerable influence upon the blood; and at puberty there must be a considerable readjustment of the forces of the organism when the processes of ovulation and menstruation are established. There must be an increased demand on the blood then and at every recurring menstrual period; and although we may be unable to state precisely what the influence is, we are persuaded that there is a connexion between the normal evolution of the blood and of these processes. At the same time menstrual irregularities often neither precede nor accompany the development of an anæmia indistinguishable on other grounds from chlorosis; whilst both amenorrhœa and menorrhagia are as frequently secondary to the anæmic condition as initiatory of it.

The same might be said of those nervous symptoms which frequently predominate in chlorotics to such an extent that some have desired to place chlorosis among the neuroses. For whether we regard the mental and emotional characteristics, or the liability to neuralgiæ and other nervous disorders; whether we consider the influence of psychical perturbations in determining the development of the anæmia,—there is no firm distinction between chlorosis, as generally understood, and ordinary anæmia.

There remain two very important reasons which, if established, should suffice to justify the separation. The first is one to which I have frequently referred—viz., that in chlorosis the alteration in the blood is solely a diminution in its hæmoglobin, and in no other constituent. If this obtained of no other anæmia the distinction would be of value. But unless we enlarge the boundary of chlorosis until its territory becomes conterminous with that of idiopathic anæmia, this distinction will not hold. For it has not been proved, except in a few cases of pernicious anæmia, that the serum-albuminates are diminished in other forms of idiopathic anæmia besides chlorosis. There would seem to be no evidence of such diminution except when dropsical symptoms occur, and in those cases where there is general inanition. But in very many of the cases of idiopathic anæmia of the adult the body is well nourished and in this respect shows no difference from chlorosis. Lastly, there is Virchow's discovery of certain vascular anomalies in chlorosis, which of themselves, if of general occurrence, would suffice to create a distinction on the surest basis—viz., an anatomical one. I may be permitted to briefly describe these anomalies, which have also been met with by Rokitansky and Bamberger. There is considerable narrowing of the aorta, which can hardly admit the little finger, instead of the thumb, its normal size. It is quite infantile in size. Its walls are much thinner than normal, but their elasticity is very marked, even excessive. The intima is the seat of irregular thickenings in the form of wavy, or trellice-like, elevations, with ridges, between which are depressions. The inner coat is, moreover, often the seat of diffuse fatty degeneration, limited to the superficial layers, and forming yellow patches and striæ, especially between the intercostals in the posterior wall of the aorta. Sometimes this degenerative change extends to the muscular coat. Finally, there are anomalies in the origin of the branches of the aorta, particularly seen in the irregular disposition of the intercostals. With these vascular imperfections there is sometimes a small imperfectly developed heart, but more often a large one, dilated and hypertrophied. The reason for this diversity is explained by Virchow, who, believing that the whole condition is one of arrested development of the vascular system (associated sometimes with stunting of the body), and, one may add, of the blood, would recognise a small heart as part of this general change; but if the volume of the blood increases, this, together with the narrowness of the aorta, would be a sufficient cause for the enlargement. This vascular hypoplasia may or may not be associated with an ill-developed condition of the uterus and ovaries, which Rokitansky thought the rule in chlorotics. But neither of these congenital defects—or, more correctly, defects in the evolution of the vascular or of the generative apparatus—can be considered as underlying every case of chlorosis, or, at any rate, existing as a cause of the anæmia. Moreover, the vessels are liable to great variations in size, the intercostal arteries are very inconstant in their mode of origin, and narrowness of the aorta has been often described in cases where there were no symptoms of chlorosis during life. It is, however, a valuable and suggestive contribution to the subject, opening up the line of thought that in chlorosis we have a condition dependent on imperfect evolution of the blood and vascular system, but no proof has been given that the diminution in size of the vessels has not followed upon diminution in the total quantity of blood.

---

[1] Moriez: La Chlorose. Paris: Masson. 1880.

The history of chlorosis presents, in the majority of cases, a distinct etiological factor or factors, which cannot be ignored. Those who are most frequently its subjects are young women who have exchanged the light and air of the country for arduous domestic work in a town house, withdrawn from sunlight, undergoing considerable physical exertion in climbing stairs, or engaged in sedentary occupations in crowded and ill-ventilated rooms, or in many other ways subjected to conditions which we know to be prejudicial to healthy nutrition, whilst at the same time, by reason of their age and sex, they are more susceptible of such influences. There are changes then at work both around and within the organism all tending to the same end. It would be absurd to eliminate all the cases in which there are these etiological factors from the category of chlorosis because in other cases the disease develops without them, for it is impossible to say to what extent they act in inducing the anæmia. And the symptoms of chlorosis are those of anæmia. The increasing pallor, breathlessness on exertion, palpitation, headache, vertigo, and general nervous irritability, the fatigue induced by slight effort, the physical and mental enertia, the cardiac and vascular signs, the marked thirst, frequent derangements of digestion, and the character of the urine. These and other symptoms can be directly attributed to the anæmic state. Nor is the course of chlorosis quite apyrexial in all cases. It is often so, but it is not very unusual to find a temperature of about 99°, with slight exacerbations to 100° or 101°, a mimic reproduction of the irregular "anæmic fever" that appears in pernicious anæmia.

Finally, what are the characters of the blood in chlorosis as regards hæmoglobin and corpuscles? This has been thoroughly inquired into of late years, and in my first lecture I referred to some of the facts concerning this matter. I may briefly recapitulate and extend these points. There is invariably a reduction in the total quantity of hæmoglobin, a reduction reaching, according to the early researches of Duncan, about one-third of the normal. According to Quinquad the hæmoglobin is diminished about one-half in moderate chlorosis, varying between 70 and 30 grammes, instead of 125 grammes (which is the normal quantity), per 1000 grammes of blood, and the capacity for oxygen is very greatly reduced. The same observer declares, further, that the chief saline constituents of the corpuscles—the potash, salts, and chlorides—are appreciably diminished, but that there is no change in the amount of the stromal globulin. In a series of observations by Hayem, where the number of corpuscles was estimated in relation to their richness in hæmoglobin, this latter was found to be on an average about 50 per cent. of the normal, and in a few cases in which I have made similar calculations this diminution has been almost as marked. But there is not, as a rule, a corresponding diminution in the number of corpuscles. The mean of eighteen numerations by Hayem gives 3,520,000 corpuscles per c. mm. of blood, or 70·4 per cent. of the normal; and of seven cases I find a mean of about 3,000,000, or 60 per cent., there being, however, remarkable variations in the total number of corpuscles in different cases. For example, in one well-marked case where the percentage of hæmoglobin was only 45, the number of corpuscles was 4,050,000, whilst in another the number of corpuscles was only 2,090,000, with 32 per cent. of hæmoglobin. Such examples as these—and they might be multiplied—prove what I have before pointed out, that the number of corpuscles is only one factor in the degree of an anæmia, their value as to hæmoglobin being the more important factor. Especial attention has been paid in chlorosis, as in pernicious anæmia, to alterations in the form and size of the corpuscles. Malassez declares that the corpuscles are, as a rule, larger than those in health in the ratio of 1·09 : 1, and others have found a certain number of truly giant corpuscles, with a diameter of 12 μ instead of 7·7 μ (Hayem). More striking, however, is a departure from the normal in the contrary direction, these, according to Hayem, forming an undue proportion. He lays much stress upon the abundance of these small elements or "hæmatoblasts," which, it will be remembered, he considers as the early form of the adult corpuscle, and believes their accumulation to point to the incomplete development or evolution of the blood. The same observer has also noticed great variations in the form of the corpuscles, which bring to mind the variations described in pernicious anæmia by Quincke. I cannot say that I have been enabled to confirm this; certainly the corpuscles seem to be very variously sized, and to be more plastic and softer than in normal blood, forming rouleaux which are far more irregular, whilst the corpuscles, too, seem to be flattened out and otherwise slightly altered in form, but the extreme variations in size and in form, except after exposure (when they more rapidly become crenated than do healthy corpuscles), I have not seen.

The effects of treatment, especially of ferruginous medication, are so remarkable in those cases of idiopathic anæmia which are styled chlorosis as to be in sharp contrast with the other forms occurring in the adult. In a very short time under such medication the blood regains nearly its normal standard. Sometimes this improvement is permanent, but often the anæmia returns at some later date, under the influence of some exciting cause. There is an anæmic tendency in such individuals which might be explained by the anatomical defects described by Virchow, in which case the disease would be practically incurable, but which seems more probably dependent on a defective evolution of the blood-forming organs.

I have ventured to point out these matters because of the difficulty, which I feel sure is a real one, of deciding in any given case whether it is a chlorosis or not. It is not a mere question of nomenclature; if that were all it would matter no whit by what name we signified these conditions, but it is the difficulty which has arisen in consequence of the word "chlorosis" being held to convey more than the word anæmia, and being also arbitrarily considered inapplicable to idiopathic anæmia arising in later life. It may be most desirable, as Immermann[2] rejoices to think it is, that in chlorosis we have a distinct malady rescued from being merged in the "great ocean of anæmia," but unless its distinctive features can be more sharply defined than they are at present, the difficulty of separating it from other forms of idiopathic anæmia will constantly be felt.

---

[2] In his article on Chlorosis in Ziemssen's Cyclopædia.

I desire now to speak shortly of two of the more constant and striking effects produced by the anæmic condition—the signs furnished by the heart and bloodvessels, and the influence it has in determining fatty degeneration. Upon the former of these points, which has been the object of so much controversy and speculation, I hardly feel qualified to speak with authority, not having studied the matter so deeply as many. It seems to me, however, that as regards the production of so-called hæmic murmurs, we have to consider, not only the factor of the blood-impoverishment, and especially its diminution in quantity, but also the factor of the conditions of the walls of the heart and bloodvessels induced by that impoverished blood. Indeed, the idea that the murmurs are solely due to the first of these factors has, I believe, been almost abandoned; it did not afford an adequate explanation, and seemed to be contrary to physical laws. As regards the purely *cardiac* murmur, there are at least two conceivable explanations for it in which the condition of the muscular walls (dependent on the anæmia) is primarily involved. One of these is that the heart is dilated, and the murmurs are produced by its cavities being incompletely filled, and the other that there is actual regurgitation through the tricuspid and mitral orifices owing to the imperfect action of the enfeebled papillary muscles deranging the mechanism of the valves. Besides these cardiac bruits there are murmurs produced over the pulmonary artery and aorta. All of these murmurs are systolic in time, and vary much in intensity and situation; the most constant seat being at the base of the heart, the next at or within the left apex. Dr. Pearson Irvine, whose loss we have had so grievously to deplore, studied this subject for a long time, and embodied his conclusions in a paper read before the Royal Medical and Chirurgical Society in 1877. He started from the ground that dilatation, especially of the left ventricle, is the chief cardiac change in chlorosis—an opinion promulgated by Stark,—and endeavoured to explain the murmurs not obviously vascular on the fact of this dilatation. One may admit the fact that in many chlorotics there are signs of this dilatation. The matter, however, is very difficult of clinical proof, but it is supported by the post-mortem evidence of hypertrophy by Virchow and Lewinski—a hypertrophy which is as conceivably produced secondarily to a dilatation, as to a narrowed aorta. The known relation between anæmia and fatty degeneration of the heart supplies us with ground for believing that in slighter cases the heart muscle is enfeebled; and probably also its innervation is affected by the impoverished blood. Dr. Irvine differentiated four cardiac murmurs in chlorosis, having their points of maximum intensity over the left auricle and its appendix, at the left apex, over the fourth left costal cartilage, limited there or transmitted downwards to the right or left, and lastly, in the fifth left space, below it or over the sternum adjacent to it. He was inclined to attribute the production of these murmurs to the dilatation of one or both ventricles, and did not favour the view that any of them were due to regurgitation. The regurgitant hypothesis, which explains the auricular murmur as well as those met with about the region of the apex, is supported on the left side by the almost constant accentuation of the second pulmonary sound, and on the right side by the occurrence of jugular pulsation. The mechanism of this regurgitation may be either a slight inadequacy in the contraction of the papillary muscles, or it may be dependent on dilatation. Although the basic systolic murmur may be in many instances due to this regurgitant eddy into the auricular appendix, there can be no question that bruits are heard strictly over the aortic and pulmonary areas. Of the mode of the production of the former (which are not common) no adequate explanation has been given; but of the latter, the true pulmonary bruit, we have Quincke's view that in the cases where it is marked, the lung is retracted and the pulmonary artery slightly compressed at every systole; and we know how pressure by the stethoscope will increase the intensity of these bruits.

The murmur heard in the carotids and other arteries is only an exaggerated degree of what can be heard in health, and is probably due to the impaired tonus of the vessel allowing it to be more readily influenced by slight pressure.

The hum in the jugular vein—to which more significance has been attached than it merits, as shown by Dr. Herbert Davies—is produced by pressure, and increased in intensity whenever the flow of blood is accelerated. This is illustrated in the influence of posture—its increase in the standing position in the rise and fall of the otherwise continuous blowing sound, with the respiratory movement, the increased aspiration into the chest with every deep inspiration being accompanied by increase in the intensity of the murmur, which can be entirely arrested by forced expiration. It is noticed also that the auricular and ventricular diastole influence slightly the intensity of this bruit, so that in it we have a measure of the variations in celerity of the venous blood-flow.

I ought not to leave this part of the subject without alluding to the hypothesis advanced by Dr. Goodhart,[3] that anæmia may be at the foundation of some of those valvular diseases, especially of the mitral valve, the etiology of which is still obscure. He thinks the evidence conclusive that in anæmia there is ventricular dilatation, just as there is post-mortem evidence of muscular degeneration, and suggests that the continuance of this regurgitation may submit the valves to so constant and irregular a strain as to lead to alterations in their intimate structure, thickenings and puckerings, productive of permanent regurgitation and possibly some stenosis.

ON THE

NATURE AND SEQUENCE OF THE CARDIAC AND VASCULAR CHANGES IN INTERSTITIAL NEPHRITIS.

BY B. C. WALLER, M.D., F.R.C.S. EDIN.,
LECTURER ON PATHOLOGY IN THE EDINBURGH SCHOOL OF MEDICINE.

THE short yet very able rejoinder (THE LANCET, March 12th) made by Dr. George Johnson to my papers in THE LANCET for the 5th and 12th of February appears to call for some brief additional comment. When my articles were written I had not seen Dr. Johnson's paper in the *British Medical Journal* for May 25th, 1878, and was consequently unaware that he had ceased to maintain the muscular character of the inner longitudinal layer of the thickened coats of the arterioles in interstitial nephritis. In the two papers just mentioned, Dr. Johnson expresses his conviction that the layer of longitudinal thickening is due to a physiological increase in the elastic or outermost portion of the tunica intima. He bases this conviction upon the following reasons:—Firstly, this thickened inner layer has precisely the same structural appearance and arrangement as the elastic layer in the larger, but still microscopic arteries, the increase being probably ascribable to the necessity on the part of the arterioles for resisting that tendency to elongation to which they are subjected under the strain of the increased injecting force of the hypertrophied left ventricle. Secondly, the thickening being constant and uniform in its structural characters, and presenting essential points of difference from syphilitic or tuberculous thickenings, it is probable that the true explanation of its nature is to be sought rather in the direction of physiological hypertrophy than in that of pathological change.

My reply to these arguments rests principally on the ground that this uniformity in the structural character of the thickened intima is not observable in my specimens. On the contrary, the shape and arrangement of the elements of the intima in different examples are subject to very considerable diversity. For descriptive purposes I may distinguish two principal varieties of thickening—namely, the fibrous and the cellular. The fibrous variety is evidently that to which Dr. Johnson alludes. The arteriole figured by him in the thirty-third volume of the Medico-Chirurgical Transactions, page 114, is an excellent example of it. A somewhat minor degree of the same kind of thickening is represented in Plate 4 of my monograph on Interstitial Nephritis. Were this the only kind of thickening I should feel less hesitation in regarding it in the same light with Dr. Johnson, even despite certain difficulties which might be suggested by a consideration of the permanent and stable nature of elastic tissue. But the characters of the cellular varieties of thickening appear to me to negative this hypothesis, and to force upon us not only the idea of pathological change, but also that of inflammatory connective-tissue multiplication. Take, for instance, the arteriole, a portion of whose wall I have figured in Plate 5 of my monograph. Here the thickened tunica intima, far from being exclusively fibrous, contains a large number of rounded or ovoid cellular elements, which can hardly be regarded as anything else than the products of a pathological multiplication of the connective-tissue cells of the middle layer of the inner coat. The elastic elements of the outer layer of this coat are visible as a number of sharp wavy lines separated from one another by the elements originating in the proliferative process. When viewed in transverse section under a power of about 600 diameters, these lines are seen to run through the thickened intima, presenting an appearance somewhat comparable to that of river-markings on a map. It is difficult, indeed, to resist the conviction that the wavy lines represent the split-up and displaced lamellæ of the elastic or outer layer of the inner coat, while the bulk of the thickening is constituted by an increase in the number of the elements forming the connective tissue or middle layer. The structural peculiarities of this variety of thickening are almost identical with those visible in many syphilitic arteries. The patient whose kidney contained the arteriole figured in Plate 5 was, however, known not to have suffered from syphilis.

---

[3] THE LANCET, vol. i. 1880, p. 479

I purposely omit all mention of the appearances observed in the vessels of the remarkable kidney, an arteriole from which is represented in Plate 6 of my monograph. In this case the arteries were waxy, and there was a suspicion of syphilitic history which might tend to invalidate any conclusions based exclusively upon a consideration of the changes in the vessels of this specimen. Accordingly, lawyer-like, I prefer not to cross-examine a doubtful witness. I have, however, in my possession, a number of specimens in which the arteries are in a very similar condition. In these there is no warrant whatever for the supposition of a causatory syphilis.

It now remains to explain the reasons for my hesitancy in accepting Dr. Johnson's etiological explanation of the arterial and cardiac hypertrophy of interstitial nephritis as being due to an antagonistic action on the part of the heart and arteries, the one insisting on supplying the poisoned blood to the various tissues, and the other, in obedience to vaso-motor mandates, doing their utmost to exclude it.

My first objection is an *à priori* one, and shares of course to some extent in the weakness of all such arguments. It is this. The tendency of the various factors in all living organisms inclines so obviously towards mutual accommodation, that one is conscious of a *primâ facie* reluctance to admit the existence of long continued antagonism on any grounds short of absolute demonstration. But Dr. Johnson replies, In what other manner can we account for the high arterial tension and increased cardiac action in certain cases of acute renal disease with uræmia? In the first place, I might rejoin that in these cases the time necessary for the establishment of a give-and-take toleration is not allowed. A transitory antagonism is more conceivable than a persistent refusal to come to terms. But the real objection to this ingenious argument from analogy appears to me to be the following. Increased cardiac action with high-tension pulse are by no means invariably observable in cases of uræmic toxæmia. In all such cases the blood is presumably poisoned; why then are the consequences as regards the heart and vessels not invariable also, or at least fairly constant? Yet the name is legion of those cases of uræmia where the heart's action is insufficient, and the pulse slow, compressible, irregular, and intermittent — and this not merely in the later stages, but even from the very outset. What then is the explanation of this non-uniformity? Is it not to be sought in the constantly threatening tendency to serous and other inflammations, which constitutes so ever imminent a contingency in these cases? Congestion of the lungs, pneumonia, pleurisy, pericarditis, and peritonitis are each and all of them sufficient to account for a high-tension pulse and cardiac overaction. So too is that inflammation of the alimentary canal which occasions the severe diarrhœa so frequently seen as a harbinger or concomitant of uræmia. We cannot but recognise the influence which incipient inflammatory conditions of this kind must exercise on the circulation. According to my observations of uræmic cases, circulatory inefficiency is quite as frequent as excitement; and I have been accustomed to regard the latter, not as a consequence of antagonism between heart and arteries, but as a warning to be on the alert for inflammatory complications.

I have been led to the opinion that the hypertrophy of the heart in interstitial nephritis is due to diminution in the calibre of the arterioles, because of the apparent relation subsisting between them in those cases which I have hitherto examined. I do not consider my series sufficiently extensive to warrant as yet the expression of a positive opinion; and I therefore merely wish to indicate, in the meantime, the direction in which the balance of evidence appears to incline. There can, however, be little doubt that a condition of thickening of the tunica intima is very common in cases of interstitial nephritis; that it reduces the calibre of the arterioles generally; that this diminution in the sectional area of the arterial conduit-pipes must tend to produce a rise in the blood pressure; and that this rise in the blood pressure must be compensated by cardiac hypertrophy, either as direct result or concomitant, if the efficiency of the circulation is to be maintained. These considerations, when viewed in relation to the fact that in eighteen cases a very constant relation was maintained between the diminution in the calibre of the arteries and the degree of cardiac hypertrophy, seem to point in the direction of a strong probability, which further observations must either negative or confirm.

I have already indicated my present inability to propound a feasible explanation of the causes which issue in the production of hypertrophy in the tunica media of the arterioles. I trust that a new series of observations, which I am preparing to undertake, may possibly throw some light on the subject. If anyone has explained the *raison d'être* of this unquestionable feature in the morbid process, it is Dr. Johnson; but in the absence of further evidence, I cannot but regard his ingenious theory as provisional and tentative. A few carefully conducted experiments on animals by the administration, say of ergot, for a prolonged period, might do much towards settling the question as to whether continuous contraction of the muscular coat of the arterioles might or might not, in the absence of obliterative changes in the intima, prove sufficient to give rise to hypertrophy of the muscular fibres of the heart, and those of the arteries themselves. At present, however, when the head of every tomcat in the British Islands is held as sacred as that of the bull Apis in ancient Egypt, it is to be feared that any and every theory pertaining to this subject must remain unsettled in the absence of experimental corroboration.

Edinburgh.

ABSCESSES CONNECTED WITH BARE BONE, TREATED WITH AND WITHOUT LISTER'S METHOD.

BY HENRY MORRIS, F.R.C.S.,
SURGEON TO THE MIDDLESEX HOSPITAL.

THE object of this communication is to ask a question and to state a case. In a recent number of THE LANCET there was an account by two able and well-known men of a phthisical young man, aged twenty-six, who had an abscess situated over the fifth rib, which was opened "antiseptically" on December 7th, 1879. A few drachms of thick curdy pus were evacuated, and the surface of the rib was found to be bare and rough for nearly two inches. On February 23rd (i.e., eleven weeks after the abscess was opened) the drainage-tube was extruded and the wound healed. The commentary is: "This affords a beautiful illustration of the power of nature to repair, if only protection be afforded, against fresh irritation. The diseased bone was kept free from all irritation, escape being provided for the discharges preceding and accompanying repair, and perfect asepticity being secured by the use of Lister's method. Had the abscess been opened without antiseptic precautions, prolonged fetid suppuration and exfoliation must have resulted."

The questions I would ask are: "Can the infatuation of disciples—*addicti jurare in verbis magistri*—go beyond this?" "Does not any system which has good in it flourish rather than suffer by such tributes to its glory as the above?" "Is it in accordance with the principles which should render to carbolic acid the praises which belong to it, and to common sense and the ordinary process of repair the tributes which belong to them?" The following case may assist to an answer :—

On Nov. 11th, 1880, Ellen W——, aged twenty-six, a weakly, very anæmic and pale-looking blonde, who all her life has had bad health, was admitted into Regent ward of the Middlesex Hospital with an ovoid swelling the size of a large walnut in the roof of the mouth, projecting downwards towards the tongue. It was situated chiefly on the right of the median line, and fluctuated and discharged daily a small quantity of rather offensive matter into the nose as well as into the mouth. Her jaws were filled with the decayed, ragged, and offensive stumps of molar and bicuspid teeth. The swelling in the mouth appeared three weeks before admission, and was attributed to the irritation caused by the first right upper bicuspid tooth, which had been for a long time carious, and had decayed away, leaving only a stump. This stump was extracted nine days before admission. A fortnight before coming in the swelling on the palate was lanced by the patient's regular medical attendant, and a quantity of blood and matter came away. It filled again in three or four days, and subsequently broke of itself, and discharged in two places—one where lanced, and one just behind the front teeth. A week before admission the discharge into the nose began. The mouth was slightly examined on the day of admission, but owing to her weak state of health and her fainting under examination, nothing was done until the next day (Nov. 12th), when a free antero-posterior incision was made into the abscess, and two or three drachms of mixed blood and pus evacuated. With a probe the whole palate process of the right maxilla was felt bare and rough, and the probe passed through a carious opening from the mouth into the right nostril. A wash for the mouth, consisting of Condy's fluid, was ordered, and the wound was kept open by the daily introduction of a probe. On Nov. 25th there was still some fulness in the seat of the abscess, but the mucous membrane had settled down upon the hard palate again. The mouth was still in a bad state owing to the stumps of teeth.

Dec. 3rd.—Palate looks quite sound, but patient thinks there is a trace of discharge at night into the mouth. She describes an uncomfortable "hollow sort of feeling" in the nose when she goes into the cold air. Is now well enough to bear the extraction of the stumps, all of which are to come out. The right second incisor, which was decayed, and two stumps were removed this morning.—Dec. 11th: There is now nothing wrong to be detected about the palate. Five more stumps have been removed since the 3rd of Dec. She is very much improved in health, and now only remains in hospital to have the other stumps removed.—Dec. 21st: Discharged well.

Remarks.—Cases are numerous enough in which an abscess connected with rough bare bone has been opened without what is now understood by the antiseptic precautions and dressings, and where no exfoliation has followed. But the above case is one in which such an abscess was opened not only without the perfect asepticity secured by the use of Lister's method, but in the presence of unavoidable and most septic conditions, the pent-up matter of the abscess having a communication with the nose, as well as with the mouth and its offensive tooth stumps. Yet neither exfoliation nor prolonged suppuration resulted, and the abscess, thanks to the ordinary processes of repair, was quite well in less than four weeks.

This case is open, no doubt, to the argument that the presence of the decayed and foul stumps was an important and most favourable element in the recovery, serving as potent centres to attract the germs of putrefaction, and thus draw them away from the abscess cavity and the diseased palate bone, like wasps which hover about the cracked and over-ripened fruit of the greengage tree to the neglect of the heliotrope and roses. Further, this deduction—it would not be a logical one—may be made from the case—namely, that it would be well in every instance to have a powerful centre of putrefaction at no great distance from a wound in order to serve as a counter-attraction for the said germs. I am not, however, disposed to agree with so cynical a disputant; any more than I can believe, even when asked to do so by distinguished men, especially with the evidence of such cases as the above before me, that Lister's method is requisite for the cure of these abscesses.

It has for some time past been quite the general practice in describing any successful operation, be it never so simple, or one ever so frequently performed, to state that it was done under Lister's method, and to imply that the success was chiefly due to the employment of this method. If this habit continues the students of medicine in the immediate future will run the risk of growing up to think that before the use of the "antiseptic system" there could have been no successful surgery at all; and when they get into country practice they will have to make provision for always carrying on horseback, or in their gig, a steam spray and rolls of gauze and protective, so as to avoid the qualms of conscience which must follow if in a weak moment they open an abscess without these precautions, and make the horrible discovery that there is rough bare bone. Every week contributes its quota to this end, and we are almost persuaded to think that without carbolic acid there can be no good from herniotomy, no safe colotomy, no satisfactory excision of a tumour or a joint. Such are the expressions which are daily heard that one cannot help feeling, with one of my old teachers at Guy's, a past President of the College of Surgeons, who said, "If all we now hear is true, I wonder we old fellows ever had a successful operation." It is to be hoped, for the sake of the just appreciation of Lister's system, that many of these "old fellows" will long remain amongst us, to hold the balance between the true and false, and to recall to our minds some of the successful results of pre-Listerian practice.

Mansfield-street, W.

ON THE HERPES IRIS OF BATEMAN.

By T. COLCOTT FOX, B.A. CANTAB., M.B. LOND.,

PHYSICIAN TO ST. GEORGE'S AND ST. JAMES'S DISPENSARY, ASSISTANT-PHYSICIAN TO VICTORIA HOSPITAL FOR CHILDREN, AND PHYSICIAN TO SKIN DEPARTMENT OF NORTH-WEST LONDON FREE DISPENSARY FOR SICK CHILDREN.

OUR largely-growing knowledge of diseases of the skin, which has resulted from the general advancement of medicine and surgery and the special increase of work in a long and much-neglected section, has borne fruit in the fulfilled desire for a more scientific classification and a simplification of the grouping of these diseases. In the latter process, however, there may arise a danger of being hurried on too fast, and it is well to call a halt occasionally, and make sure of our ground, that we may not introduce confusion by having subsequently to retrace our steps. It is my intention by the following remarks to ask careful consideration of the subject before we yield to the growing tendency amongst dermatologists to swamp, as it were, in the group erythema multiforme the rare but very characteristic disease herpes iris, so well described by Bateman. Unquestionably a very real advance was made by Hebra when he grouped together under the term erythema multiforme the various varieties of inflammation of the skin, hitherto described as erythema annularis, iris, papulatum, tuberculosum, circinatum, and so on, because, although each of these varieties has distinctive features both as regards site, appearance, &c., they are frequently associated together, and are undoubtedly mere varieties due to the amount and site of the fluid effusion, and to the mode of extension of the inflammatory process. Now, it is an all-important point to recognise that the effusion of fluid in sufficient quantity or superficially enough to form vesicles or bullæ is a perfectly natural stage of the erythematous inflammation, although an exceptional termination, and by no means to be regarded as a characteristic feature. Still the term erythema ("inflammatory blush") must for the future be given a wider significance than heretofore, and must denote a type of inflammation which may exceptionally, but naturally, terminate in vesiculation. When the process is very acute or the effusion of fluid superficial enough we see such vesiculation exceptionally in many varieties of erythematous inflammation, as—e.g., in urticaria (U. bullosa, which has been described as pemphigus), in the cruptions produced by the ingestion of some balsams, in the erythematous rashes characterising many of the acute specific fevers, in erysipelas, &c. And, further, it is necessary to note that from the peculiar evolution and spread of the inflammatory process the vesicles or bullæ may be arranged singly or grouped in some variation of the annular pattern.[1]

In herpes and pemphigus, on the other hand, the effusion of fluid sufficient to form vesicles or bullæ is a characteristic and almost constant feature, though exceptionally the eruption may abort or stop short of this. In pemphigus it is usual, and in the "vesicating erythemata" very exceptional, for the vesicle or bulla to rise directly without the intervention of a marked erythematous stage. In herpes the many vesicles are aggregated characteristically on an erythematous base; in pemphigus the vesicles or bullæ (for the collections of fluid may be very tiny) are usually disseminated singly, but they may be in groups of a serpiginous or other pattern.

---

[1] Those interested specially are referred to a posthumous paper by the late Dr. Tilbury Fox, which I edited for the January number of the Archives of Dermatology, 1880, entitled A Clinical Study of Hydroa.

Bearing these facts in mind, it appears to me that between the essentially vesicular or bullous diseases known as herpes and pemphigus and erythema multiforme, which is only exceptionally vesicular or bullous, it is desirable still to retain a place for Bateman's characteristic affection herpes iris. And chiefly for two reasons: firstly, because in my experience, and I have notes of many cases, it is an essentially vesicular disease; and, secondly, because it is almost always associated with the vesicular eruption known as herpes facialis or preputialis, certainly a very rare complication of even "vesicating erythema." I would not lay much stress on its symmetry, its colouring, its very constant site on the hands, knees, and insteps, nor on its strongly recurrent tendency and the influence of the seasons in its production, because though of great value collectively these features unquestionably tend to separate it from true herpes and bring it very close indeed to erythema. The peculiar form of the eruption, dependent on the presence of a central umbo and one or more successively surrounding rings of distinct or confluent vesicles, points to a mode of evolution characteristic also of the erythemata, but here I would clearly state my view that I do not include under herpes iris those rare cases of vesicating erythema in young children, of which I possess drawings, and which were recently described at the Clinical Society, though some of these lesions are identical in appearance. I am not concerned to retain the term "herpes iris," because the term herpes nowadays has a precise meaning, and I cannot agree that the disease under consideration falls within that definition. In conclusion, therefore, I would plead for the retention of Bateman's herpes iris between true herpes and the erythemata, but as far more closely allied to the vesicating forms of the latter than to the former.

Harley-street, W.

ON THE TREATMENT OF CLOSURE OF THE JAWS.

By W. DUNNETT SPANTON, M.R.C.S. Eng.,
SURGEON TO THE NORTH STAFFORDSHIRE INFIRMARY.

I can discover in works on surgery very little information on the subject of closed jaws, and still less that is satisfactory in the matter of treatment. We find the affection usually dismissed in about half a dozen lines; and yet to a limited extent the matter is of some importance, and I propose to direct attention to one method of relieving the affection which, so far as I know, has not been usually practised.

Various causes have been assigned for what Gross calls "this distressing affection," the principal being cicatrices of dense unyielding tissue caused by some form of ulceration, such as ptyalism; anchylosis more or less complete, from injury, or inflammation of temporo-maxillary joints; contraction of the structures surrounding the joint, particularly the masseter and pterygoid muscles; a bony connexion between the upper and lower jaw; and from pressure caused by a neighbouring tumour or enlarged glands. I do not now refer to spasmodic closure, which would seem to depend on reflex irritation, such as the eruption of wisdom-teeth, tetanic spasm, &c.

In the two cases which I will very briefly notice, there appeared to be no other cause for the immovable condition other than anchylosed temporo-maxillary joints; and, as I shall presently show, this depended on a condition which would seem to be quite analogous to that of other joints, such as the knee, occurring as a sequela of certain diseases—such, e.g., as scarlet fever and measles. We have, in fact, to deal with a joint in which there has been inflammatory mischief at some previous time, with resulting contraction of the surrounding ligaments and tendinous structures. This consideration led me to adopt the mode of treatment which is found so serviceable in dealing with a like condition in cases of stiff knee or genu valgum—that is, to divide the ligaments in such a way as to release the joint. Various objections to such a procedure will no doubt readily suggest themselves, as they did to myself; but I think that in the two following cases the result justified the means.

The first is that of a girl, aged ten years, Ada M. R——, who was admitted under my care in the North Staffordshire Infirmary in April last year. About six years before she had scarlet fever, which resulted in hip-joint disease, and in a subsequent closure of the mouth, which had never been relieved. On admission she was very thin and ill-nourished, owing to her inability to masticate food. The mouth was firmly closed, and under chloroform it was found impossible to open it, although one tooth was broken in the attempt. There were no marks of cicatrices either in the mouth or externally; the digestive muscles were fully developed, and there was no unusual rigidity of the masseter or temporal muscles, nor was there any glandular swelling or other apparent cause for the condition of the mouth. The right hip was dislocated from disease of the joint, coincident apparently with the temporo-maxillary affection, but in a perfectly quiet state. She was able to take only liquid food, or such as she could squeeze with her fingers between the teeth.

Believing that the immobility was dependent on an anchylosed state of the temporo-maxillary joints, with probable contraction of the ligaments surrounding them, and failing to make the slightest impression by means of a gag with any justifiable amount of force, I passed a very narrow tenotomy knife into the temporo-maxillary joint on each side, immediately in front of the temporal artery, and then passed it freely round the condyle of the inferior maxilla as far as I deemed prudent, dividing completely the external lateral ligament of the joint, and partially the insertion of the external pterygoid muscle, keeping the back of the knife towards the temporal, and carefully measuring the depth of incision so as to avoid the middle meningeal artery. It is not a particularly happy spot to tenotomise in, but very little hæmorrhage occurred; and as soon as this procedure was effected I found that the joints at once yielded to the gag, and the mouth could be opened to the extent of more than an inch. For a day or two some soreness was complained of, but the gag was used almost daily, and seven weeks afterwards the patient left the infirmary able to open the mouth fairly well and to masticate her food. As a result of this her general health greatly improved. She continued well, and was able to go to school, but the use of the gag from time to time was neglected, and by degrees the stiffness began to return. At the end of November she came under my care again, very much improved in health, but with the mouth closed so far as only to admit the tip of one's finger. I accordingly repeated the operation, taking care to divide the structures, especially anteriorly, more freely than I had on the former occasion; and the result has been much more marked than it was before. She can now open the mouth to some extent without assistance, and with the use of force it can be opened wide without causing pain. There is, however, very slight lateral movement.

The second case is that of a girl aged nine, Sarah Ann B——, who was brought to me in November, 1879, for a closed mouth. She was a delicate-looking child, had been deaf from early childhood, and about two years and a half before I saw her had scarlet fever, after which the gradual closure of the jaws took place. This was naturally accompanied by a corresponding decline in her health and strength, for which her friends sought relief. The mouth was quite firmly closed, and with no legitimate amount of force could it be moved. Under chloroform I operated as in the former case, and by means of a screw gag opened the mouth freely. No untoward symptoms beyond some swelling and tenderness about the temporo-maxillary joints occurred, and by the frequent use of the gag by the patient's friends at home, she can now open her mouth sufficiently to take any kind of food, and I am glad to say is now recovering very fair lateral movement also. She can open it to the extent of more than half an inch without assistance, and is able to masticate her food thoroughly. This has led, as we hoped it would, to a corresponding improvement in her general health.

In these cases, when I found it impossible to force open the jaws, I was inclined at first to practise Esmarch's method of excising the joint, or Rizzoli's plan of dividing the ramus of the maxilla; but as I happened to see the first case in which the former operation was performed in this country by Mr Mitchell Henry many years ago, and which resulted in a rapidly fatal issue, I was led to try the milder measures I hav described; and as an alternative of the more severe operations for the relief of this troublesome affection the plan is one which is, I think, deserving of a more extended trial. I would only further suggest that it should be practised cautiously.

Hanley, Staffordshire.

CASES OF SUDDEN OBSTRUCTION OF THE ŒSOPHAGUS.

By PUGIN THORNTON,
SURGEON TO THE ST. MARYLEBONE GENERAL DISPENSARY.

LAST year two cases of stricture of the œsophagus came under my notice, in both of which a sudden obstruction to the passage of food was the first symptom of disease. In the first case the affection proved to be of a benign nature, in the second malignant. I venture to bring these cases forward because sudden and extreme dysphagia, attacking a person apparently in good health, is a rare condition, and one which must affect a surgeon's ability to determine upon the nature of an œsophageal stricture. Sir James Paget, who saw the second case, tells me that he has never before known sudden obstruction to the passage of food to be the first symptom in cancerous stricture of the gullet. The first case is also of much interest, because in most respects it resembled one of malignant disease.

CASE 1.—Mrs. ——, over sixty years of age, was sent to to me by Mr. W. H. Evans, of the Finchley-road. Mrs. —— informed me that four days previously, during dinner, a piece of meat had stuck in her throat, and that it was with great difficulty she had managed to pass it down, that for some hours after the accident she had been unable to swallow anything, and then, and till the time she saw me, she had only been able to take liquids drop by drop. The patient was in good health at the time of the accident and had never before found difficulty in taking food. She had been apt, she acknowledged, to hurry through her meals, although unable to masticate her food properly, her teeth not being in good order. Since the accident Mrs. —— had felt continuous pain in the right ear, and had been troubled with a constant collection of frothy phlegm. In swallowing she also felt pain between the cricoid and sternal cartilages. Her expression was anxious. She was very thin, but was not aware that she was thinner than she had been for years. The larynx and surrounding parts were normal in appearance. Mr. Evans had written to say that he had been unable to pass an instrument through the stricture, and I also met with the same difficulty, the constriction being opposite the cricoid cartilage. At first beginning with a large-sized bougie, I made steady and protracted pressure on the stricture, and I then tried quickly through some of the smaller instruments. On March 13th I could pass a bougie down the left side of the gullet, but on the right side the œsophageal canal was still firmly closed. Mrs. —— had been able to take small pieces of dry bread, and could now drink without stopping. The pain in the right ear continued, but was not so severe, and the anxious expression in her face had disappeared. This patient made a complete recovery, and has remained free up to the present time from any relapse, although she has since, I have heard, been through a severe attack of pneumonia.

CASE 2.—Major ——, aged sixty-two, consulted me on March 23rd, 1880, on account of dysphagia which had troubled him for three weeks. When he came to see me he was unable to take solid food, and liquids only with difficulty. He said that the stoppage had come on suddenly during a meal, when he was apparently quite well. Finding himself unable to take anything he became very nervous, and for some hours would not make any further attempt to swallow, and when he tried he could only manage a teaspoonful of fluid at the time. On examination I found a stricture at the upper part of the lower third of the œsophagus, through which I could not pass the smallest-sized bougie. The patient was well nourished in body, nor had he noticed that he had lost flesh. His face was anxious, but presented no appearance of a cancerous cachexia. There was a murmur to be heard in the cardiac region, which, on consultation with Dr. Ringer, this physician pronounced to be aortic, and not aneurismal. For diagnostic purposes I asked this gentleman to pay me a second visit in a fortnight's time. I afterwards learnt that he was taken to Sir James Paget. He died a few weeks later.

At the post-mortem examination Dr. Hodson, of Bishop's Stortford, has informed me that he found a cancerous stricture, annular, but not complete, about one inch and a half above the cardiac orifice.

What the condition of the œsophagus was in the first case it is hard to say. It could scarcely be that the cricoid cartilage was diseased, or the patient would have felt pain on external pressure, and most probably some mischief would have been detected in the laryngeal examination. If we say that it was a case of spasmodic stricture it is difficult to account for the fact that on passing a bougie at the patient's second visit an obstruction was met with on the right side of the gullet, and not on the left. One would think that the closure of the œsophageal walls in the case of a spasmodic stricture would either give way all at once or equally from the centre of the canal, unless, indeed, in this instance a very slight and old-standing constriction of the mucous wall on the right side of the œsophagus was present at the time of the accident. Undoubtedly the circumstance of finding a complete stricture, apparently organic, in an old woman, attended with the symptom of constant pain in the right ear (the side, let it be noted, the stricture lasted the longest), and with the presence of a quantity of frothy phlegm, pointed in a great measure to the affection being of a cancerous nature.

Mr. Power, in 1866, related in THE LANCET (vol. i., p. 252) a case of stricture in which the patient died of inanition, but that on a post-mortem examination he found a perfectly natural condition of the œsophageal walls. In this case the difficulty of swallowing came on gradually, and a large-sized bougie was on one occasion passed by force through the stricture. By both patients I was asked to give a decided diagnosis. In both instances I was unable to do this. With regard to the case of Mrs ——, I explained that the nature of the illness could not at once be determined upon, but could only be cleared up by time; that although the condition of the patient was undoubtedly very serious, yet, at the same time, from the abnormality of the symptoms, there was reason for saying that the case should not be considered as hopeless. In the second instance, although one had the experience of the case of Mrs. ——, there was more reason to suspect that the stricture was of a cancerous nature on account of its position, but here again it was difficult to account for the suddenness of the attack, coupled with the absence of other signs, and the previous good health of the patient. Perhaps the proper course for clearing up the diagnosis in each case would have been to attempt to pass a bougie whilst the patient was under chloroform.

Devonshire-street, Portland-place.

PHANTOM TUMOUR.

By P. D. MALLIK, M.B.

ON Dec. 3rd, 1880, I was called to see a case of spurious pregnancy. The patient's history was as follows:—

M——, aged seventeen, married. No children, no miscarriages. Menses arrested since July, 1879. General health good. No family history of hysteria. A month after the cessation of her menses she had nausea and the usual sympathetic disturbances of pregnancy. About the second month the breasts became increased in size and tender, and afterwards became much larger and firmer; blue veins were seen crossing them. The nipples became turgid, and the changes in the areolæ were marked, and exactly resembled those seen in a case of true pregnancy. About the fifth month the abdomen was found to be prominent and enlarged. Quickening was perceived by the patient, and, what is more strange, apparent fœtal motions were observed. The patient was pronounced pregnant, and although she was suffering at the time from irregular attacks of intermittent fever, yet, according to the prejudices still unfortunately prevalent among a large section of the native community, she was not placed under medical treatment — the very fact of pregnancy being, in their opinion, a sufficient reason against the administration of any medicine. The size of the abdomen increased progressively until it resembled the gravid uterus at full term. Exactly at the end of nine months all the phenomena of labour supervened. Regular pains came on and continued to increase in force and frequency, but no progress was observed. The pains lasted about twenty-four hours, after which period the patient had an attack of intermittent fever. Days and months elapsed, but the labour pains never returned. The parents of the girl became anxious, and thought she had an abdominal tumour. Accordingly they sought medical assistance, and Babu Hara Lal Dutt, of Chandernagore, who was sent for, requested me to see the case in consultation with him. On inspection, the tumour was situated exactly in the centre of the abdomen, and extended from the pubes below to the ensiform cartilage above. The umbilicus was not protruded. There were no striæ over the abdomen. On palpation the tumour was found to be elastic; it had not the hard feel of a solid tumour. Its boundaries were not distinctly circumscribed. Firm, even, continued pressure perceptibly diminished the size of the tumour. The tumour had no connexion with the liver, spleen, ovaries, or uterus. On auscultation, neither the fœtal heart sound nor the uterine souffle could be heard. Rumbling noises were audible all over the tumour. On inquiring whether the patient ever had "fits," a negative answer was received, but we were told that she now and then complained of "globus hystericus." Taking all these facts into consideration, we diagnosed phantom tumour. To confirm our diagnosis, we placed the girl under chloroform. When complete anæsthesia was produced, the tumour entirely vanished from sight; but on withholding the administration of chloroform for a few minutes, it reappeared and assumed its former size and shape. Thus the fact of spurious pregnancy was established beyond doubt. We ordered ten-grain doses of bromide of potassium three times a day. Whether this medicine will do her any good time will show.

GUY'S HOSPITAL.

COMPOUND FRACTURE OF LOWER END OF FEMUR; ACUTE GANGRENE; FATTY EMBOLISM; DEATH.

(Under the care of Mr. BRYANT.)

FOR the following notes we are indebted to Mr. Dalton.

Chas. B——, aged thirty-two, was admitted into Accident ward on July 18th. At 11 P.M. on the 17th, while alighting from a waggonette at New-cross, he slipped, and the wheel after pushing him a little way, passed over his left thigh. He was taken to Guy's at 1 A.M. in a condition of marked collapse. He had fracture of the lower end of the femur. The arteries were pulsating. Ice was applied. In the afternoon of the same day the thigh swelled and became cold. The temperature rose to 102°. Mr. Lucas was called as gangrene had set in, but did not consider it expedient to amputate. By 11 P.M. the pulse was imperceptible, the face became cold, the leg swelled and became emphysematous. Incisions were made, but the gangrene extended to the abdomen, and the patient died at 7.20 A.M. on July 19th, thirty-two hours after the accident.

Post-mortem Report by Dr. FAGGE.—Face bloated and emphysematous, so also all parts of the body. The whole of the injured extremity was exceedingly tense from the distension of the tissues with gas. The scrotum also was blown up to a large size, and large bullæ of dirty fluid were spread about the buttocks and hams. Both lungs stained from blood soaking, though they were quite *warm*. On section of the lungs the exuding fluids were thickly covered with small droplets of oil of various sizes. I have frequently seen such a state in fat bodies previously; but as it was suspected the case might be one of fat embolism, I examined the parts very carefully, and I soon noticed that the oil had a peculiar glutinous appearance, and that it came in large quantities from the moderate-sized branches of the pulmonary artery. I could take them from the vessels on to my knife and show them to the class in quantity. The lung was otherwise perfectly healthy. — Heart: Healthy. A moderate amount of clot in each side. Muscle distended with gas from decomposition.—Liver: Healthy; distended with gas.—Spleen weighed six ounces and a half.—Lower limbs: Healthy. Knee-joint free from blood, and not implicated in any way by the fracture, which was a comminuted one in the lower third, running from in front and above downwards and backwards. It appeared to be an ordinary form of fracture. The vessels were in no way lacerated or even bruised, so far as we could see. The vein was examined in its whole length down to beyond the fracture, and the artery also. They were free from clot, though both were much stained with blood. This early decomposition is worth noting, as the blood was still quite warm when the inspection was made (eight hours after death). The man was a big muscular fellow, with a fair amount of fat on him.

COMPOUND COMMINUTED FRACTURE OF LEG; ATTEMPTED PRESERVATION; SECOND AMPUTATION; FATTY ORGANS; DEATH.

Edmund E——, aged forty-seven, was admitted into the accident ward on July 20th, 1880. He was a fly-driver at Chiselhurst, and was thrown from his fly and run over, at 10.30 P.M., on the 19th. A local surgeon bound up his leg and sent him to Guy's. On removing the bandage, a piece of bone was found to have come away. The wound was about two inches long. There was fracture of the lower third of tibia. There was also a graze over the inner side of right patella, about the size of half-a-crown. The right metatarsal phalangeal joint was also a good deal bruised. The left shoulder was tender, but no bruising was to be seen. The tendo Achillis was divided. There was a little crackling up the tubercle of the tibia (emphysematous). Two interrupted side and one back splint were put on, and ice was applied to the seat of injury.

On July 26th the patient complained of heat in the injured limb and a good deal of pain, and he had been delirious during the night. On examining the leg there was a little extravasated blood on the front as high as the knee in the cellular tissue. The wound was on the inner side. There was extensive extravasation of blood in the calf. It was chiefly under the soleus, reaching nearly down to the knee, and lying in a plane superficial to the deep fascia. The tibialis anticus was slightly lacerated. The fracture was of both bones, three and a half inches from the anterior border of the tibia; there was a gap in the under surface of tibia from which the pieces were removed; there was a loose fragment of the fibula attached by muscle only. The posterior muscles were chiefly lacerated. The anterior arteries were not wounded. The internal saphena vein was free, but a good deal of coagulum surrounded it. Around the end of the bones was some granular tissue springing from the muscles. The periosteum reached nearly to the end. Nowhere amongst the muscles or cellular tissue was there any suppuration. There were some fine adhesions between the muscles around the clot. No suppuration round the end of the bones. All the clot looked firm except at one point, where it was grumous near the fracture. End of tendo Achillis was torn; the upper part looked a little swollen. The gap between was not filled up, though within the sheath there was a little new lymph. The ankle-joint was sound. Coagulum in medullary cavity. No pus beyond the clot. There was everywhere much yellow serous fluid. Stokes's supra-condyloid amputation was performed. Next day the patient was partly delirious, and very thirsty. The pupils were contracted, and there was a spasmodic twitching of the muscles. He was perspiring freely. Urine clear, pale, slightly ammoniacal, with no trace of bile or albumen. On the 28th he was quieter. There was a little yellowness of conjunctiva. There was no œdema or redness above the amputation. On the 29th he was restless. Tongue brown and dry; sordes on lower lip. Perspired freely. Passed excretions in bed. He had a peculiar smile playing over face. Urine was brown, with a greenish colour floating on top; there was some sediment; albumen was present; nitric acid gave a slight pink blush. During the afternoon he became suddenly worse, and died at 3 o'clock.

Post-mortem examination.—There was extensive decomposition. The scrotum and face inordinately distended with gas. A great deal of fat in abdomen wall. The organs were all fatty, which condition Dr. Fagge thought had an important influence in causing death. There was no evidence of pyæmia.

BURTON-ON-TRENT INFIRMARY.

SARCOMA OF HEAD OF TIBIA; AMPUTATION; SECONDARY DEPOSIT IN CHEST; DEATH; NECROPSY.

(Under the care of Mr. P. B. MASON.)

T. A——, aged fifteen years, was first seen late in May, 1880. He complained of pain in the left leg just below the head of the tibia, and on the inner side. He had been struck on that spot a few weeks before by a cricket-ball, to which cause he attributed the attack. There was some tenderness over the spot and a slight fulness, apparently due to thickening of the periosteum. The case, in fact, presented all the characteristics of one of subacute periostitis, and was treated accordingly, but without any relief. After having been seen for a short time without any appreciable alteration in the symptoms he was lost sight of until the end of September, when he applied again. The aspect of the case was by this time very considerably altered. At the spot abovementioned there was a distinct swelling of a very elastic character, which had increased rapidly in size. He was admitted into the house, and the swelling daily became larger, and soon exhibited faint pulsation. The general health was good. No swelling of glands in groin, and no dulness could be made out in the chest. On October 2nd the patient was put under chloroform, and a grooved needle was passed through the swelling down to the bone. A bloody serum exuded and small spiculæ of bone could be distinctly felt. The thigh was amputated in the lower third, full antiseptic precautions being observed. The patient made a good recovery from the effects of the chloroform at the time, but towards evening there was considerable retching, great pain in the stump, and some hæmorrhage. The dressing was removed under the spray, when the flaps were found to be much infiltrated and distended by a large venous clot which had formed between them. The hæmorrhage was found to be from the femoral vein which had been divided very obliquely in the operation, and not bleeding at the time had been unnoticed. It being quite impossible to get the edges of the flaps into apposition again, the antiseptics were abandoned, and they were simply bandaged together with gauze bandages, which were allowed to remain on for five days, the discharges soaking through them. The flaps granulated quickly, and the wound eventually healed without any further complication. He was discharged well on November 20th. It is interesting to note that although all the vessels were secured without carbolised catgut ligatures there was no sign of hæmorrhage after the antiseptics had been discarded.

The boy was seen from time to time and appeared to be doing very well. On the 15th of December, however, he complained of great pain in the right side, and on examination presented all the physical signs of acute pleurisy with slight effusion. He was again admitted, but the symptoms did not yield to treatment. The effusion increased considerably; blisters were applied freely, with but little relief. There was also some dyspnœa, which was never very urgent except when lying down. The whole of the right chest was soon distended by fluid, and the advisability of tapping was discussed, but negatived (as the real cause of the pleurisy was strongly suspected) unless the difficulty of breathing became greater. This did not occur, but on the 26th of December, having felt rather better during the evening, the patient died very suddenly.

The necropsy disclosed a large mass of sarcoma at the base of the right lung, binding it down to the diaphragm. The right pleural cavity contained 320 ounces of fluid. The pleura on both sides of the chest was studded with small growths (all adherent to the ribs) from the size of a chestnut to that of a pea. The other organs were normal. No sign of any recurrence in the stump. On microscopic examination the primary growth proved to be a spindle-celled sarcoma, while that in the chest was composed of round cells. The nodules studding the pleuræ were found to have originated in the osseous structure of the ribs.

WINDSOR ROYAL INFIRMARY.

CASES RECENTLY TREATED UNDER A STRICT ANTISEPTIC PLAN.

(Under the care of Mr. HOLDERNESS.)

FOR the following notes we are indebted to Mr. C. Bullock, house-surgeon.

Amputation of Leg.—This operation was done at the lower third, in a man, aged twenty-three, for long-continued and extensive disease of the ankle-joint. Strict antiseptic precautions were observed at the time of the operation, such as catgut ligatures, carbolised silk sutures, india-rubber drainage-tubes, and the usual dressings. The wound was dressed on the second, fourth, sixth, eleventh, sixteenth, and twentieth days after operation. All sutures were removed on the eleventh day, and drainage-tubes on the sixteenth. The temperature the night before the operation was 101·2°, having been so for many nights previously. On the night of the operation it fell to 98·4°, and never rose afterwards. Patient discharged on the twenty-third day after the operation, wound entirely healed, with an excellent covering to the ends of the bones.

Amputation of Leg, at the Lower Third, was performed on a child, for the removal of a useless foot, and with a false joint, about three inches from the ankle, the result of an intra-uterine fracture. Strict antiseptic precautions, at the time of the operation, catgut ligatures, carbolised silk sutures, india-rubber drainage-tubes, and the usual dressings. Wound dressed on the second, third, fifth, eighth, tenth, sixteenth, and twenty-first days. Sutures removed, as required, up to the eighth day, and tubes, which had been gradually shortened, were removed on the twelfth day. The temperature never rose above normal. Patient left the hospital on the twenty-first day, stump quite healed and firm.

Opening a large Abscess on the back of the Thigh, in a man aged forty-five, from which twenty-four ounces of thick offensive pus were withdrawn. The man before the operation had had rigors, and evening temperatures up to 104°. The temperature became normal twenty-four hours after the operation, and remained so. The abscess cavity gradually closed up, and the patient was discharged on the seventeenth day.

Removal of Solid Bodies from the Bursa on each Leg, situated between the tubercle of the tibia and ligamentum patellæ. The ether spray was used on this occasion. The wounds were united with catgut sutures, and free drainage provided. The wounds were dressed on the second, fourth, and sixth days. She returned to her duties, which occasioned much kneeling, on the eighth day, perfectly free from all former pain, which had been caused whenever she knelt for the past year or more.

Removal of Bone from the Surface of Tibia.—A case of osteitis, in which the nocturnal pains had been most severe. A long trial of other remedies having failed, about two inches in length, from the upper part of the internal surface of the right tibia, was removed with gouge and hammer, the periosteum having been previously detached. The wound was left unsutured, and filled with blood clot. At the dressings this clot was carefully preserved. The wound gradually contracted until a line of healthy granulating tissue remained. All pain in the leg ceased immediately after the operation, and the patient left the hospital able to walk without pain, and eager to do her work, on the twenty-seventh day.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Double Facial Paralysis.—Cheiropompholyx.—Tubercular Meningitis.

AT the meeting on the 4th inst. the chair was taken by the President, Dr. BROADBENT, who exhibited a man who was the subject of a double facial paralysis; it was a peripheral paralysis. The man had suffered from headache for a long time, but the history of syphilis was doubtful. If the disease were of central origin, Dr. Broadbent remarked that it was one of a condition of extreme rarity, for that if there had been symmetrical lesion in the medulla oblongata the sixth nerve ought also to have been implicated, but it was unaffected. There was no reaction to the Faradaic current, but there was an exaggerated response to galvanism. The appearance was not characteristic of facial paralysis, because from the affection being bilateral the mouth was evenly balanced between the muscles of the two sides of the face. The expression was solemn and the man was unable to shut his eyes voluntarily, though they closed during sleep. The condition was the result of exposure to extreme cold.—Dr. S. MACKENZIE called attention to the loss of smell and to the facility with which, owing to the symmetry of the affection, the case might have escaped recognition.—Dr. GILBART SMITH noted the fact that the man had lost the power of distinguishing salt from sugar.

Dr. CROCKER exhibited a Case of Cheiropompholyx, or Dysidrosis. The disease began as small vesicles in the palms of the hands, which ran together to form irregular bullæ one inch and half in diameter. He was of opinion that the sweat ducts opened through the middle of the original vesicles. Possibly dysidrosis and cheiropompholyx were really different pathological conditions. The patient, he showed, was a confirmed dyspeptic, whom he was treating on general principles, with the local application of oleate of zinc or lead. Both the hands and feet were affected in large bullous and in small erythematous patches. In reply to the President, Dr. Crocker remarked that the sweat was acid, but the fluid from the vesicles was alkaline in reaction.

Dr. DAY read a paper "On Tubercular Meningitis and the Mode of Treatment." He commenced by asking two questions: 1. At what stage of the disease could its nature be surely recognised? 2. Is its progress affected by treatment? The premonitory symptoms were essentially febrile; then might come on varied grave signs with great rapidity, when perhaps the disease in its early symptoms had been mistaken for typhoid fever, or some other ordinary disease. An abstract was read of five cases. The first was that of a very young child, who had in the course of the disease suffered no sickness. The second case was that of a child nine years old, who had been ill twenty days, but had never suffered from vomiting. The pulse, respiration, and temperature had rapidly mounted just before death. The autopsy revealed general tubercular infiltration. The third case was that of a child two years and a half old. In this case also there had been no vomiting, but there were flushings of the face and convulsions. Early on the day of death the temperature was 99°, but towards evening it had risen to 105°. In the fourth case, a child of four years, there was no vomiting; but in the fifth there had been both constipation and vomiting. Of all the cases this was the only typical one, though the temperature never rose above 101°. Dr. Day did not regard optic neuritis as a great aid in making the early diagnosis. Congestion and haziness of the optic discs might be much more frequently discovered, though it was by no means easy to make a satisfactory ophthalmoscopic examination in an irritable restless child. As regards the treatment of these cases he would rather ask for suggestions than attempt to give any. Cold to the head often gives relief; iodide of potassium he had never found to be of any avail. He thought that the recorded cases of "tubercular" meningitis were really instances of simple inflammation.—Dr. S. MACKENZIE said it was often impossible to make a diagnosis in the early stage. He regarded a high temperature as a sign of impending dissolution. Irregularity of the pulse and retraction of the abdomen were important symptoms. In his opinion a few cases of undoubted tubercular meningitis did recover. Iodide of potassium and mercury were his usual remedies.—Dr. ALTHAUS said that a heightened temperature with a slow pulse were important aids to diagnosis. He advocated cold applications to the head.—Dr. GREEN regarded the pulse as probably the most important aid in making a diagnosis; it was very irregular, both in rhythm and force.—Dr. LEE advised caution in making a diagnosis, for many cases presented but the general and ordinary symptoms of cerebral disturbance. Experience had led him to the conclusion that true cases of tubercular meningitis do not recover. Ptosis was a most characteristic symptom.—Dr. GILBART SMITH mentioned the marked difference in the pulse rate when the child was lying down and when standing up. The ophthalmoscope was of great use in the later stages of obscure cases.—Dr. CROCKER alluded to the ease with which a few tubercles may escape observation on the post-mortem examination.—Dr. DAY briefly replied. In his opinion no case of true tubercular meningitis recovered.

The meeting then adjourned.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Optic Neuritis.

A SPECIAL meeting of this Society was held on the 31st ult., when the adjourned debate on optic neuritis, opened at the last meeting by Dr. Hughlings Jackson, was resumed and concluded, the President, W. Bowman, Esq., F.R.S., in the chair.

Mr. STREATFEILD showed a boy twelve years of age with optic neuritis and enlargement of cranial bones. There was a hard but not tender prominence of the left frontal bone, and the supra-orbital arch appeared depressed. The upper eyelid was œdematous, the levator palpebræ unaffected. The swelling had been noticed for four months, and had undergone but little change. The boy was thin, complained at times of his sight, and had occasional headache, but no vomiting. Vision: right eye $\frac{20}{70}$; left, $\frac{20}{50}$; double optic neuritis: discs swollen and grey, veins engorged, arteries small. After one month's treatment by iodide of potassium vision in right eye was $\frac{20}{100}$, left $\frac{20}{70}$. Mr. Streatfeild presumed there was some growth from the lateral part of the frontal bone extending inwards.

Mr. SEBASTIAN WILKINSON showed a patient with Double Optic Neuritis and Retinal Hæmorrhages.

Mr. STANFORD MORTON showed two cases illustrative of the Co-existence of Normal Vision and Swollen Discs. Case 1. A man with double optic neuritis, vision in right eye, 0; in left, $\frac{20}{20}$, and with presbyopic correction can read Jäger 1. There was a history in this case of a blow on the head, followed by pain and muscular tremors. Ophthalmoscopically no apparent difference in the condition of the two discs. Case 2. A young woman, under observation for two months, with slight asthenopia. Both discs were swollen, but there was perfect vision—viz., $\frac{20}{20}$ in each eye, and ability to read Jäger 1. The case was remarkable for the lengthy duration of good vision with neuritis.

Debate on Optic Neuritis.

Dr. S. MACKENZIE said he spoke as a pupil of Dr. Jackson, and agreed in much that he had said. He also knew of no sign by which a "choked disc" could be distinguished from a "descending neuritis," and admitted the difficulty there was in distinguishing between neuritis due to Bright's disease and that due to cerebral tumour, and showed drawings in illustration. In one case of double neuro-retinitis, thought to be due to Bright's disease, but without albuminuria, the autopsy revealed a cerebellar cyst. In another case of double optic neuritis with syphilis and Bright's disease no coarse change was found in the brain. Another important point was the condition of the optic nerve left after neuritis, and he showed a case where lead-poisoning had been the cause of the neuritis, which, after treatment by iodide of potassium, had entirely disappeared; and another case where striation along the vessels and slight blurring of the discs remained to show the previous existence of neuritis. Dr. Jackson had drawn attention to the existence of optic neuritis without loss of sight. He would say that the majority, or at least one-half, of the cases had no defect of sight, and hence the difference in experience between ophthalmic surgeons and physicians upon the matter. He referred to a case of epileptiform convulsions due to a tumour of the cerebellum with double optic neuritis but no defect of sight. Serious mistakes sometimes arise from want of ophthalmoscopic examination; and he knew of two cases of headache and occasional vomiting put down to malingering, but which proved to be due to tumour of the brain, where an ophthalmoscopic examination would have been of great value; any kind of change in the brain would produce neuritis. As to the manner of its production, Dr. Jackson favours the vaso-motor hypothesis, but had hardly dwelt sufficiently upon the neuritis being due to an extension of an inflammatory process from the brain. He himself had published a case where nothing was found in the brain, but there was corpuscular exudation in the optic nerves without any distension of the nerve-sheath. However, observations were wanted to prove the existence of a continuity of change from the region of a tumour to the optic nerve. Dr. Jackson thought that the fact of some patients complaining of defect of sight before neuritis appeared was in favour of the vaso-motor hypothesis. But the precursory stages of inflammation might lead to the same result, and Dr. Jackson's view that the symptoms of tumour are due to concomitant encephalitis would harmonise with the doctrine that the nerve is involved by extension from the brain or by a general condition acting equally on the brain and optic nerve. Microscopical examinations of the tissue around a tumour were wanted to clear up these points. He agreed with Dr. Jackson as to the great importance of treatment in optic neuritis to preserve sight, and thought iodide of potassium freely given was the best method. Dr. Mackenzie concluded by showing a drawing from a case where there was three years ago well marked neuritis, but now almost normal discs; and another drawing of neuritis from lead-poisoning, which would probably be interpreted as due to renal disease.—Dr. BUZZARD said that it was now many years ago since Dr. Jackson drew attention to the important points that unilateral fits and optic neuritis denoted a new growth involving the brain; and that good sight might exist with optic neuritis. Having also had the advantage of Dr. Jackson's personal instruction in the use of the ophthalmoscope, he was under the same difficulty as Dr. Mackenzie in finding but few points in Dr. Jackson's paper from which he could differ. He had brought down a patient illustrating the first of the above points; a woman who eighteen years ago suffered from pain in the head and failure of sight. She had from that time to this suffered from fits beginning in the left hand. She became blind and her eyes now show post-neuritic changes. He was certain that had this patient (the cause of her neuritis being no doubt syphilis) been examined ophthalmoscopically in the first instance and then treated, she would not now be blind. The profession was vastly indebted to Dr. Jackson for insisting upon this point. He thought that good sight was the rule in optic neuritis. He had never seen optic neuritis with cerebral hæmorrhage apart from tumour or other disease of the brain, nor had he seen it in cerebral softening. Dr. Jackson's hypothesis that the nerve condition was induced by vaso-motor action was, taking all things into consideration, the most probable explanation; but why should the optic nerve be specially singled out? One must either account for its being selected or show that it shares a derangement common to the other cerebral nerves. The optic nerve was anatomically peculiar in being bounded by the scleral ring; but was it a fact that the other nerves were unaffected? Might not a similar change in the fifth nerve often account for the pain in the head which accompanies intracranial tumour; and the vertigo by changes in the oculo-motor nerves? May not the vomiting, the slow pulse, and possibly the occasional occurrence of sudden death in these cases be due to an affection of the vagus comparable to that which in the optic nerve produces the symptom of optic neuritis?—Mr. HUTCHINSON said they should be thankful to Dr. Jackson for having strangled the "choked disc" at last. He would illustrate some of the different circumstances under which optic neuritis arose by mentioning a few cases. One was that of a patient who, two months after having acquired syphilis, complained of dimness of sight. Double optic neuritis was found with abundant effusion of lymph. It lasted six weeks, good sight being retained. There was no cerebral symptom whatever. A young lady, healthy and florid, complained of being blind in one eye; nothing was seen by the ophthalmoscope; but, on the apparently normal eye being covered, the pupil of the affected eye dilated. At the end of a week the disc of this eye was found to be covered with lymph; which cleared away under mercurial treatment. There were no cerebral symptoms in this case. Another case was that of a lady who hurried home from Italy, because whilst visiting the picture galleries of Florence she was attacked with headache, and found that the vision of her left eye was impaired. Mr. Hutchinson saw her on her arrival in England, and found the optic disc buried in lymph. This case also was treated with mercury, and there had been no symptoms of intracranial disease. In view of cases such as these did not Dr. Jackson think that some forms of optic neuritis were primary and idiopathic? It appears probable that there is a form which may be spoken of as syphilitic neuritis, and the forms of neuritis occurring in renal disease and lead-poisoning were primary inflammations of the nerve tissue. Dr. Buzzard's remarks upon the possible existence of other nerves being attacked were suggestive, and explained the sudden occurrence of paralysis otherwise unaccounted for. Did Dr. Jackson think that it was always correct to assume that the vomiting and headache were due to the same cause as the neuritis, and not that the neuritis was sometimes the cause of these symptoms? In all cases where he had seen recovery from optic neuritis the vomiting and headache had been at their height at the time when the neuritis was most intense. Many years ago he remembered a lad coming to Moorfields Hospital totally blind, with widely dilated and insensitive pupils and discs covered with lymph. No symptoms preceded the attack, the blindness coming on suddenly after working at bricklaying on a hot summer's day. There were no paralyses. Mercury was freely given, and good sight was regained; but he did not know whether any cerebral symptoms subsequently developed. These were only samples of many cases which had come under his observation when the first suspicion of the neuritis was raised by the affection of sight itself. Many years ago he had published a paper upon the occurrence of white discs in children who, at some previous time, had passed through a cerebral illness resembling tubercular meningitis. He doubted if so many cases of tubercular meningitis could have recovered, and there may have been encephalitis or meningitis in some of the cases, but others may have been instances of primary optic neuritis. Analogous cases occurred sometimes after the exanthemata. Dr. Waddilove had described cases of optic neuritis following measles; and lately he (Mr. Hutchinson) had seen a girl, eighteen years of age, with pale discs, who had had no brain illness, but when a child had been attacked with measles, which "went in" very rapidly, and she became almost insensible. Probably this was an attack of some form of meningitis or encephalitis with optic neuritis, the effects of which remained in the pallor of the discs. Mr. Hutchinson concluded by expressing the great obligations he was under to Dr. Jackson for his teachings on this important subject.—Dr. GOWERS said he would chiefly speak on the origin of optic neuritis. Anæmia might lead to it. He had recorded some cases in chlorotic girls, and had found the neuritis disappear in the course of two weeks under treatment by iron. This showed that a general blood condition may lead to inflammation of the optic disc. In cases of Bright's disease, in which the optic neuritis exists without retinitis, there may be very prominent head symptoms, and he recalled one case supposed to be cerebral tumour. But the characteristic white dots were present in the retina, and the urine contained a large quantity of albumen. The occurrence of the neuritis and of the cerebral irritation in these cases may be due to the altered condition of the blood. Dr. Jackson had confirmed Mr. Couper's opinion upon the dependence of some cases of optic neuritis upon hypermetropia. When the neuritis is considerable there is hypermetropia; it was so in the cases of anæmia to which he had referred; but the neuritis was more than the hypermetropia could account for, and, moreover, cleared away under iron. The difficulty of diagnosis between optic neuritis from cerebral disease and that from Bright's disease only exists when the neuritis is subsiding, and leaves white spots at the places to which the inflammation has extended. In Bright's disease the white spots are always at a distance from the inflamed papilla, and should be sought for by the direct method. From observation of several cases Dr. Gowers thought that in the early stages the inflamed papilla was much paler in meningitis than in cerebral tumour; but in subsiding neuritis there is pallor of the disc under either condition. He was surprised that Dr. Jackson had not mentioned chorea among the conditions with which optic neuritis may be associated; for he (Dr. Gowers) had given Dr. Jackson as his authority for such association. In one case of chorea examined by Dr. Gowers there was also Bright's disease, and he had seen another case of chorea where there was marked neuritis. As to choked disc, his own observation was opposed to the idea that there was any intensification of pressure at the sclerotic ring; the vessels pass through the ring entirely unconstricted. They become "choked" in the swollen papilla, not behind it. Might not Mr. Hutchinson's cases be instances of retro-ocular neuritis? Some time ago he met with a patient suffering from intense pain in the head, with no loss of sight, and with the least trace of neuritis, which rapidly increased, whilst paralysis of one orbital muscle appeared. These symptoms subsided, but before that the other nerve became slightly affected. Dr. Jackson had put forward the difficulties in the way of the vaso-motor theory. But is there any ground for believing that inflammation ever results from reflex vaso-motor action? The only two instances that occurred to him were renal hæmaturia following catheterism, which might be accounted for by the immediate dilatation of the renal vessels, and not by inflammation; and the other was the occurrence of duodenal ulceration after severe burns, a remarkable phenomenon, the only instance in which actual tissue alteration followed from nerve irritation at a distance. Again, it would be difficult to believe that a reflex effect would be confined to the vessels of the optic disc; it should equally affect the cutaneous vessels, so that were the vaso-motor hypothesis true we might expect an intermitting blush to be produced by cerebral tumour. Herpes zoster afforded no analogy, for the change was limited to the area supplied by the affected nerve trunk. The distension of the optic sheath was an important fact; it was very frequent, and some surgeons (e.g., Mr. Power) had punctured the distended sheath; and it might reasonably be thought to have some influence in the production of the papillary change. The distension of this great lymph channel may intensify a neuritis although it may not cause it. In the case of a child ten years of age admitted with acute cerebral symptoms, old choroiditis, acutely inflamed discs with hæmorrhages, there was abundant syphilitic disease of the arteries of the brain and an extensive hæmorrhage. The optic sheaths were greatly distended, the bones of the skull and orbital plates were thickened, so that the optic foramen was constricted, and this condition probably determined the great distension of the optic sheath. In many cases there was evidence of descending neuritis; definite changes in the optic nerves extending from the brain in meningitis. In one case of tumour of the frontal lobe there was but slight change in the optic nerve, but higher up very marked changes. There is then inflammation around a cerebral tumour, and in the optic papilla (a part prone to inflammation, partly on account of its anatomical conditions), distension of the optic sheath, which may intensify the papillitis, and traces of inflammation more or less marked along the optic nerve to the brain. The change in the nerve-trunk might be barely perceptible, and yet suffice to light up an intense papillitis. May not a like change occur throughout the entire brain, and explain the other symptoms of the tumour? Taking the facts that are known, optic neuritis may be held to be due to (1) a condition of irritation in the brain, (2) distension of the optic sheath, (3) the change reaching the papilla and lighting up inflammation there. But the vaso-motor theory is as incapable of proof as it is of disproof.—Dr. BROADBENT said that optic neuritis was sometimes produced apparently by suppression of the catamenia. A girl who had suffered for two years from vomiting, headache, and double optic neuritis, which passed on to atrophy, was first attacked on the sudden arrest of the catamenia. With the restoration of the catamenia, the headache, vomiting, and a peculiar mental condition ceased. In another case of optic neuritis, no coarse disease in the cranium was found after death; no evidence of inflammation; only considerable ventricular effusion. He believed that all the phenomena of optic neuritis were best explained by optic ischæmia—pressure on the nerve through effusion into its sheath. He had never seen a case in which the disc could be supposed to be covered with lymph; the structures are swollen, and the vessels buried in them. He believed that fluid was forced by intracranial pressure into the sheath of the optic nerve, and that this strangled the disc. In every one of these conditions—in anæmia, lead-poisoning, and tumour—there is increased intracranial pressure. The only reason why neuritis does not invariably occur in renal disease was the existence of very high arterial tension. The two conditions of intracranial pressure and of fluid to be forced into the sheath must be present. Many cases of increased intracranial pressure occurred without optic neuritis; in such cases there is no fluid to be forced into the sheath, or obstacles to its entrance. In some cases of great ventricular effusion the whole surface of the brain is dry and sticky; in such cases one cannot expect to find meningeal fluid. The only case in which he had seen unilateral optic neuritis was one where a tumour was so situated as directly to prevent fluid passing along the sheath. The size of the tumour did not determine the occurrence of optic neuritis; but the amount of vascular disturbance around it. In hæmorrhage there was no great increase of intracranial pressure—the effused blood being substituted for so much cerebro-spinal fluid. Mr. Power had relieved the symptoms of neuritis by incising the distended sheath. He (Dr. Broadbent) had never attempted to distinguish between ischæmia and neuritis. The acceptance of the vaso-motor hypothesis would only increase the difficulties of the subject.—Dr. BRAILEY would draw a distinction between simple swelling or œdema of the papilla and optic neuritis going on to atrophy. He had seen many cases where optic neuritis occurred from local disease—e.g., tumour of orbit. Again, in intra-ocular tumours, such as sarcoma of the choroid or glioma of the retina. Optic neuritis sometimes occurs associated with wound or ulcer of the cornea, the inflammation spreading along the sclerotic to the nerve. Then there were the cases where embolism produced acute inflammation of the optic nerve and resulting glaucoma. These are instances of local causes producing the inflammation which spreads along the fibrous tissues, a strong reason for believing in an inflammatory and not a vaso-motor origin of the condition.—Dr. WALTER EDMUNDS pointed out that the fluid within the sheath was produced by the inflammatory process, and believed that anatomical facts were in favour of there being a descending neuritis—the evidence of inflammation being traceable along the optic nerve as high as the chiasma in cases of tumour and meningitis. The inflammatory process spread along the bloodvessels, and not along the trabeculæ or nerve fibres, for it is confined to the papilla. His own observations led him to believe that in all cases there was some basic meningitis about the chiasma.—Dr. HUGHLINGS JACKSON briefly replied, and after a cordial vote of thanks had been awarded him on the motion of the President the Society adjourned.

ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.

AT the meeting on Wednesday, March 16th (Thomas Edgelow, L.R.C.P., President, in the chair), Mr. W. A. N. CATTLIN drew attention to a courteous letter he had received from the Secretary of the Royal College of Surgeons of England, asking him to correct one or two slight errors into which he appeared to have fallen in his recent address "On the Imperfections of the Dentists Act" when alluding to the licence in midwifery. It would appear that out of the three unqualified persons who were examined for the licence in midwifery, only one (*not three*) received it, and two were rejected. From the Regulations respecting the licence (a copy of which accompanied Mr. Trimmer's letter), he ascertained the fact that candidates who were members or licentiates of other Colleges, or who had passed through a curriculum of education prescribed by Rule VI., were up to 1875 entitled to be examined for the licence in midwifery, so that he was wrong in saying only members of the College could receive it.

Mr. EDWARD BALTLETT read a short paper on the four following cases:—Case 1 was that of a girl aged twenty, with a supernumerary tooth posterior and between the central incisors, and which appeared at the same time as the centrals.—Case 2 was that of absence of the second tricuspid, which was accounted for by the posterior deciduous molar being forced up nearly into the antrum by the closure of the first bicuspid and molar over it. This (the crown of the molar) Mr. Bartlett removed, which felt on exploration like dead bone, being covered with tartar.—Case 3. Two very large supernumerary teeth and a lateral, which he had removed from the mouth of a man, aged thirty-three, who had a third central incisor, undistinguishable from the normal ones.—Case 4 occurred in a young lady, aged nineteen, in which all the permanent teeth were absent, with the exception of the two centrals, two canines, and two molars, some of the temporary teeth remaining in their position.

Mr. HAMILTON CARTWRIGHT made some remarks on the treatment of Rigg's disease, consisting of the destruction of the periosteum of the teeth, absorption of the alveoli, and ultimate loosening and loss of the teeth. He said that it generally commenced in an unhealthy condition of the gums, and that he believed the deposit of tartar to be secondary to the disease; the deposits of the saliva pocketing between the separated gum and the teeth. Of course the first and most important matter was to remove the tartar effectually, but he still held that much might be done by a very, so to speak, "heroic" treatment with the knife and escharotics used alternately. Mr. Hamilton Cartwright then showed a most remarkable case of the Jaw of a Dwarf, about three feet high, and compared the denture with that of the American Midgets. The dwarf was the child of wealthy parents, and grew normally for some months, when the development of its body became completely arrested, whilst that of the head and brain continued to a great extent. The boy is about sixteen years of age and highly intelligent, having recently gained a prize for French at school, and having a great taste for study generally. He walks, however, with difficulty, his head being so much larger than his body. His teeth, unlike most dwarfs, are not deficient as in the case of the Midgets, but consist of a perfectly formed *first* set. In the upper jaw only the first molars had been shed to give place to the bicuspids, which are nearly erupted, whilst the six-year old molars are just appearing. In the upper jaw there is a perfect set of milk teeth without any sign of caries. In conclusion, he wished to draw the attention of the Society to the analogy existing between the teeth and dermic structures in their development, and that, as a rule, both the hair and teeth were deficient in dwarfs; but that in this case the hair was as perfect as the teeth, the only peculiarity in the latter being the persistence of the first denture up to the age of sixteen years.

Reviews and Notices of Books.

Lectures on Diseases of Bones and Joints. By CHARLES MACNAMARA, F.R.C.S. Eng., Surgeon, and Lecturer on Surgery at the Westminster Hospital; Surgeon to the Royal Westminster Ophthalmic Hospital, &c. Second Edition. London: J. and A. Churchill. 1881.

THE present edition of this work appears in a considerably altered form. Instead of being limited to a consideration of diseases of bones as before, Mr. Macnamara has included lectures on diseases of joints, and thus the volume has doubled in size, and we may also add in value and importance. There can be no doubt that this alteration in its scope is in accord with the dictates of scientific reason. Bones are, both physiologically and pathologically, the chief structures entering into so-called "joints"; it is impossible to separate fully the diseases of one from the other, and a thorough comprehension of the pathological changes in bone is one of the most essential, if not *the* essential condition of a sound knowledge of diseases of joints. These lectures are not formal, set, clinical lectures, but are an embodiment of the daily instruction given in the wards, with brief records of cases under observation. Mr. Macnamara goes into the question of the occurrence of epiphysitis more fully than before; he maintains that in young children the actively growing tissue at the line of junction of bone and cartilage is very likely to be affected by inflammation, which, leading to separation of the epiphysis, may extend to the periosteum and medullary tissues, and so cause necrosis; he prefers to consider many of the cases of suppurative periostitis of children as really cases of epiphysitis. Several interesting cases bearing upon this affection are cited. In the lecture on syphilitic disease of bone—which is quite up to date, and describes fully the changes to which Drs. Parrot and Barlow have drawn attention, as caused by inherited syphilis—we have an explanation of the frequent and special affection of the vault of the cranium in this malady. Mr. Macnamara points out that not only are these bones ossified from membrane, but are developed from the epiblastic layers of the embryo, and may be regarded as dermal appendages; also that their affection is an illustration of the fact that syphilis and other constitutional diseases tend to affect certain groups of tissues ontologically connected. The author is, however, mistaken when he speaks of the choroid coat of the eye as developed from the epiblast; it is formed from a part of the mesoblast.

Coming to the lectures devoted to diseases of joints we have only space to notice two points. The first is the author's classification of cases of synovitis into serous, muco-purulent, and purulent. Objection may fairly be taken to these terms, but not to the distinction drawn; and even though it may be convenient for purposes of teaching to show the analogy between, let us say, varieties of conjunctivitis and synovitis, yet if words are to have a meaning it must be inaccurate to speak of any product of synovitis as muco-purulent. Perhaps the terms "simple," "semi-purulent," and "purulent" would serve. Further on, in the lecture devoted to disease of the hip, we meet with an attempt to range the various cases under three heads, those beginning as synovitis, those starting as epiphysitis, and those at first chronic osteo-myelitis of the articular ends of the bones. This is at least a great advance upon the older method of grouping the cases by the bone primarily and chiefly affected as either femoral or acetabular. In our present knowledge, or, rather, want of knowledge on this point, any classification on a pathological basis, however much to be desired, must be received with caution, and it can hardly be expected to command general assent. Moreover, a pathological classification which is nothing more, and cannot be clinically applied, may be interesting, but is wanting in practical value and fails at the test which must ultimately be applied to it. Can we then separate clinically Mr. Macnamara's three groups of cases? Mr. Macnamara says that cases with a slow ill-defined early course and very chronic development are cases of osteo-myelitis; those characterised by severe pain coming on soon after an injury and local heat and fulness of the joint are cases of synovitis; while those cases which occur in quite young children, with severe pain, great constitutional disturbance, early rigors and evidence of suppuration, are instances of suppurative epiphysitis. This distinction appears sound and practical, but the question still remains, are *all* the cases included? Are there not cases of very slow granular synovitis at first indistinguishable from and later on leading to chronic osteo-myelitis? This subject, however, is too large to be dealt with fully here and now. Suffice it to add that the volume before us will doubtless prove acceptable to a large number in the profession, for it is well written, and is a happy combination of scientific and practical surgical teaching.

Experimental Chemistry for Junior Students. By J. EMMERSON REYNOLDS, M.D., F.R.S., Professor of Chemistry in the University of Dublin. Part I. Longmans and Co. 1881.

IN these days of "little books," which are often insufficient, and issued only for the purpose of cramming, it is a relief to come across a really good introductory work written with a high purpose. This volume does not pretend to teach much, but what it does teach it teaches thoroughly. The system pursued by the author is designed to lead the student through a series of connected experiments and to assist him in the interpretation of his results, and also in devising modes of testing the validity of the conclusions drawn from them. So that whilst acquiring a tolerable acquaintance with facts the student receives a certain amount of training in purely experimental methods. This is the basis on which all scientific training should rest; and no learner ought to be permitted to proceed to the higher branches of study till the A B C has been thoroughly mastered. We wish this little volume every success. For candidates preparing for examination in elementary chemistry at the matriculation at the London University or the Oxford and Cambridge local examinations it will be found a useful guide.

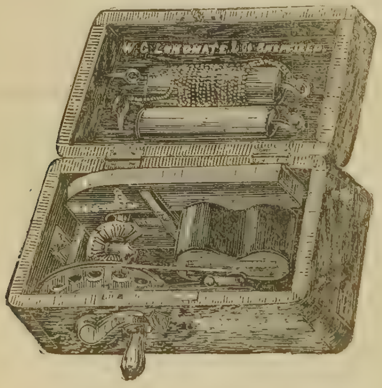
Lectures on Syphilis. Delivered at the Harveian Society, December, 1878, by James R. Lane, F.R.C.S., Surgeon to St. Mary's Hospital, and Lecturer on Surgery; Consulting Surgeon to the London Lock Hospital. Second Edition. London: J. and A. Churchill. 1881.

The fact that the first edition of this book has been out of print for some time is sufficient evidence that the lectures meet a real want. They are a simple statement of the main facts about syphilis which may be considered established. From the view that all forms of venereal disease are modifications of one great malady a good deal of confusion has arisen, and the reasons for separating them into three distinct classes are clearly given, as well as important facts in reference to the infective power of syphilitic fluids of different kinds.

New Inventions.

POCKET MAGNETO-ELECTRIC MACHINE.

A miniature Magneto-Electric Machine, constructed by Messrs. W. C. Longmate & Co., of Arundle-street, Sheffield, has been brought under our notice by Dr. C. Nelson Gwynn, of Sheffield. Some of the improvements were suggested by Dr. Gwynn, but the mode adopted for carrying them out is due to Messrs. Longmate and Co. The motion and multiplication of speed and power are on a new principle. There are three beveled mitre cog-wheels, one of which is fixed to the magnet, one fast to and revolving with the band-wheel, and one fast to the shaft turned by the handle. These, combined with a fast and loose shaft or spindle, become so manipulated, that, although the number of teeth in the cog-wheels is the same, yet the driving-wheel is propelled at twice the speed of the handle and shaft. The reason of this is that during the revolutions of the shaft in a rectilinear direction there is also a transverse revolving property in the centre wheel which turns the driven cog-wheel twice round. By the application of this principle a very small and light pocket magneto-electric machine has been obtained, which possesses ample strength and is worked with considerable ease. The magnets are nickel-plated to prevent rust. The machine answers exceedingly well, and will be a great boon to practitioners, being easily carried in the hand, and therefore more likely to be available on an emergency than the larger instruments in common use.



W. C. LONGMATE & CO. SHEFFIELD

HYGIENIC SPONGE-BATH.

A very useful bath is made by Messrs. Groom and Co. It is so constructed as to provide a stage on which the person using it may stand out of the water, supposing he wishes to use either warm or cold as a lavement while avoiding the immersion of the feet. There is a well in the bath for the water, from which it can be dipped by sponge or bowl. This bath will prove most acceptable for general purposes, and is likely to be peculiarly useful for special purposes.

DISINFECTANT HOSPITAL BLANKET.

Acting upon a suggestion first made some years ago in The Lancet, to the effect that paper should be used in the construction of bedclothes, Messrs. Henry and Leigh Slater, of Manchester, have produced a cheap blanket of which the staple material is paper. It is perforated for ventilation, which may or may not be necessary—we are inclined to think not. The blanket is not altogether noiseless, as it is stated to be; but may be readily made so by a little manipulation, or would be so at the outset if different paper were employed in the manufacture.

THE CATGUT LIGATURE.

To the Editor of The Lancet.

Sir,—In your report of the meeting of the Royal Medical and Chirurgical Society on February 8th, some doubt is thrown on the power of a catgut ligature to sever the middle and inner coats of an artery. One speaker says, "if they (viz., the ligatures) had not yielded the coats would have been completely divided." I have had considerable experience in the experimental ligature of healthy arteries in their continuity by carbolised catgut of average calibre, and have always found that with a legitimate amount of force the middle and internal coats were thoroughly divided, the solution of continuity taking place at once, and not after a certain interval; an observation that seems to prove that any subsequent yielding of the ligature is of no importance—as far, at least, as the mere division of the arterial coats is concerned. The belief was also expressed, that "if the inner coat were not divided no clotting would ensue," and in your annotation you say, "If these coats were not divided there was nothing to excite the formation of a thrombus." I can assert from observation that if a healthy artery be compressed in its continuity by a flat-bladed instrument, such as Dieffenbach's clip, a fairly firm clot forms above and below the point of pressure in less than twenty-four hours, though the walls of the vessel had merely been brought into apposition without being wounded. As the clot forms so quickly, and has acquired a certain degree of firmness before suppuration has begun in a septic wound, it is rather difficult to understand how antiseptic precautions can have any deterring effect on the thrombus, in its early existence at least. The marked differences in septic and aseptic cases belong to a later period. Whether the final occlusion of the vessel is brought about by changes in its coats, or by organisation of the clot, or whether it is shared in by both, is a question too wide and difficult to be discussed at present; and I am merely desirous of stating my opinion, founded upon experiment and dissection, that catgut ligatures can be depended on for severing the middle and inner coats of an artery, and that, however advantageous this severing may be for the ultimate obliteration of the vessel, simple compression, and not a wound, is all that is necessary for the formation of a thrombus.

I am, Sir, your obedient servant,

Poona, March 16th, 1881. E. D. Mackellar, M.B.

THE LANCET.

LONDON: SATURDAY, APRIL 16, 1881.

THE long-expected Naval Medical Warrant has at last been published. It fulfils the promise made by Mr. TREVELYAN of a scale of pay somewhat higher than that granted to the army medical officers, "in order to counterbalance the disadvantages of the two services." But we are doubtful whether in other respects the changes introduced by it will be deemed altogether satisfactory by the department. The principle of compulsory retirement of administrative officers at the age of sixty, as in the Army, has been adopted, but in addition to this they are to be placed on the retired list at any age if they have not served for five years, without any reservation as to their non-employment being compulsory or voluntary. The examination of surgeons previously to promotion to the rank of Staff-Surgeon and after completion of eight years from date of entry, is still retained, though abolished in the Army. No grade has been established corresponding to that of Brigade-Surgeon, but "in all matters wherein the Army and Army administration are concerned, Fleet-Surgeons to rank with and as Brigade-Surgeons." We confess that we are at a loss to understand why Fleet-Surgeons, who are in all respects on a footing with Surgeons-Major of twenty years' service in the Army, the rank being granted to all Staff-Surgeons "on completion of twenty years' service," should take precedence of their military brethren, but we presume it is one of Mr. TREVELYAN'S sops "to counterbalance the disadvantages of the two services." It can be of very little advantage in any way. Gratuities are to be given to Surgeons and Staff-Surgeons who retire before completing twenty years' service, and these increase in amount every four years, instead of five as in the Army. These gratuities and the rates of retired pay after twenty years' service appear to be nearly identical with those of the Army Medical Department; but we observe a note as to the retired pay of Fleet-Surgeons which requires explanation. It is attached to all the rates for that grade. "To obtain this rate an officer must hold the commission of Fleet-Surgeon." Is it possible to be a Fleet-Surgeon and to be placed on the retired list as such without holding the commission of that rank? If so, under what circumstances may this happen? If not, what is the meaning of the note? All officers on the retired list under the age of fifty-five will be liable, as in the Army, to be called upon, till they attain that age, to serve in time of declared national emergency, in a rank not lower than that held on retirement. With a view to diminish the hardship arising from compulsory half-pay, the Warrant allows time on half-pay to count as one-third service for increase of retired pay, but not for any other purpose. It is to be regretted that the authorities did not see their way to make arrangements for the abolition of the system of half-pay on a ship being paid off, by employing the medical officer in one of the naval hospitals till his services were again required afloat. Provision is made in the Warrant for an allowance "to officers giving the course of instruction to Surgeons on first appointment to the Naval Service: to a medical officer of Haslar Hospital, £150 a year; to a junior medical officer of the same hospital assisting him, £50 a year." We cannot but think that the withdrawal of naval candidates from Netley is a grievous mistake as regards both the interests of the Service and those of the young officers. The plan now proposed was tried many years ago at Haslar, and we have reason to believe was a complete failure. That a system of effective sanitary and special teaching, such as has been in force for many years and still is most successfully carried out at Netley, will be introduced at Haslar we do not believe. It has been suggested that the withdrawal has been decided upon in accordance with "representations made by naval officers, who thought that association with military medical officers at Netley tended to make the naval doctor discontented with his position and prospects." If this be so, the authorities at the Admiralty have taken a false step. The Service will undoubtedly deteriorate in efficiency from the loss of the special instruction given in the Netley School, and this will react in the way of causing the better class of medical students to hold back from entering the Naval Service. We are afraid that these half measures of the Admiralty will have but little effect in increasing the number of really good candidates for the Department, and that the new Warrant will influence few to come forward as candidates but those who consider money to be the only, or at least the most important, consideration. As the Warrant states that existing regulations as to relative rank are to remain in force, we presume medical officers will be entitled to "cabins according to their relative rank." We have on previous occasions called attention to the fact that the orders of the Lords of the Admiralty on this point are often practically ignored by captains. We would therefore suggest to Mr. TREVELYAN that if he desires any degree of success to attend his new Warrant, he should take measures to enforce this rule, and to remove from the minds of medical officers the strong feeling of injustice which exists in consequence of this permitted violation of the Admiralty Instructions.

◆

"WHY may we not meet professed homœopaths in consultation?" is a constantly recurring question, to which recent events have given an unusual degree of urgency and importance. The answer is a dual one, and apparently paradoxical. We decline to have professional intercourse with professed or reputed homœopaths for one or both of two reasons—either because they are believers in a method of therapeutics which is at once fantastical and absurd, or because they are *not* believers; in other words, either because they are true disciples of HAHNEMANN, or because they are *not*. In one instance the objection is scientific, in the other it is ethical. Despite the prevarications and protestations of those half-hearted professors of homœopathy whom HAHNEMANN and his stricter adherents have denounced by the name of "mongrels," homœopathy is logically Hahnemannism or nothing. From the rules laid down by HAHNEMANN, there can be no material departure without a practical abrogation of the doctrine of homœopathy itself, and with it of the so-called *Law of Similars*. This cannot fairly be gainsaid. A recent exponent of pure homœopathy said: "HAHNEMANN discovered founded, and elaborated a system of healing by medicines; to this system he gave the name of *Homœopathy*. In his 'Organon' he gives the plainest and most minute rules for the practical application of his teachings, and he challenges the medical profession to put his teachings to the test. It would seem, therefore, a very simple matter to define homœopathy; it would seem also self-evident that, while every physician has a right to practise that system of medicine which he deems best; on the other hand, no one has a right to call himself a homœopathician who does not firmly believe in Hahnemann's practical rules, and strive in every case to carry them out to the best of his ability; and it would seem only consistent that the name of homœopathy should not be appropriated to any other system than that to which Hahnemann gave it; yet that which would appear to be self-evidently just and true has not been followed, and Hahnemann's fundamental rules are daily violated by those who falsely call themselves his disciples." This is, at least, an intelligible, if not an intelligent, position. Pure homœopathy differs from scientific medicine by claiming to be a complete and final system of therapeutics, based on constant and universal laws. These laws, as defined by Hahnemann, are chiefly two: First, the Law of Similars; and second, arising out of this, the law of dynamisation of medicines. It is not now necessary seriously to combat either the fanciful hypothesis on which the supposed law of similars is based, that "disease is a spiritual dynamic derangement of our spiritual vital principle," nor the extravagant notion that "dynamisations" of drugs "are real awakenings of the medicinal properties that lie dormant in natural bodies during their crude state, which then become capable of acting in an almost spiritual manner upon our life; that is to say, on our percipient (sensible) and excitable (irritable) fibres." This has been already accomplished by the unanimous condemnation of scientists, philosophers, and practical physicians. It is enough for our purpose to call attention to the fact that obedience to the law of similars has led homœopaths to give dilutions of bugs "to cure the inflammation arising from bug-bites," cholera evacuations for the cure of cholera, and the expectoration of phthisical persons for arrest of consumption; and that the belief in "dynamisation" has carried some of the disciples of Hahnemann to the last stage of impudence or imbecility of claiming to have obtained distinct results, not only by means of olfaction or smelling globules containing the decillionth of a grain of a drug, as Hahnemann asserted, but also by means of medicines contained in *closed* vessels held in the hand. These ridiculous pretensions can have no place in scientific medicine, and, therefore, practitioners of scientific medicine can have no professional association with those who advance them. The objection to a profession of homœopathy is, however, in the present day ethical rather than scientific, because the scientific fallacy has been for ever exploded. Few professed homœopaths nowadays owe allegiance to Hahnemann, still less do they accept homœopathy as a complete system of therapeutics. It will be remembered that about four years ago the Vice-president of the British Homœopathic Society, speaking for himself and a certain section of his colleagues, wrote: "We admit, first, that the views expressed by Hahnemann are often extravagant and incorrect; secondly, that Hippocrates was right when he said, 'Some diseases are best treated by similars and some by contraries,' and therefore it is unwise and incorrect to assume the title homœopathist; thirdly, that although many believe that the action of the infinitesimal in nature can be demonstrated, its use in medicine is practically, by a large number in this country, all but abandoned." (See The Lancet, June 2nd, 1877, p. 817.) The plain meaning of this statement is that the law of similars has broken down, and that "the homœopathic therapeutic maxim" of infinitesimal doses, which Hahnemann alleged was "not to be refuted by any experience in the world," is false. The retention of the name of "homœopath" by a medical practitioner under such circumstances is, therefore, misleading, if not actually unjustifiable, since it has no scientific or logical significance. Those who persist in retaining the name have themselves to blame if they are said to do so for the purpose of attracting a certain section of the lay community. Pure homœopathy has been condemned by the best minds as false and absurd, and without any scientific sanction. We cannot consult with the consistent homœopath (if for no other reason), because his notions of pathology and therapeutics are fundamentally contradictory and antagonistic to ours; nor can we consult with the professed homœopath, though he may occasionally practise according to the principles of scientific medicine, because he employs a name that, in his case, possesses no scientific meaning, and is used for sectarian purposes.

◆

Continuing our observations upon the question of "Blood Diseases" and the "Germ Theory," commenced in our issue of the 2nd inst., we now proceed to the consideration of "Diseased Germs." Before entering, however, upon our more immediate subject, it is well to refer to certain known facts in the natural history of germs—because upon these much of our reasoning in respect to diseased germs must be based. To begin at the beginning, then, we may assume that all animal and vegetable individual life begins in a germ. Whether in the higher animals this germ is supplied by the male in the spermatozoon, or by the female in the ovum, or by a conjunction of both, it is not essential to our purpose to decide. This primordial germ is endowed potentially with the capacity for forming all the structures of varying character of which the fully formed individual consists—blood, skin, bone, hair, teeth, muscle, &c., each in its own place and proportion—to the extent that the mature individual, exactly in size, weight, shape, &c., follows the archetype of its race; but beyond this conformity in all parts, it has impressed upon it, and passes on to the individual made up of its successive generations to a remarkable extent, the physical and structural specialities of its parents. It is impossible to see in this germ of different animals any distinction, still less in different human individuals. Yet does each germ somehow through its long succession of generations and formations of organs pass on more or less of the characteristics of its parents, not merely of colour in hair and eyes, in shape and feature, but of temperament and quality of the organs into which it is differentiated, and of some of the psychical endowments—its highest and its most exalted perfection; the parents are indeed even more the foreshadows of the child than "the child is father of the man." Not more certainly will the germ of the negro develop into a negro with a black skin, than the germ of a negro and a white develop into a mulatto. But this is not all. The sins of the fathers truly cling to the children to the third and fourth generation, and there are unhappily still so many diseases of hereditary character that we must allow that just as the germ has impressed upon it more or less of the mental and bodily characters of its parents, so has it the morbid or diseased characters, which it likewise passes on to be more or less evidenced in the future and more or less matured individual. We might fairly argue that the germ in such case was diseased. We have at hand, however, an obvious instance. A syphilitic father, with no present outward evidence of syphilitic disease, impregnates a pure mother, and a child is prematurely born covered with syphilitic eruption; a second pregnancy follows, and the child is born mature but dead; a third, and the child is born mature and apparently healthy; the only symptoms in the mother being during the first pregnancy a scurfiness of the scalp or falling off of the hair. Can we but believe that the germ of the father, or his portion of it, impressed diseased qualities on the resulting germ-development, which involved the morbid conditions of syphilis in, and the premature death of, the fœtus? As to the father, the first link in this chain, the matter discharging from an infecting sore coming in contact with an unprotected or denuded surface, produced an altered action in the growth and development of the surrounding cells, the result of which is destructive ulceration instead of healing. The elements from this sore are conveyed to the nearest lymphatics; here they produce morbid action with abscess of the gland, the discharge being inoculable,—or the infected cell-elements of the gland pass on till they reach the circulating blood, when the individual becomes or is syphilised—that is to say, the morbid influence pervades his whole body, causing alteration from healthy growth and normal structures in numerous parts and tissues with altered properties, as we have seen, even in the sperm-cells. That the morbid effect must be impressed on the cells and germs seems incontestable, because it must be particulate, as we have shown from previously recited experiments; nor, indeed, can we conceive it to be in solution in the fluid of the blood, ever changing by additions and subtractions as this is, and yet lasting as the morbid effect does. However, were the poison in solution in the fluids of the blood its action must be of chemical nature, a supposition set aside by some experiments of Professor LISTER, who showed that by using almost infinitesimal portions of infecting fluid, but in equal quantities, in some cases infection followed, and in others not. The chemical effect must be uniform, but as the cells vary in quantity in the portions of fluid, success might reasonably be expected to follow in those portions only which contained cells and germs, and not in others which in all probability would not.

Nor is there any difficulty presented in the passage of these cells or germs throughout the body. It is a well established fact that the colourless corpuscles and leucocytes of the blood pass freely through the walls of capillary vessels, and take an active part in the increased proliferation of cells in and around an inflamed spot; but further proof of the possibility of such passage is afforded by the transmigration of the germinal forms of many of the entozoa, and their development in situations they could only have reached through the bloodvessels. Again, we see in many instances, as mentioned in regard to syphilis, as soon as the local affection is established, the next manifestation is in the nearest lymphatic gland. This gland becomes affected, and its leucocytes entering the blood-current pass it on to the system generally, or, as is frequently the case, to form secondary deposits. Sometimes, however, we see infection of the system aborted by the formation of an abscess in the gland closing the further passage of the diseased cells into the blood or system, the matter formed in and discharged from this abscess being itself imbued with the poison, and capable of inoculating the individual or others, for in this case the individual is not protected. A very interesting illustration of this fact was brought to light in the researches of TOUSSAINT and others on the fowl cholera poison—that of anthrax. It was seen that when the contagium was cultivated, and portions were inoculated, in many instances abscesses formed, the animal in such case showing none of the general effects of the poison, only the abscess. If the animal were reinoculated, even from the contents of his own abscess, and no fresh abscess formed, he then manifested all the symptoms of the disease, and, moreover, that when the abscess discharged it was inoculable to others, for even if the discharge came in contact with the food of fowls it produced in them the disease in its entirety.

So many diseases have been proved by experiment to be inoculable by the blood of the infected that we need hardly quote instances, but there are others again in which the discharge from one mucous membrane produces a like specific inflammation in another—as, for example, gonorrhœa and gonorrhœal ophthalmia; but in this instance we seem to approach the edge of the circle in our classification, for slight as is the constitutional affection in gonorrhœa as compared with that of syphilis, it is yet indicated in gonorrhœal rheumatism, and its proneness to induce chronic joint disease, unless, indeed, we consider this, like scarlatinal rheumatism, merely sympathetic or pyæmic. It is, again, a curious fact that we observe in certain of these diseases a tendency especially to affect particular parts, as if they were the foci from which the poison was most easily passed out of the system, and that not only in particular membranes or tissues, but in special parts of such tissues. Not to go into the matter generally, we may mention the salivary glands in mumps, the intestinal glands in typhoid, the throat and tonsils in scarlatina, the nasal membranes in glanders, the salivary glands in hydrophobia, whilst others again, as skin diseases, manifest a decided tendency to symmetrical distribution. We must remember also how prone all developments in any situation are to return to their primal condition under morbid impressions, in some cases, for instance, the proliferating cells return to their embryonic form, in others to a state quite different from the tissues around, in others exactly like them; in some cases, in fact, the inflammatory product is a simple hypertrophy, in others it consists of heterogeneous formations. In thus insisting, however, upon the importance of the germ element in so many diseases, and subsequent investigations will show it to be far more extensive, we do not in the least ignore the effects of morbid or diseased blood itself. The very diseases we have most frequently alluded to are, indeed, characterised by such conditions as have caused them to be classed as blood diseases, nor can we imagine that so all-important a fluid—the reservoir of all pabulum of growth and development, as well as the all-pervading current through which is supplied the oxygen necessary to the continuance of vitality, and through which all the interchanges necessary to the production of vital endowments are effected—can possibly be unaltered by the presence in it of septic elements from without, still less by septic conditions of its essential organisms. On the contrary, we believe that the more or less severe constitutional effects of the poison in the exanthemata are due to the action of the septic germs on the cell organisms of the blood; and further, that the "typhoid conditions" that so often follow these, after the specific effects of the contagion are passed, even sometimes after their elimination has been effected, are due to the altered conditions of the blood perhaps more than that of the cell organisms themselves. We see a case of scarlatina, for instance, pass through its regular course with no very acute symptoms, and no or very slight throat affection (certainly no ulceration), yet a fortnight or three weeks afterwards, when even desquamation has ceased, typhoid symptoms set in with all the conditions of grave blood infection, eventuating in scarlatinal rheumatism, or purulent effusion into the pleura or pericardium, or abscess in the lungs. This can hardly be a reinoculation of the specific poison of the disease, and if not, to what shall we ascribe it but to either the morbid condition of the blood cell-organisms, or to a changed condition of the blood effected in it by the action of the specific *materies morbi?* Do we not know also that there are certain conditions in which the blood is so changed as to be peculiarly susceptible to morbid influence? for example, the puerperal condition. BRAXTON HICKS has shown that in 65 per cent. of a large number of cases puerperal fever was due to exposure to septic influence. Does not the surgeon know that to operate on a patient suffering from albuminuria is to expose him almost certainly to erysipelas or pyæmia? Does not the diabetic condition of old people induce carbuncle and abscess; hæmorrhage a tendency to phlegmasia dolens? Nor is our faith yet abolished in respect to diatheses and constitutional conditions as manifestations of blood disease. We well know how weak and stunted our plants are in poor soil, how they dwindle in confined space and overcrowded greenhouses, and how soon they become the prey to blights and parasites. So exactly of children reared on scanty food in close rooms, and with limited hygienic advantages; their development is imperfect, physically and morally; they are wanting in stamina, and are prone to degeneration. Their cell formations, and therefore their organs and tissues, are not complete and healthy because their blood condition is insufficient and imperfect; hence, as well as to inherited conditions, they are more affected by the, so to say, necessary diseases, and more inclined to manifest those constitutional states which accompany depraved organisations, and which are the starting-points of consumption in very many cases, if not of tubercle. Cell organisms ill-formed and of low vitality send as their product and detritus morbid matter prone to caseation to the lymphatics and blood; these contaminate the leucocytes of the lymphatics, or induce disease of a joint. The resultant morbid germs are arrested in the capillaries of the lungs, just as those of pyæmia, and thus the patient becomes phthisical by self-infection. In pyæmia we have a very widely significant example, for it certainly is in many instances contagious; witness its spread amongst contiguous surgical patients and in our lying-in wards. It seemingly often occurs, apparently without contagion, as the result of a simple accidental or surgical wound; and it also occurs, seemingly without contagion, on any break of surface. Though bacteria are found in the blood of pyæmic patients, the same are met with in that of those who are not so; there is grave doubt, therefore, of its bacterial origin; whilst the constant presence of inflammation products and of germs imbued with the characters of the local inflammation from which they pass, and the consequent constant formation of embolism and thrombosis, undoubtedly giving rise to the secondary deposits, seem to point unmistakably to its dependence on altered and diseased blood germs.

It is still a moot point with many whether cancer should be considered a constitutional disease, and as such more or less hereditary. For ourselves, we can see no difficulty in holding it to be so, bearing in mind the facts to which we have alluded in respect to syphilis. Why should not cancerous, strumous, and other tendencies be passed through the primordial germ of an individual as well as syphilis? All strumous children do not die of phthisis, and all syphilised patients do not suffer from tertiary symptoms. All the offspring of gouty parents do not manifest gouty conditions. Why expect all born of cancerous parents to have cancer? What first causes its development in any particular spot we cannot say, but it is certain that at first cancer seems to be simply a formation of embryonic tissue, like that seen in any inflammatory process. Soon, however, in differentiation, the specific characters of the growth appear. Shortly the nearest lymphatics are involved; and then, the cell organisms of these being altered, secondary deposits occur. We have often thought that the old experiments of HUNTER, the transplantation of cocks' combs, and the modern practice of skin-grafting, throw much light upon the germ theory. If epithelial organisms can be taken from one individual and be made to grow on and form part of another, retaining even their special characters; if the cells from the urethra imbued with the specific characters of gonorrhœa can produce gonorrhœal ophthalmia; if the syphilitic father can through the sperm elements transmit the disease to his offspring, and, as shown in the previously quoted experiments of TAPPEINER, the cell germs in the sputa of phthisical patients, when inhaled in the form of spray, induce this disease in dogs,—why should not cancer be similarly transmissible? That in some cases it is so, by apposition as in skin-grafting, is apparently shown in the frequent instances in which with cancer of the tongue we find patches of the same on the cheeks; and with epithelioma of the cervix uteri we notice the same on the contiguous vaginal surfaces that come into contact with it, for these appear so disconnected with the original disease that they cannot be regarded as secondary developments in the ordinary sense, and their occurrence is explicable only on the ground—for which good reason has been shown—of direct transplantation of diseased cells and germs. The whole question is as wide as its influence on medicine and pathology, as well as surgery, may prove to be extensive; and we have thus, however incompletely, given our reflections upon it, that the subject may have that place in the current thought of the day which its importance seems to us to demand, and as suggestions for its application as occasions arise.

◆

THE *London Gazette* of the 5th inst. gives in detail the new statutes for the University of Cambridge, drawn up by the Commissioners appointed under the Universities of Oxford and Cambridge Act, 1877, and which are to be submitted to Her Majesty, and if approved come into force on the first day of January, 1882. The general effect of the new statutes will be to strengthen and extend the professorial teaching at the University, as well as improve its financial condition. For this purpose the colleges are to be placed under contribution, each of the colleges having to pay to the University chest every year a fixed percentage on its income. This, in the aggregate for the first two years will amount to not less than £5000; in the three subsequent years, to not less than £10,000; and so on, till by the year 1896 the annual income of the University will be from this source not less than £30,000. In addition, the colleges have to provide professorial fellowships, some of which are assigned to particular professorships, as, for instance, the Regius Professor of Greek to Trinity College, the Dixie Professorship of Ecclesiastical History to Emmanuel College, and Professorships in Law and Medicine to Downing College. The other professorial fellowships not assigned to any particular fellowship are twenty-seven in number, of which Trinity College provides five, St. John's five, King's four, Caius two, and the other colleges, with the exception of Downing and Emmanuel, which have special professors assigned to them, one each. In addition to this large increase of the professorial power of the University, the endowments of existing university professorships are to be increased, and three new university professorships created—viz., Physiology, Pathology, and Mental Philosophy and Logic. The professorial chairs are handsomely endowed, the Regius Professor of Physic receiving £700 per annum, the Professor of Chemistry £850, Anatomy £600, Physiology £800, and Pathology £800. The occupants of the last two chairs, however, are debarred from private practice. Again, in connexion with the departments of study for which special boards of studies are instituted, a body of teachers called Readers are to be appointed, each of whom will receive an annual stipend of £400. A certain number of these Readers will be assigned to the Natural Science department and the chairs of Anatomy and Pathology. Their appointment, however, will no doubt depend to a considerable extent on the number of students attending in any given department. The University, moreover, is to have power to appoint lecturers on any subject not immediately connected with any special board of studies for such time and under such conditions as may from time to time seem desirable. The increased resources of the University will also provide for the erection of museums, laboratories, libraries, lecture-rooms, on a more comprehensive scale than they have been hitherto able to afford. Lastly, it is intended to devote some portion of the University revenues in grants of money for special work in the way of research, and for investigations conducted in any branch of learning or science connected with the studies of the University. The scheme is a noble and comprehensive one, and the benefit it will confer on our profession and on science will, we believe, be immense. An increasing number of students will be annually attracted to the University: those of promise to compete for scholarships and other rewards now so liberally thrown open to students of medicine; whilst the more ordinary student will be glad to avail himself of the practical training the University laboratories will afford, and which, if the scheme now introduced be carried thoroughly into effect by the appointment of efficient teachers—and Cambridge in this respect has been hitherto most fortunate,—will be exceptionally great, if not beyond the possibility of attainment elsewhere. Apart from the educational advantage, the gain in another direction will be considerable. One of the great drawbacks in the life of the medical student at our London hospitals is its almost complete isolation from other interests and objects; so that when the time comes for him to engage in the active duties of his professional career, he finds himself at a disadvantage, because he has had no opportunity of acquiring that knowledge of the world which contact and exchange of ideas with men engaged in other pursuits and studies can alone give. A few years spent at the University, as a prelude to the completion of his medical education in London, will be invaluable to him, by bringing him in contact with men training for other professions or occupations in life, and thus extending the range of his ideas and enlarging his sympathies, besides furnishing him with valuable friendships and an entrance into a wider social sphere than is usually possible for the metropolitan student.

Annotations.

"Ne quid nimis."

SIR WILLIAM JENNER, PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS.

THE election of Sir William Jenner to the important office of President of the Royal College of Physicians will give great satisfaction to the profession at large. This distinguished physician has long been recognised by the general consent of his brethren as the head of the profession. Sir William is wrong in regarding the esteem felt for him as a tribute to the position in which "accidental circumstances" have combined to place him. He has been thrust "in the sunlight," but while the fierce light brings out the defects of an imperfect object, it has displayed the professional character of Sir William Jenner in a way to command the respect and regard of his keenest critics as well as his most ardent admirers. This selection for the Presidency of the College reflects honour on that institution, and may well be the harbinger of a new era, a renewal of which the old corporation stands greatly in need. The choice is the more significant seeing that it was made, almost unanimously, after a "personal explanation," in which—following the extraordinary statement made by Dr. Quain with respect to his co-operation with Dr. Kidd in the treatment of the Earl of Beaconsfield—Sir William Jenner announced that he too had been asked to meet Dr. Kidd, and he positively declined. "If then," continued Sir William, "Dr. Quain be right, it is I who deserve the censure of the College." The vote of the Fellows, which gave Sir William Jenner more than twelve times the support accorded to the candidate next below him on the poll, was the answer of the College to this appeal.

It is not Sir William Jenner who has done wrong in declining to meet a reputed homœopath in consultation, but Dr. Quain who has erred in consenting to act with Dr. Kidd! No notice of the question of ethics having been given, and a discussion being impossible, this was the only form in which judgment could be expressed. It is a judgment which will be endorsed by the profession as a whole; and the election of Sir William Jenner to the Presidency of the College is the more honourable, and has the greater significance, because it was accomplished at the conjuncture and in the manner described.

THE CASE OF THE EARL OF BEACONSFIELD.

THERE are features of medical interest in the case of the Earl of Beaconsfield to which it is worth while to allude; but first let us explain that there has been no foundation for the statement that Sir William Jenner met Dr. Kidd in consultation; on the contrary, Sir William expressly declined to do so. There was nothing personal in this refusal. The course taken was that to which every practitioner of scientific medicine must have felt himself impelled. No grounds exist for consultation between the ordinary physician and the professor of a particular school. Medicine is not a science which admits of sectarian views. If two mariners, one of whom believed the earth to be a flat disc, while the other held the commonly received hypothesis of its spheroidal form, were asked to act together in navigating the same ship on a voyage round the world, how could they co-operate? We do not *wilfully* refuse to meet homœopaths; we simply decline because it would be a grim farce and a practical imposition to do so. The result must be a failure of justice to the patient, which may jeopardise his prospect of recovery. The course which practitioners should pursue in an emergency of this kind is very clear. They are not acting rightly in causing the delay of possible relief. They are not called upon, nor is it expedient, to postpone action until they have consulted professional friends. We can scarcely conceive of a more undignified procedure than that which Dr. Quain confesses to have adopted when he delayed obeying the summons he received to the aid of the Earl of Beaconsfield until he had visited or communicated with the then President and several Fellows of the College of Physicians. The call of duty should be instantly obeyed; and the physician, being on the spot and ready and willing to render his services, should claim to see the patient *alone*, or throw on the friends the onus of declining to permit him to do so. This was not, unfortunately, the course pursued by Dr. Quain in the case of the Earl of Beaconsfield, but there will, we think, be no question in the mind of the profession that this is the course which ought to have been taken, and which alone could be defended or approved. What took place at the second visit of Sir William Jenner to Lord Beaconsfield may be stated as follows. In consequence of Lord Beaconsfield's weak state and general illness, it was impossible for those about him to explain any matter to him, and any agitation might have proved fatal. Lord Beaconsfield himself wished much to see Sir William Jenner, but he had remarked on Dr. Kidd's absence from the room when Sir William, having received the Queen's special commands to visit Lord Beaconsfield, saw him with Dr. Quain alone. And it was feared that if Dr. Kidd was *not present* at this second visit with Dr. Quain and Dr. Bruce, Lord Beaconsfield would be much disturbed. Under these circumstances Sir William Jenner, in the interest of the patient, consented to see the noble lord in Dr. Kidd's presence. After the examination, Sir William Jenner expressed his views to Dr. Quain, Dr. Kidd being still present, but in no sense of the word did Sir William Jenner consult with Dr. Kidd. In brief, Sir William Jenner did all that the condition of his patient required while avoiding any breach of professional etiquette.

As we pointed out at the commencement of this illness, the noble lord's strength has long been a matter of *mental* energy; it has therefore been especially necessary that he should be sustained by *mental* stimuli. His was not the case of a man suffering from worry, or what is erroneously called "overwork." At no period of his brilliant career has this great statesman suffered from disorderly work. His mind has been too well-balanced, and his method too consistently clear-headed to leave him exposed to the perils which beset less calmly earnest workers. To deprive such a man of his normal sources of energy was to enfeeble his very powers of life. We are in no way surprised to hear that the appearance of Lord Rowton at the bedside of the noble earl, and the personal influence of his nearest friend of many years past, acted as a restorative, and enabled Lord Beaconsfield to "rally." The only marvel is that this obvious method of reviving the failing strength was not more promptly applied. Lord Beaconsfield has had an attack of undeveloped gout with the characteristic bronchitis. The so-called "spasm" has been the result of the accumulation of viscid secretions in the bronchial tubes, the accumulation being indicated by the usual physiological consequences of a deprivation of oxygen, together with special nervous depression. Spasm of the muscular coats of the air-passages is common in gout, and in the case of Lord Beaconsfield the constitutional peculiarity has rendered the spasm worse. The unavoidable but most untoward absence of Lord Rowton during the early period of the illness exercised a depressing effect, and rendered the treatment more than ordinarily difficult. The medical question of the moment is whether proper means can be taken to relieve the bronchial tubes and so avert the spasm when it occurs; the noble lord can be supplied with suitable nourishment at very short intervals, so as to keep up his strength. For the rest, the issue is simply a question of vitality, and that, as we have insisted, it depends almost exclusively on the mental strength in reserve, and the mental treatment to which his lordship may be subjected.

URÆMIA.

THE inoffensiveness of urea when injected into the blood, a fact of much interest in connexion with current theories of certain symptoms in renal disease, asserted by many experimenters, has been confirmed by MM. Richet and Martin in some experiments described to the Académie des Sciences. Even fifty grammes, nearly an ounce and three-quarters, did not cause the immediate death of a dog of medium size. The investigators then endeavoured to ascertain the percentage of urea in the blood half an hour after the injection of a considerable quantity, and they conclude from the results which they obtained that not more than one-eighth part of the amount injected can then be found in the blood. It is remarkable that the same result was obtained even when both kidneys were ligatured. It must hence be assumed that the urea injected passes at once into the tissues and liquids of the organism, and, in accordance with this supposition, a notable elimination was found to occur by means of the stomach and intestine. The contents of the stomach yielded at the rate of fifteen grammes of urea per litre, and the saliva five grammes per litre. Doubtless a similar passage of urea occurs into the lymph, the muscles, and the parenchyma of the tissues. Urea injected into the blood is only very slowly eliminated by the kidneys. A very remarkable fact, and one most difficult to explain, is that although urea acts as a diuretic, causing a considerable total increase in the quantity of the urine, it lessens the percentage of urea contained in it. There is an elimination of water out of all proportion to that of urea. Nevertheless, animals whose kidneys have been tied die far more quickly after an injection into the blood of a moderate quantity of urea (20 grammes) than if no such injection is made. They die in sixteen, eighteen, or twenty hours, whereas, after simple nephrotomy, they usually live for forty-eight hours. The injection into the blood of a small quantity of chloride of ammonium has the same effect. The injection of moderate doses of neutral salts of ammonia beneath the skin does not occasion any considerable toxic effects, far less than if they are injected into the blood. This fact makes it difficult to attribute the symptoms known as uræmic to the non-elimination of the salts of ammonia. The mucous membrane of the stomach of animals dying after the injection of urea into the blood is strongly ammoniacal. A small quantity of such mucous membrane, placed in contact with a solution of pure urea, causes it to decompose with great rapidity, just as if a soluble or organised ferment had been added, a very suggestive fact on which the authors promise a further communication.

THE MEDICAL REFORM QUESTION IN YORKSHIRE.

A MEETING held at Leeds on the 6th inst., to consider the subject of medical reform, was numerously attended, almost every large town in Yorkshire being represented by one or more members of the profession. The feeling of the meeting was clearly indicated by the marked expression of approval which followed Dr. Allbutt's trenchant remarks regarding the hopelessness of any real improvement in the existing system of medical education under the auspices of the General Medical Council as at present constituted. The sense of the meeting was also expressed with tolerable precision as to the necessity of reducing the number of members of Council, and that a large proportion of its members should be elected by the votes of the profession. It does not follow that the gentlemen thus elected should neeessarily be general practitioners. It was felt that the profession at large could well be trusted to judge as to the men who were best calculated to advance the interests of medical education and the well-being of the profession, and that they would vote for candidates for the Council irrespective of any considerations as to which branch of the profession such candidate might belong. In placing the subject of the reconstruction of the Medical Council first on the list of the resolutions and in the hands of one of the most distinguished physicians in the North of England, the meeting at Leeds plainly indicated their opinion of the importance they attached to this measure, and their belief that a change in this direction is necessary before any reasonable hope can be entertained for the improvement of medical education in this country. The subject next in importance to the emancipation of the General Medical Council from the baneful influence that is exercised upon it by the corporations is the desirability of creating conjoint and complete examinations for each division of the kingdom. As Mr. Wheelhouse remarked, no legislation on this subject can be satisfactory which does not provide for such examinations. Mr. Wheelhouse reiterated the arguments we have frequently made use of, and the Leeds meeting unanimously supported him in his observations as to the desirability of reducing the number of the doors through which men are now able to enter the profession. There can be no question that it is absolutely to the disadvantage of the profession that students should be able to seek entrance into its ranks first at one door, and then, if they failed, at another, and so on till they gained their end. A few only of these nineteen bodies give anything that can be called a complete examination. At the present moment a man by passing in Anatomy and Surgery alone can place his name upon the Register, and claim to be a practitioner. Mr. Wheelhouse remarked some people imagine that some joint boards of examiners, such as he had referred to, would be the means of reducing all our students to one dead level, and tend rather to lower than increase the average standard of their professional attainments; he believed these premisses were unfounded, and that the majority of our students would not be contented with the minimum standard, or pass examinations, but would strive to obtain the diplomas and fellowships of our various colleges. We sincerely hope, with Dr. N. de Bartolome, that the meeting at Leeds will be followed by similar gatherings of the profession in other large towns, so that the action commenced at Leeds may proceed until the profession have impressed upon the Government the fact that by far the majority of medical practitioners in this country not only know what they want, and the nature of the measures they refer to when they talk about medical reform, but that they are earnest in the matter, and determined to attain their end in spite of every obstacle. The result of the Leeds meeting was summed up in a petition to Parliament, which has been already numerously signed by the medical practitioners of Yorkshire. The most gratifying feature about this meeting in Leeds is the evidence it affords that medical reform is a question, above all things, of a more efficient Medical Council and more complete and fewer examining bodies.

CINCHONA CULTIVATION IN JAMAICA.

WE lately referred to the promising extension of the cinchona cultivation in the island of Jamaica, and some further details of interest are contained in the "Annual Report of the Public Gardens and Plantations in Jamaica," for the year ending the 30th September, 1880, by Mr. D. Morris, M.A., F.G.S., Director. The work has been retarded by severe hurricanes and storms which have inflicted great damage on plantations, but, nevertheless, the progress has been very satisfactory. About 50,000 cinchona plants have been set out in their permanent places, of which 43,000 were C. officinalis, 6000 were C. calisaya, and 1000 C. succirubra. No new land has been opened up, these plants having been used in planting the remainder of the land cleared and partly planted in preceding years. A striking proof of the suitability of the soil for the cultivation of the tree is afforded by the fact that in two plantations the original planting has been completely masked by the abundant growth of self-sown seedlings, some of which are now large enough to be cropped, and there is the promise of a succession of valuable crops for several years. Root bark from these seedling trees has realised 10*s.* per pound, and trunk bark 8*s.* per pound. Moreover, these self-sown seedlings were to the number of 100,000 transplanted to nurseries, where about 350,000 others were raised from seed. Several new species of cinchona have been introduced, especially a valuable variety of Columbian bark and the true Calisaya bark; it having been found that the plant cultivated in the island as such was really a hybrid, partaking more or less of the red bark character, and, although a valuable form, is less so than the true yellow bark. Several cuttings have also been introduced from Kew of the precious Ledgeriana variety and are thriving. This variety has been called by Mr. Howard "The Prince of Cinchonas." Quite recently bark of this form has been sold in the London market at 14*s.* 8*d.* per pound, and that from trees grown in Java has been sold in Amsterdam at 17*s.* per pound. The aggregate amount of bark shipped to England during the year was 27,299 pounds, which sold for £5380, and was yielded by 8248 trees. The evidence afforded by the rapid growth of self-sown seedlings that the climate of the Blue Mountains is specially suitable for the growth of cinchona is corroborated by another very interesting fact mentioned in the report. Twelve years ago a few seedlings were planted for experiment on one or two estates, and most of the plants were removed when the regular nurseries were opened. Hearing last year that a few cinchonas had been left at one of these experimental plantations at an elevation of 4800 feet, Mr. Morris determined to visit the spot and ascertain their condition. Nothing had been done to the land since 1868, and the road thither was almost impenetrable. The trees were found to occupy an area of 120 square yards, and to be no less than 379 in number, and some were only nine inches apart. Most were of the Crown bark (C. officinalis), and about twenty feet high, with clean tall stems, the largest measuring fifteen inches in circumference at the base. The condition of the trees showed clearly that when a cinchona plantation has been established and the trees completely cover the ground, say in the third year from planting, no further attention is necessary till they arrive at maturity. Mr. Morris examines the question of whether the extensive cultivation of cinchona is likely to render it an unremunerative object of industry, by lowering the price of quinine, but he concludes, with much show of reason that the death-roll among all the nations of the world from fevers, for which it is the sole remedy, is so vast that there is no prospect of the price of quinine being seriously diminished. On the contrary, the prices of good quinine-yielding barks have been rising. At any rate, the cultivation in Jamaica would seem to have nothing to fear, for it is estimated that the yield per acre from the crown barks, in suitable localities and properly planted, would not be less than £1980, while if Ledgerian bark is grown it would be £2000. It is evident that the quinine might fall considerably in price, and yet its cultivation under such conditions might yield a handsome profit.

APPOINTMENT OF A HOMŒOPATH AS MEDICAL OFFICER OF HEALTH AT HASTINGS AND ST. LEONARDS.

Surprises, like misfortunes, seldom come singly. Before we have been able to realise the fact that a London physician is in daily consultation with a reputed homœopath the news reaches us that a member of that persuasion has just been elected as Medical Officer of Health at one of our chief watering places and health resorts. The facts of the case are briefly as follows. Through the retirement of Mr. Ashenden a vacancy was recently created in the post of Medical Officer of Health for the Hastings Urban Sanitary District, and in response to an advertisement nine candidates came forward, some of whom, from their high qualifications and professional standing, were entitled to receive every mark of consideration and respect from the members of the Town Council. Nevertheless, at the monthly meeting of that body, without even appearing to consider the claims of the more eligible candidates, they at once proceeded to elect Mr. Knox Shaw, the youngest of the applicants, and who has recently commenced practice as a homœopath at St. Leonards. It is alleged that the municipal body have been actuated in the matter by political motives. If that be so, we are at a loss to conceive how a body of gentlemen, elected to watch over the interests of a flourishing town, can have subordinated those interests to any collateral considerations. That the welfare of Hastings and St. Leonards may be materially affected by this injudicious proceeding we have no doubt. In order that the functions of a medical officer of health shall be efficiently performed, it is of the utmost importance that this gentleman should possess the entire confidence of his professional brethren, and feel assured of their support in the discharge of his delicate and responsible duties. As matters at present stand at Hastings and St. Leonards it is impossible that the medical officer should receive confidence and support, for members of the profession cannot place themselves in unreserved communication with one whose views differ so materially from their own on every subject connected with medical practice. The sanitary condition of the town is, therefore, likely to suffer materially, and we need hardly say how any suspicion of that kind must be calculated to injure the prestige of the place with visitors and invalids. One of the first questions asked nowadays by patients, or even by persons merely seeking change of air, of their medical attendants, relates to the sanitary condition of the place they intend to visit. What information can medical men at a distance obtain with regard to those two towns when they are of necessity debarred by professional considerations from holding communication with the present sanitary officer? The medical men of the district have already discharged their duty by issuing a dignified protest. The fame of "Hastings and St. Leonards" as an invalid resort has been in part due to the high professional reputation of its medical men, and there can be no doubt that the two towns are greatly indebted to the members of our profession generally for much of their substantial prosperity.

It will be gratifying to his numerous English friends to learn that the health of Dr. J. Marion Sims has to a considerable extent been re-established. Dr. Sims has received a cordial welcome from his medical brethren at Charlestown, who propose to give him a public reception.

The Honorary Fellowship of the Royal College of Surgeons in Ireland was last Wednesday, the 13th inst., conferred on Professor Helmholtz, of Berlin; and the Honorary Degree of LL.D. by the University of Dublin.

We learn that the prize of £50 for the best essay "On the Treatment of the Opium Habit" has been awarded by the adjudicators, Sir Risdon Bennett, Sir J. Fayrer, and Dr. Sieveking, to Dr. George Shearer of Liverpool.

At an inquest held at Battersea on Tuesday on the body of a woman who died from exhaustion during parturition, a verdict of "manslaughter" was returned against the unqualified assistant at a dispensary, who was called to the case.

We regret to learn that Dr. Frederick Hulke, the well known and esteemed practitioner in Deal, died suddenly on Sunday last.

We may remind our readers that there will be a meeting of the Pathological Society on Tuesday next, the 19th.

The Brighton Town Council has decided to erect a sanatorium at a cost of £15,000.

Ambulance Practice by Volunteers. — A number of the officers, non-commissioned officers, and gunners of the 7th (Manchester) Lancashire Artillery Volunteers have during the past two months attended a course of practice prescribed by the St. John Ambulance Association, the instructor being Dr. Tomkins, honorary surgeon of the corps. On April 4th, Surgeon-Major Hutton, of the Rifle Brigade, conducted an examination of the men in ambulance practice at the Artillery Barracks, Hyde-road. They acquitted themselves in an efficient manner.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORT OF MEDICAL INSPECTOR OF THE LOCAL GOVERNMENT BOARD.

Enteric Fever at Newlyn, East (Dr. BALLARD).—Newlyn (East) is a decayed mining village in the rural sanitary district of St. Columb, Cornwall. It contains about 150 houses, nearly all of the cottage class, and about 650 inhabitants. Much of the village is in a grievously dilapidated condition, some of the occupied houses unfit for habitation, and indications of gross sanitary negligence are apparent everywhere, even to overcrowding of the dead in the churchyard. Several times this village has been scourged by enteric fever, and in October last another outbreak began, which in the course of the next three months attacked 67 families, giving rise to 116 cases, and killing 14 or 15. The attention of the Local Government Board was called to this formidable outbreak by a notice of it in the London daily press, no information of it having been given to them by the medical officer of health, as in duty bound, he having been forbidden to do so by the Rural Sanitary Authority. Dr. Ballard was directed to make inquiry by the Local Government Board into the accuracy of the reports which appeared in the public press, and having ascertained this, if requisite, to investigate the circumstances of the outbreak of disease and give such help to the sanitary authority in dealing with it as might prove to be necessary. The origin of the largely diffused outbreak was readily traced to the excremental pollution of two of the principal sources of water-supply of the village—the one a well with which a common sewer communicated, and with which the sewer must have been in free communication shortly before the outbreak, the other a spring outside the village, and situated in a hollow. The surroundings of this spring were found to be such as "to inspire simple disgust, since the surface of the field and the ditch close to the spring were defiled with human excrement deposited there by the women and children when they came to fetch water. They probably had no privy at home." The general insanitary state of the village, particularly as to excremental nuisances, contributed to keep up and extend the outbreak when the disease had once declared itself.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Burgh of Hillhead (*Glasgow*).—Dr. James Christie reports for 1880 a birth-rate of 24·00 and a death-rate of 9·43 per 1000 among a population numbering 7000. The average mortality of the burgh of Hillhead during the last three years, it appears, was only 11·0 per 1000 living, "a death-rate much lower than that of the insular rural districts of Scotland, which invariably show the lowest death-rate in the country." This remarkably low death-rate, according to Dr. Christie, "depends to a large extent on careful modes of living, and on the fact that the houses are commodious and not overcrowded, and that all cases of illness, as a rule, receive early attention," but, he adds, "it must be conceded that it is, in some measure at least, due to healthiness of site, proximity to the open country, and to attention on the part of the Local Authority to matters affecting the public health of the district."

Dublin: February, 1881.—Dr. Cameron reports for this month a death-rate of 44·25 per 1000 inhabitants, the rate on the northern side of the city being 46·45, and on the southern side 42·52. The deaths from zymotic diseases were considerably under the average for the month of February during the last ten years. On the high mortality of the month he observes that it "cannot be ascribed to the prevalence of zymotic disease, for the proportion of deaths from this class of maladies to the total deaths is much below the average of former Februarys, and of very many towns. A very high proportion of the mortality was due to diseases of the respiratory organs, especially of bronchitis and pneumonia. The want of proper food, of warm clothing, and of comfortable dwellings, are prime factors in causing diseases of the breathing organs. For some time past these factors, the result of poverty, have done their deadly work amongst the humbler classes of Dublin. The workhouses are crowded, there are large numbers of persons out of employment, and the unusual severity of the winter has sown the seeds of many such diseases as chronic bronchitis, phthisis, and rheumatism."

Dorchester (*Urban*).—Mr. E. J. Day reports for this urban district for 1880 a birth-rate of 32·4 per 1000 inhabitants, and a death-rate of 18·8, the population being estimated at 7435. A good deal of sanitary work, according to Mr. Day's report, appears to have been done during the year, and a scheme for the drainage of the town is occupying the attention of the sanitary authority.

Dorchester, Rural (*Eastern Division*).—Mr. E. J. Day's report for 1880 for this division shows a birth-rate of 24·8 per 1000 inhabitants, and a death-rate of 17·2, the population being estimated at 5352. Here also more or less detailed sanitary work has been done, but we notice among the items of work mentioned the doubtful proceeding of the construction of a cesspool of circular shape, thirty feet in depth and six feet in diameter, "*adjoining* the south wall of the workhouse." The italics are ours.

Dorchester, Rural (*Maiden Newton*).—Mr. Wm. Rendall, the medical officer of health for this division of the rural sanitary district, reports for 1880 a birth-rate of 23·74 per 1000 inhabitants, and a death-rate of 18·47, among a population estimated at 6640. He has the following observations on farmyard and pig nuisances:—"Complaints have frequently been made to me of the nuisance arising from farmyards, dairy-yards, and pigstyes situated in the centre of villages close to dwellings and public roads. This is undoubtedly the case, and as long as these yards are so situated animals must be kept there and the nuisance will arise; of all animals pigs seem to be the most objectionable, and generally give rise to the complaints made. Again, I believe these yards are often the means of polluting wells for some distance round; several cases have come under my notice where well water is discoloured and unfit to drink after a storm, and I have invariably found these wells situated near a yard. The yards are usually hollowed out and filled with manure, and after a storm of rain are overflowing with liquid manure, which gradually percolates the soil and pollutes the springs which run in that direction. The consequence is that all wells supplied by these springs are polluted." It is worthy of note that at Maiden Newton privies, with few exceptions, have been converted into earth-closets, and are satisfactorily managed by the inhabitants themselves.

THE OKEHAMPTON WORKHOUSE.

A report has been presented to the Okehampton Rural Sanitary Authority on the sanitary condition of the workhouse of the Union, by Mr. Linnington Ash, their medical officer of health. The report is an excellent illustration of the advantages to be derived from the employment of medical officers of health in the sanitary inspection of these buildings. The workhouse is not a very old one, but it was built at a time before that clear knowledge of the sanitary requirements of buildings of this class, which we now possess, was obtained, and, in consequence, it has very numerous defects in its arrangements for ventilation, sewerage, water supply, dormitories, sick accommodation, offices, and general convenience, which it is not desirable should remain for one moment longer than necessary for removal after their discovery. How many of these defects have remained so long unremedied, or rather, we should say, undiscovered, is one of those mysteries of official poor-law inspection we do not pretend to explain, but which shows that the ordinary inspection of the Local Government Board in sanitary matters needs as much as ever to be supplemented by inspection such as this of which Mr. Linnington Ash has given us a specimen. Mr. Ash describes the general plan of the Okehampton workhouse as good, and lending itself readily to such changes in internal arrangements as is to be desired, although the site is not well chosen.

SANITARY HOSPITAL ACCOMMODATION.

It is an old saying that "we may take a horse to the water, but we cannot compel him to drink"; and it would appear from our contemporary, the *Local Government Chronicle*, that we may induce a sanitary authority to build a hospital, and give the gratification to the ratepayers of paying the cost of it, but the sanitary authority is not bound to keep it open for the reception of patients.

The *Local Government Chronicle* reports a curious case of river pollution from Salford. A bargee engaged in the removal of town refuse from the Corporation manure wharf on the canal for carriage into the country, hit upon the ingenious idea of saving his time and labour by depositing his cargo, consisting of no less than twenty-three tons of filth of one sort and another, in the river with which the canal communicates!

Dr. Tatham, the medical officer of health for the borough of Salford, has recently been delivering in that borough a popular lecture on the "Nature and Prevention of Infection."

The City of London Union and the Kensington Guardians appear to have protested against the further expenditure of money by the Metropolitan Asylums Board in legal proceedings regarding the Hampstead Hospital.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

English urban mortality showed a further slight increase last week upon that which had prevailed in recent weeks. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 5277 births and 3264 deaths were registered last week. The births exceeded by 91, and the deaths by 7, the average weekly numbers during 1880. The deaths showed a further increase of 68 upon the low numbers returned in recent weeks. The annual rate of mortality in the twenty towns, which had been equal to 20·6, 21·7, and 21·9 in the three preceding weeks, further rose to 22·4 last week. The lowest rates in these towns were 16·0 in Portsmouth, 17·9 in Leicester, 18·7 in Brighton, and 19·0 in Bristol. The rates in the other towns ranged upwards to 26·1 in Manchester, 26·2 in Oldham, 27·8 in Wolverhampton, and 28·0 in Liverpool. During the thirteen weeks ending the 2nd inst., the death-rate in the twenty towns averaged only 23·9 per 1000, against 25·7, the average rate in the corresponding periods of the five years 1876–80.

The deaths referred to the principal zymotic diseases in the twenty towns, which had been 321 and 315 in the two preceding weeks, rose to 339 last week; these included 78 from measles, 73 from small-pox, 71 from whooping-cough, 45 from scarlet fever, and only 26 from fever, principally enteric. The annual death-rate from these principal zymotic diseases averaged 2·3 per 1000 in the twenty towns, and ranged from 0·0 and 0·4 in Brighton and Leicester, to 3·4 both in Portsmouth and Wolverhampton. Whooping-cough showed the largest proportional fatality in Portsmouth and Leeds, and scarlet fever in Wolverhampton. The 16 deaths referred to diphtheria in the twenty towns included 11 in London and 2 in Portsmouth. The highest death-rates from fever, mainly enteric, were recorded in Newcastle-upon-Tyne and Portsmouth. Small-pox caused 77 more deaths in London and its outer ring of suburban districts, and one in Liverpool, but not one in any of the eighteen other provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 820 and 899 at the end of each of the two preceding weeks, further rose to 921 on Saturday last, exceeding the number under treatment at these hospitals at any time since May, 1877. The number of new cases of small-pox admitted to these hospitals during last week was 224, against 147 and 256 in the two preceding weeks.

The deaths referred to diseases of the respiratory organs in London, which had been 348 and 358 in the two preceding weeks, were 359 last week, and no less than 91 below the corrected average number in the corresponding week of the last ten years; they included 221 from bronchitis and 94 from pneumonia. The annual death-rate from lung diseases, exclusive of phthisis, was equal to 5·0 per 1000 in London last week; the rate from the same diseases was no less than 9·0 in Liverpool, but did not exceed 4·3 in Salford.

The causes of 90, or 2·8 per cent., of the deaths in the twenty towns last week were not certified, either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths was equal to 2·4 per cent. in London, and averaged 3·1 per cent. in the nineteen provincial towns. No uncertified deaths were recorded last week in Brighton, Portsmouth, Norwich, Bristol, or Leicester; while the proportions of such deaths were largest in Salford, Hull, Leeds, and Sheffield.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week was equal to 23·5 per 1000, against 23·5 and 20·7 in the two preceding weeks; this rate exceeded by 1·1 the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 17·6 and 19·1 in Dundee and Leith, to 27·3 and 33·9 in Perth and Paisley. The deaths referred to the principal zymotic diseases in the eight towns, which had been 97, 75, and 69 in the three preceding weeks, rose again to 82 last week; they included 26 from whooping-cough, 20 from diarrhœa, 11 from fever, 12 from diphtheria, 7 from measles, 6 from scarlet fever, and not one from small-pox. The annual death-rate from these zymotic diseases averaged 3·2 per 1000 in the eight towns, which was 0·9 above the mean rate from the same diseases in the twenty English towns. This zymotic death-rate in the eight Scotch towns ranged from 1·3 and 1·7 in Greenock and Leith, to 3·9 and 4·4 in Perth and Aberdeen. The fatal cases of whooping-cough, which had been 31, 27, and 16 in the three preceding weeks, rose again last week to 26, of which 13 occurred in Glasgow, 6 in Edinburgh, and 3 in Aberdeen. The 20 deaths from diarrhœa showed a further increase upon recent weekly numbers, and exceeded the average number for the season; they included 7 in Glasgow, 4 in Dundee, and 3 in Aberdeen. The 12 deaths referred to diphtheria corresponded with the number in the previous week; 8 were returned in Glasgow and 2 in Paisley. The 11 deaths referred to "fever" showed an increase, and included 7 in Glasgow and 2 in Edinburgh; the death-rate from this cause in the eight towns was twice as high as the average rate in the twenty English towns during the week. Four of the deaths from measles occurred in Glasgow, and the other 3 in Aberdeen; the 6 from scarlet fever included 4 in Edinburgh and 2 in Glasgow. The deaths referred to acute diseases of the lungs in the eight towns, which had been 138 and 146 in the two preceding weeks, further rose to 163 last week, and were equal to an annual rate of 6·5 per 1000, while the rate from the same diseases in London did not exceed 4·2; these diseases were especially fatal in Glasgow.

HEALTH OF DUBLIN.

The excessive rate of mortality in Dublin showed no decline last week. The annual death-rate in the city, which had been equal to 34·9 and 30·8 per 1000 in the two previous weeks, was again 30·8 last week. During the thirteen weeks ending on the 2nd instant, the death-rate in the city averaged no less than 37·8, against 23·4 in London and 22·3 in Edinburgh. The 197 deaths in Dublin last week corresponded with the number in the previous week, and included 14, or rather more than 7 per cent., which were referred to the principal zymotic diseases, against 19 and 15 in the two previous weeks. The 14 deaths from zymotic diseases included 8 from fever (typhus, enteric or typhoid, and simple continued), 4 from diarrhœa, 1 from scarlet fever, 1 from whooping-cough, and not one either from small-pox, measles, or diphtheria. The annual death-rate from these zymotic diseases did not exceed 2·2 per 1000 in Dublin last week; it was 3·0 in London and 3·1 in Edinburgh. The deaths referred to fever in Dublin, which had been 12 and 7 in the two previous weeks, were 8 last week; and the annual death-rate from this cause was seven times as high in Dublin as the average rate in the twenty English towns. The fatal cases of diarrhœa exceeded the number returned in recent weeks; while the deaths referred to other zymotic diseases were exceptionally few. The deaths of infants showed an increase upon those returned in the previous week; while those of elderly persons were fewer than in either of the two preceding weeks.

VITAL STATISTICS OF THE PUNJAB.

We are in the receipt of weekly returns of vital statistics for the Punjab Province of India, bearing the signature of Surgeon-Major Bellew, Sanitary Commissioner, which reflect great credit upon the local sanitary administration. These returns appear to be uniformly furnished for the entire province, which was reported to have had a population at the last census in 1875 of about seventeen and a half millions of persons. During the two weeks ending 5th and 12th Feb.

last the annual death-rate among this population was equal to 27·6 and 28·8 per 1000 respectively. It appears that only three deaths from cholera occurred in the province during the fortnight, and that the fatal cases of small-pox in the two weeks were 184 and 193 respectively. The most remarkable feature of the return is the fatality from fever; of 18,994 reported deaths in the province during the fortnight, no less than 12,566, or more than 65 per cent., were attributed to fevers. If these deaths from fevers be deducted from the deaths from all causes the annual death-rate from other causes in the fortnight would not exceed 9·5 per 1000, affording strong presumptive evidence that the term "fevers" must have a somewhat indefinite and wholesale signification in the returns. These weekly returns include detailed vital statistics for each of fifty-two large municipal towns, having an aggregate population of about a million and a quarter persons, among whom the average birth-rate in the fortnight was 39·0, and the death-rate 31·5 per 1000. Bearing in mind that in the capitals of the three presidencies registration of births has hitherto been a comparative failure, it is somewhat surprising to find in the returns before us apparently trustworthy returns of births in the fifty-two principal towns of the Punjab. Taking the two returns before us as indicative of the sanitary condition of these Punjab towns, we find, as might be expected, very excessive mortality in many of them. The largest town in the list is Amritsar, with a population of 136,166, which had a death-rate of 37; in Delhi, having a population of 115,992, the rate was 40. The third largest town in the list is Peshawur, the population of which is given as 58,430; the mean mortality of this town in the fortnight was 48, fever fatality showing a terribly high proportion of the total mortality. Assuming that the birth returns are approximately trustworthy, we may venture to suggest to the Sanitary Commissioner that an additional column to his excellent return, showing the deaths under one year of age, would afford valuable information on a most important and interesting subject—infant mortality in India.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

SANITATION AT CANNES.

The town of Cannes is about to contract a loan for £120,000, of which a third is to be employed to pay off the local floating debt. The rest will be devoted to public works, and we must commend the appropriation of this money as being dictated by sound sense. Fortunately the present administration of Cannes has at last realised that the preservation of public health is the first duty of a health resort. Hence it has been resolved to construct, and this at a cost of about £14,000, proper sewers in no less than nineteen streets. The present abominable sewers will be replaced by new egg-shaped conduits. If these latter are properly ventilated, an end will be put to the bad odours for which the streets of Cannes are too notorious. There are also four rivulets which at times assume the proportions of mountain torrents, and are invariably more or less contaminated by the refuse of neighbouring houses. To prevent the formation of stagnant pools and the decomposition of organic matter on the banks during dry weather, the bed of these rivulets will be converted with cement and masonry into a smooth channel, down the centre of which the smallest volume of water will pass on easily to the sea. The greatest work, however, will be the destruction of the most unwholesome district of the town called the Poussiat. Eighty-five houses must be pulled down, and a market and two broad streets built on the site. The cost of compensating the various proprietors in this and other districts, where narrow unhealthy streets are to be widened, is estimated at £40,000. In all, out of some £80,000 to be spent, only about £2000 will be employed for embellishments totally unconnected with the improvement of public health, and £3000 for the building of a school. This is a great and favourable contrast to, for instance, the town of Hyères, where a loan was contracted last year for £60,000, and only £880 devoted to the repairing of water conduits and canals. The example given by the town of Cannes is therefore all the more worthy of notice. At present, Monaco, Monte Carlo, and even the intervening low-lying quarter of the Condamine, is the only well drained district of the Riviera. Though the house drainage in the Principality is still very imperfect, the streets, at least, are marvellously well kept, even in the poorest localities, and are completely free from the noxious effluvium which is the bane of these southern winter stations. The Republican administration of Cannes have now determined, however, to keep pace with the monarchical government of Monaco, though their financial resources are not so large and their executive powers are strictly limited.

BERI-BERI.

Two important recent additions have been made to the literature of beri-beri; the first from the pen of Dr. T. Irvine Russell, Principal Civil Medical Officer of the Straits Settlements, in the form of a report on the prevalence of the disease in the criminal prison, Singapore; the second by Dr. Duane B. Simmons, Director of the Government Hospital, and President of the Foreign Health Board, Yokohama, in an elaborate paper published in the Medical Reports issued by the Chinese Customs (Special Series, No. 2). Dr. Irvine Russell's report gives a very careful and instructive account of *beri-beri* as it has been observed in the criminal prison of Singapore from May, 1875. From that date to the end of May, 1880, 1174 cases (of which 165 died) had been observed in the prison under circumstances very favourable for observing the disease. According to Dr. Russell, damp and malaria are the chief conditions provocative of *beri-beri*, malaria being essential. Dr. Simmons' paper is illustrated by a map and several instructive outline illustrations of patients in different phases of the disease. He regards *beri-beri* as arising from "a specific miasm or ground exhalation." Our contemporary the *Indian Medical Gazette* in its last received number gives, in a note from Dr. W. Carey, a curious extract from an account of life in Bombay two or three centuries ago, or thereabouts, in which the phrase *berri-berri* appears. "After drinking toddy rapidly," reads one sentence, "they took a disease called *barbieri* or *berri-berri*, in which a man tottered in his gait like a dying sheep, or span round like a teetotum." Dr. Carey asks, "Has the disease mentioned any connexion with *beri-beri* which excited discussion lately?"

An action (Hicks *v.* Doubledee) has been recently tried before Vice-Chancellor Hall to set aside an agreement to take a lease of a house in Sussex, which had been advertised in our pages in September last as suitable for a sanatorium or convalescent hospital. Tempted by this advertisement, the plaintiff, a medical men, entered into communication with the defendant, which ended in his signing an agreement to take the house on lease. After he had entered upon the occupation of the premises, the plaintiff found—contrary to what he had been led to believe, as he asserts, by the defendant—that the chimneys smoked intolerably, the water-supply was impure, and the drainage arrangements very defective; and he sought to free himself from the agreement. The case occupied nearly a fortnight in the trial, and the evidence tendered was of the most contradictory character. In the end the Vice-Chancellor decided that the plaintiff had entirely failed to make out his case, and dismissed the action, with costs, giving judgment in favour of the defendant.

The growing custom of members of Parliament asking questions in the House of Commons on general medico-sanitary matters deserves notice. It is evidently found much more convenient to ask a minister than to take the trouble of referring to a work in the library. But is it well that ministers should yield so readily to this habit, wasting the time of the House, and encouraging the laziness of certain of its members? Is a member of Parliament by virtue of his position released from the necessity of acquiring knowledge as other people have to acquire it?

The owners of several houses in the vicinity of Stanhope-street, Euston-road, were summoned at Marylebone Police Court for allowing their premises to lapse into an unhealthy condition. The insanitary state of the dwellings having been testified to by Mr. Shirley Murphy, the district medical officer of health, each of the defendants was ordered to complete the necessary work within seven days and to pay the costs of the summons.

Messrs. H. K. Lewis have issued a new edition (the tenth thousand) of Dr. Edward T. Wilson's most handy and useful card "Disinfectants, and How to Use Them."

THE SERVICES.

INSPECTION OF THE ARMY HOSPITAL CORPS.

The class of medical officers and men of the Army Hospital Corps who have just completed a course of training in "stretcher and ambulance drill" at Aldershot, was inspected on Monday last by Surgeon-General A. Shelton, Head of the Medical Branch War Office, in the unavoidable absence of Sir William Muir, K.C.B., Director-General. The class, which consisted of twenty-two medical officers and a large number of men, was drawn up on the parade ground in Z Lines, South Camp, under the command of Surgeon-Major Sandford Moore, and after an inspection of the ranks and a march past was put through stretcher drill by the Instructor, Surgeon Henry Bradford. Not the least interesting part of the day's proceedings was the presentation of the Zulu War Medal to twenty-four men of the Army Hospital Corps who had served in the late campaign, and to whom the Surgeon-General expressed his pleasure and gratification at conferring on them the decoration granted by Her Majesty for their services. After the inspection the Surgeon-General and his staff were entertained at luncheon by Surgeon-General Fasson and the officers of the Army Medical Department in their mess-hut in the South Camp.

THE ARMY HOSPITAL NATIVE CORPS FOR INDIA.

The Indian Government has sanctioned the formation of a Native Army Hospital Corps for service with British troops in that country. The head-quarters are established at the office of the Surgeon-General of Her Majesty's Forces, who is charged with the command of the corps and its general administration. All men joining the corps will be duly enlisted, attested as "hospital attendants," and will be subject to military discipline. Men belonging to the present existing hospital establishments will be eligible for enrolment, provided their age and character qualify them for admission; recruits will be enlisted as required. The corps will consist of the following classes—viz., ward servants, cooks, water-carriers or bheesties and sweepers. The total strength of the corps for the present is to consist of 1872. The scale of pay and pensions has not yet been promulgated, but it is understood it will be sufficiently liberal to attract a good class of servants, a want hitherto much felt in hospital administration in India.

THE BEARER COMPANY IN SOUTH AFRICA.

The Bearer Company of the Army Hospital Corps, under the command of Surgeon-Major William Johnston, arrived at Fort Napier, Natal, on the 28th of February from Durban, and, after some difficulty in getting its transport and equipment, proceeded to the front on the 5th March. The ambulances, waggons, stretchers, litters, cacolets, &c., were brought out from England with the Company, the transport consisting of 20 horses, 64 mules, and 120 oxen being obtained in the colony. The *Natal Witness* states that the conduct of the men since their arrival in Pietermaritzburgh has been excellent. Surgeon Connolly acts as adjutant of the Company.

The following medical officers, who have completed a tour of foreign service in India, will return to England during the present trooping season: Surgeon-Majors S. B. Roe, G. C. Gibbon, T. H. White, O. Owen, and G. J. Gibson. Surgeon-Major Roe accompanied the 92nd Highlanders to Natal for the Transvaal expedition from India.

Surgeon-Major E. Hopkins, Surgeons W. R. G. Hinds and W. Donovan, Army Medical Department, have embarked with the 85th Regiment from India for service in the Transvaal.

Surgeons J. G. Clery and J. Stevenson accompanied the 102nd Madras Fusiliers from Ceylon to Natal.

ARMY MEDICAL DEPARTMENT.—Surgeon-Major John Wales has been granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon-Major Francis Patrick Staples, from half-pay, to be Surgeon-Major; Surgeon-Major Charles Frederick Richards, M.B., has retired upon temporary half-pay.

INDIAN MEDICAL SERVICE.—The following appointments as Surgeons have been approved by Her Majesty:—Bengal: George Michael James Giles, Arthur Robert Wyatt Sedgefield, Edwin Francis Horatio Dobson, Johnston Shearer, Syed Hassan, Robert James Polden, Hem Chandra Banerji, Sambhu Chandra Nandi, Alfred Henry Pierson, Francis Samuel Peck, William Deane, and Philip de Conceiçao.—Madras: John Lawrence Vangeyzel, Hastings Norman Victor Harington, Gerard Macklin Eccles McKee, Kavasji Cursetji Sanjana, Hormasji Merwanji Hakim, John Adolphus Burton, Francis Joseph Doyle, Manekshaw Jamshedji Keláwálá, Philip Henry William Boon, Mervanji Pestanji Kharegat.—Bombay: Alexander Frederick Ferguson, Kavasji Hormasji Mistri, George Ernest Fooks, Joseph William Townsend Anderson.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of 1st April, 1881, the undermentioned Fleet Surgeons have been placed on the Retired List from the 1st inst., with permission to assume the rank and title of Deputy Inspector-General on the Retired List:—William Ross (b), M.D., James Lilburne, M.D., John Ruddall-Holman, M.D., William Patrick, Henry Loney, Robert Irvine, William Forrest MacClinton, B.A., M.B., Samuel Clift, John Chamberlayne Ingles, William Telfer, Marmaduke Philip Smyth Ward, Francis Yeates Toms, William James Hamilton, M.D.—The following appointments have been made:—Staff Surgeon William Redmond and Surgeon Joseph Crowley, M.D., to the *Repulse*.

ROYAL COLLEGE OF PHYSICIANS.

PERSONAL EXPLANATION BY DR. QUAIN; ELECTION OF PRESIDENT.

THE meeting of the Fellows of the College of Physicians on Monday last (the 11th inst.) was most numerously attended, nearly all the metropolitan Fellows being present, including Sir Thomas Watson, Sir James Alderson, and Sir George Burrows, who have in past times held the office of President. The occasion was a memorable one, the chief business being the election of a President for the ensuing year. Before this and the other business of the meeting took place, however, Dr. Bucknill, one of the censors of the College, rose, and begged to ask Dr. Quain to give an explanation of the reasons which influenced him in entering into consultation with a homœopathic practitioner.

The PRESIDENT (Sir Risdon Bennett) allowed the question to be put; but as it was a matter purely personal to Dr. Quain he ruled that no discussion could take place on it, as no formal notice had been given of the question.

Sir G. BURROWS asked whether such a question could be put until the business before the Comitia had been dealt with.

The PRESIDENT ruled that it might now be put.

Dr. QUAIN then rose and said that he was grateful for the opportunity afforded him of giving a personal explanation. He looked upon homœopathy as a creation of the imagination, which had no relations with scientific medicine. In the course of his long life he had never sought notoriety or publicity; and he felt sure that the Fellows, when they heard his explanation, would see that no other course was open to him. On the 29th of March Lord Barrington called on him and said that he had come to ask him to visit Lord Beaconsfield, that it was the wish of the Queen that further advice should be sought, and that Lord Beaconsfield had particularly requested to see him (Dr. Quain). He felt flattered by the request, but told Lord Barrington that he could not meet Dr. Kidd, who was a homœopathic practitioner. Lord Barrington said that he was not aware that Lord Beaconsfield was being treated homœopathically, and urged his request in strong terms. Dr. Quain, in reply, said that he must seek further advice, and did so. He went to a former President of the College, who told him that if the medical man were a qualified practitioner and were not treating the case homœopathically, Dr. Quain could not refuse to meet him. Acting upon this advice Dr. Quain next called upon Dr. Kidd, who told him and (at Dr. Quain's request) gave him a written statement to the effect that he practised medicine regularly, that he sometimes treated his patients homœopathically, but that he did not treat Lord Beaconsfield so. Dr. Quain then called on the President of the College and told him all the circumstances, and received the reply that he would not be justified in refusing the summons. The next day he saw Sir T. Watson and Sir James Paget, who both spoke in the same sense. He went to Lord Beaconsfield, and found that he was being treated actively, that Lord Beaconsfield had the utmost confidence in Dr. Kidd, so much so that the consequences to his lordship might have been serious were Dr. Kidd to withdraw from the case, and, under all these circumstances, Dr. Quain asked what other course could he have pursued? He had acted from the best motives.

Sir W. JENNER rose to make a statement, as he was personally involved in the matter.

The PRESIDENT said that no discussion could take place without formal notice of motion being given.

Sir W. JENNER said that he was not going to speak of Dr. Quain but only of himself. He, too, had been asked to meet Dr. Kidd, and had positively declined. "If, then," Sir William added, "Dr. Quain be right, it is I who deserve the censure of the College."

The ordinary business, which had been delayed by this episode, was then proceeded with. A communication from the General Medical Council relative to a preliminary scientific examination was read, and referred to the Council of the College for consideration.

On the motion of the PRESIDENT a grant of fifty guineas was made towards the expenses of the International Medical Congress.

The PRESIDENT then delivered the customary annual address. He said that during the past year eighteen members and seventy-eight licentiates had been admitted; that twelve new Fellows had been elected, the total number of Fellows being 304. Twelve Fellows had been removed by death. He referred to the manner in which the College had furthered the International Congress by devoting to the Executive the use of its rooms; and spoke of the alterations in the regulations for the Licence Examinations, which had already borne good fruit. The opposition of the College to the Vaccination Acts Amendment Bill had led to its withdrawal. The late Dr. Sparks had bequeathed his library to the College; pictures had been presented by Mr. Richmond, R.A., and Dr. Munro; and a legacy of £1000 had been bequeathed by Mrs. Bradshaw to the College (and also to the College of Surgeons) for the purpose of founding a lectureship in memory of her husband, Dr. Bradshaw, the lecture to be delivered on August 18th in each year, the day of Dr. Bradshaw's decease. In conclusion, Sir Risdon Bennett expressed his deep sense of the kindness and generous support he had received from the Fellows during his term of office. He had no fear for the future of the College, which was representative of British medicine, and he urged that the way to maintain its reputation was by circumspection in the elections into the Fellowship.

On the motion of Sir W. JENNER a cordial vote of thanks was passed to the President for his address with the request that it should be printed and sent to the journals.

The election of President was then taken by ballot. The result was that out of 108 Fellows present there voted—for Sir W. Jenner, 87; Sir R. Bennett, 7; Sir W. Gull, 5; Dr. Wilks, 2; Dr. Pitman, 2; Dr. Acland, 1; Dr. Quain, 1; Dr. Radcliffe, 1. Two papers were blank.

Sir W. Jenner, having obtained the votes of more than two-thirds of those present, was declared duly elected.

Sir THOMAS WATSON, as the Senior Fellow present, read the customary declaration, and handed the insignia of office to the new President, who then took the affirmation.

Sir W. JENNER, in thanking the Fellows for his election, said that the office of President of that College was the highest honour that could be conferred on any English physician. Its honour rested on that of the College, its dignity, the high scientific character and social status of its Fellows through all time. It had been enhanced by those who had filled the chair. The names of Watson, Alderson, Burrows, and Bennett were second to none in the profession; and they had discharged their duties with the greatest possible dignity. For himself, he felt unworthy of that post. Accidental circumstances, in the shaping of which he had no control, had placed him in the sunlight, and thus it had been that a large number of the Fellows had looked towards him; but he knew for that very reason that if he did anything which could be thought in the least way unworthy, he would not have been elected President. He felt, therefore, greatly honoured, for he knew they would not have selected him unless they felt confidence in him. He assured them he would keep to the solemn declaration he had taken, and added the satisfaction with which he had seen all the ex-Presidents present that day, and hoped that he had their support.

PHARMACOLOGY AND THERAPEUTICS.

THE INFLUENCE OF TEMPERATURE ON ABSORPTION.

M. SASSESKY has published in the *St. Petersburg Medical Wochenschrift* the results of some observations on the influence of temperature on the absorption of drugs. These were introduced by the mouth, the rectum, or by hypodermic injection, in the case of persons in good health, and of others suffering from various diseases. Iodide of potassium, salicylic acid, ferrocyanide of potassium, and hydrochlorate of quinine were given in solution, by the mouth and rectum, care being taken that each viscus was previously empty. The period after administration at which the drug could be detected in the urine was taken as the indication of the rapidity of absorption. For hypodermic injection solutions of iodide of potassium and of ferrocyanide of potassium were employed. It was uniformly found that, when given by the mouth or rectum, the higher the temperature of the solution the more rapidly was it eliminated, the difference varying from two to forty minutes, the results being somewhat influenced by the individual condition of the patients as well as by the differences in the temperature of the solution. In administration by hypodermic injection the results were less conclusive. In ten cases the warm solutions were absorbed the more quickly; in four, temperature made no difference in the rapidity of absorption, and in one case a cold solution of ferrocyanide of potassium was absorbed more quickly than a warm solution. Manassein has suggested that warm liquids produce a more intense hyperæmia of the mucous membrane, and hence are absorbed more quickly. It is possible also that cold liquids cause a more prolonged initial contraction of the vessels which will have the effect of delaying absorption.

RESORCIN.

Resorcin is a diatomic phenol extracted from certain plants, as assafœtida, and produced synthetically by the action of potash on chloro-phenyl sulphuric acid, to which we have before called attention (THE LANCET, 1880, vol. ii., p. 777). M. Dujardin-Beaumetz has lately corroborated its value as an antiseptic, and represents it as very serviceable in surgery. It causes poisonous symptoms in doses of more than six grammes. According to Andeer, sublimed resorcin has much less toxic properties. He asserts that it has not merely an antiseptic, but also a slightly caustic action upon mucous membranes, and does not give rise to a slough, the epithelium being regenerated in two or three days. He has employed it with advantage for the purpose of washing out the stomach in gastric catarrh and dilatation. It seems to possess certain hæmostatic actions, chiefly efficacious in capillary hæmorrhages. Soltmann has employed it in ninety-one cases of infantile "cholera," of which seventy-four were cured, and asserts that, putting aside three cases in which death occurred from grave complications, the use of the drug reduced the mortality from this disease in his practice from 34 to 15 per cent. It quickly arrests vomiting, even in small doses, and restrains the diarrhœa, without tending to cause the collapse or the toxic symptoms which result from the use of even small doses of carbolic acid. It is readily taken by children. The stomach and intestine rapidly regain their functional energy. He gave it to children under a year in a dose of ·1 to ·3 gramme in sixty grammes of infusion of chamomile.

THE ANTIPYRETIC ACTION OF IODINE.

Many observers have asserted that preparations of iodine possess the power of lowering the temperature in acute febrile diseases. A solution of iodine and iodide of potassium was recommended, for instance, by Hillebrand for this purpose in typhoid fever; and Coesfeld, in 1879, pointed out the antipyretic action of iodoform applied to the skin in febrile states. Binz, in a recent communication to the *Archiv für Exp. Pathologie und Pharmakologie*, attributes this effect to the liberation of free iodine in the system, and has demonstrated that iodic acid possesses the influence in a very high degree. In the artificial septic fever of rabbits he found the temperature could be reduced in an hour from 104° to 101½° by an injection beneath the skin of a grain and a half of iodate of soda dissolved in two cubic centimetres of water. Unfortunately the poisonous properties of iodic acid are an obstacle to its therapeutic use, and, when combined with an alkali, it cannot be given by the mouth, because free iodic acid is liberated in the stomach. Given hypodermically it is, however, effective, and seems to cause little local disturbance.

THE ANÆSTHETIC ACTION OF CHLORINE.

Ten years ago Cameron published a singular case of a sailor who died comatose after having slept in a cabin containing a quantity of chloride of lime. In the post-mortem it was noticed that a strong odour of chlorine was exhaled from the ventricles of the brain when they were opened, although the autopsy was only made thirty hours after death. Binz has recently observed a similar effect in the case of rabbits, and his researches show that chlorine, bromine, and iodine, when inhaled, paralyse the nerve centres, apparently by a direct action on the protoplasm of the nerve cells, and cause death by cessation of the respiration, not of the heart. It used to be taught that chlorine when inhaled is quickly transformed into chloride of sodium by combining with the alkali of the blood. It seems, however, that, as Cameron's case teaches, the chlorine may remain for a long time in contact with the lymph and blood without undergoing this transformation.

POISONING BY TANSY.

A case of fatal poisoning by this common English plant has occurred in America, and has been recorded in the *Pittsburg Medical Journal.* An infusion of about half an ounce of the dry herb was taken by a woman at bedtime. In a few hours the patient vomited and was purged, and then ceased, to recur in the afternoon with abdominal pain in the epigastric region, which became very severe; the breathing was rapid and shallow, and the pulse became very feeble. The patient died twenty-six hours after taking the tansy. Dr. Gallaher, who describes this case, also records another of poisoning, not from the infusion, but from the oil of tansy. It was taken in order to bring on menstruation, and, small doses having been ineffective, half a teaspoonful was taken at bedtime. Two hours later the patient was awakened by burning pain at the stomach and ringing in the ears; she became cold and pulseless; after an emetic, however, she rapidly recovered. In neither case was there any convulsion, coma, or paralysis.

DIALYSED IRON.

According to a writer in "New Remedies" the so-called dialysed iron of the United States is not prepared by dialysis, but is obtained by mixing a small proportion of hydrochloric acid with washed ferric hydrate precipitated by ammonia, and setting the mixture away for about three weeks, when the clear solution is decanted from a slight residue, and is then ready for use. The preparation is thus identical with that long in use in this country under the name of ferric oxychloride or chloroxide. The knowledge of the method by which it is prepared—that the American "dialysed iron" is not dialysed—is said to be kept so sedulously secret by the manufacturing fraternity that a practical chemist of some experience was laughed at for his simplicity when he proposed to make dialysed iron by dialysis. It is said that if the factories were restricted to dialysis for the product they could not possibly supply the demand—without, we suppose, increased labour, which would be more troublesome and expensive.

NITRITE OF SODA.

According to Binz and Barth the physiological action of the nitrites in general, and of nitrite of soda in particular, bears considerable resemblance to that of arsenic. Their high "reductibility" renders them powerful oxidising agents, and it is asserted that they are first reduced in the tissues of the greatest physiological activity, in the gastro-intestinal mucous membrane, and in the nerve tissues, and next in the blood, where the oxygen seems to be absorbed by the red corpuscles, which assume a chocolate-brown colour, and become functionally powerless in consequence of the formation of methæmoglobin. This elective action of the nitrites explains, according to Binz, their caustic action on the intestine when they are applied to the skin, and also their paralytic effect on the nerve centres.

COCO-NUT AS A REMEDY FOR TAPEWORM.

In the Antilles the coco-nut is a popular native remedy for tapeworm, and its utility has been proved by Dr. Martiali, chief of the medical service at Senegal. A nut of the coco (Coco crucifera) weighs about five ounces, and the whole of this is taken, scraped, and three hours afterwards a dose of castor oil is administered. The worm comes away five or six hours after the dose of coco-nut. In nine cases in which it was given the remedy was successful.

PILOCARPIN IN FETID PERSPIRATION.

M. Armaingaud of Bordeaux, in a communication to the Académie de Médecine, asserts that repeated hypodermic injections of pilocarpin will cure the troublesome fetid perspiration of the feet without producing any injurious effect on the system. Prolonged observations on three patients have convinced him that the effect is permanent, and not temporary. The pilocarpin appears to act by producing a "derivative hypersecretion" in the salivary glands; and the general sudorific action, which can be obtained much more surely with jaborandi than with pilocarpin, cannot be advantageously substituted for the sialologue action of the latter.

EUGENOL.

The antiseptic properties of oil of cloves and oil of peppermint have long been known, since they have often been employed to prevent starch, &c., from becoming mouldy. They have also been employed as remedies for toothache. Eugenol, which is extracted from these oils, and which is also known as eugenic or caryophyllic acid, is found to have similar powerful antiseptic properties. It has a formula $C_{10}H_{12}O_2$.

THE COLLEGE OF SURGEONS.

At a quarterly meeting of the Council, held on Wednesday last, the report of the Erasmus Wilson Committee, recommending the award of sixty guineas to Mr. Butlin for his two lectures on the Relations of Sarcoma to Carcinoma, and the award of thirty guineas to Mr. Frederick Treves for his lecture on the Pathology of Scrofulous Affections of Lymphatic Glands, was adopted.

The third report of the Committee on the necessary arrangements for the institution of additional examinations for the diplomas of Member and Fellow, was likewise adopted. (See also The Lancet January 15th, 1881.)

It was resolved to appoint a "Nomination Committee," consisting of seven members of the Council, to nominate candidates for the several examinerships of the College, excepting candidates for the Court of Examiners, and for the Court of Examiners' section of the Dental Board.

The Jacksonian Prize was awarded to W. Watson Cheyne, F.R.C.S., for an essay on the History, Principles, Practice, and Results of Antiseptic Surgery.

MEDICAL NOTES IN PARLIAMENT.

In the House of Commons, on Thursday, the 7th instant, petitions for inquiry into the Indian Army Medical Department were presented from W. Morgan, D. M. Jack, and D. N. Martin. A copy was ordered, on the motion of Mr. Ashley, of further correspondence relating to hospitals for British seamen in foreign ports. Notice of amendments in Committee on the Metropolitan Open Spaces Bill was given by Mr. W. H. James, and on the Alkali Works Regulation Bill a large number of amendments was put down by Earl Percy.

Indian Quinine.

On Friday, Captain Price asked the Secretary of State for India whether it was the fact that the Indian Goverment were exporting large quantities of cinchona bark for sale in London; and whether, in introducing the cinchona plant into India, the Government did so with the object of encouraging private enterprise, or of competing in the market with the private trade. The Marquis of Hartington said the object of the Government in introducing cinchona into India was to provide an abundant supply of a cheap febrifuge in the country. Almost all the bark produced in the Bengal plantations was manufactured in India for use there, but difficulty had been found in treating the produce of the Madras plantations in the same way as that of the Bengal plantations. For this reason the greater part of it was sent to England, and it was believed that the sale of this bark had established a reputation for the Indian growths to the great advantage of private growers; but an experiment was now being made on a large scale with a view to its manufacture in England on Government account, and if that experiment were successful it was probable the sale would be discontinued.

Small-pox Statistics.

Mr. Puleston asked the President of the Local Government Board whether he could give any statistics showing the extent of the present small-pox epidemic; whether this disease was more prevalent than in former years; and if it was, whether he would cause such temporary hospitals to be erected for small-pox patients as were put up during the epidemic of 1877. Mr. Dodson replied that at so short a notice he could not give precise statistics on the extent of the epidemic, but up to the present time it had not been fatal in any appreciable degree except in the metropolis. It was unfortunately more prevalent in the metropolis than on an average of years. As compared with recent epidemics, it was believed that the present would about rank with 1877–78, or 1866–67; but it was not anything like as fatal as that of 1871–72. The Board had recommended the local authorities to provide temporary accommodation as far as practicable, and that had already been done, or was in progress in some instances.

"MISSED LABOUR."

To the Editor of THE LANCET.

SIR,—I venture to ask your indulgence for a few words in reference to the editorial comment in your last issue upon my case of so-called "missed labour." You cite "the ingenious theory of" my friend "Dr. Roper, that cases of missed labour are cases in which rupture of the uterus had taken place, and the child had escaped through the rent into the surrounding tissues or abdominal cavity. In the case observed by Dr. Barnes, he seems to have convinced himself that the fœtus was in the cavity of the uterus by the introduction of the hand into that cavity......The theory of Dr. Roper is not incompatible with Dr. Barnes' observations, and the question cannot be settled but by careful post-mortem investigation."

I do not think it judicious to exclude Dr. Roper's hypothesis as explaining some cases; but as applied to my case I submit that it is rather far-fetched; it is an example of that fallacy in logic which seeks to substitute for a simple and natural explanation one that is extraordinary and improbable. I cannot accept this explanation even from Dr. Roper, to whose clinical sagacity I am indebted for much knowledge.

To argue that the question can only be settled by post-mortem examination is really to beg the question. In such cases as may be explained by Dr. Roper's theory death is a probable issue, and the opportunity of dissection may arise; but uterine pregnancy generally terminates in recovery, and happily dissection cannot be appealed to. I submit that my patient recovered because the gestation was uterine.

Deeply as the case interested me, and difficult as the pathological problem it presented seemed to be, I confess I was not anxious to solve it by a post-mortem examination. The solution given by repeated and varied examinations during life and the issue in recovery satisfies alike my ambition as a physician and my curiosity as a pathologist.

I am, Sir, yours &c.,

Harley-street, April, 1881. ROBERT BARNES.

CYSTICERCUS IN THE BRAIN.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Saturday last Dr. Flint, of Scarborough, published an interesting case of cysticercus cellulosæ in the ventricle of the brain occurring in a boy aged seventeen; giving rise to no marked symptoms during life, but apparently causing almost sudden death with acute and peculiar cerebral symptoms. As Dr. Flint seems to consider his case almost as unique as it is interesting, it seems to me worth while to refer to two others, notes of which were published with drawings of the specimens in the Transactions of the Bristol Medico-Chirurgical Society, 1878.

The first occurred in my own practice, and was published by me in 1859. The patient was a woman, aged twenty-nine. Otherwise healthy, strong, and active. For eighteen months she suffered from gastric irritation with vomesis and headache, with great febrile excitement when the attacks—seldom absent more than a few days—came on. Various forms of treatment had been tried by Dr. Mortimer Granville, under whose care she was, but without much benefit, change of air and chalybeates alone seeming to procure any abatement in the symptoms. Subsequently she became my patient in the infirmary. She could not bear to lift her head from the pillow on account of a dead, dull, heavy pain and sense of weight, nor move it because of excessive pain and stiffness in her neck. Subsequently she stated she could not open her eyes, and had all the appearance of being very hysterical; and, being strongly impressed with the idea that she was dying, returned home. Five days afterwards, while supposed to be sleeping, she was found to be dead. A cyst about an inch in diameter was found lodged in the fourth ventricle, the roof of which was much softened. The cyst contained a white semi-opaque mass, a quarter of an inch in length, and what appeared like a twisted tube protruding from it, containing fluid. On removing the end of this tube it was seen to contain the head and neck of a tænia about a quarter of an inch in length. The head has four suckers, and the corona of hooklets characteristic of tænia, and the neck, which is clearly and distinctly segmented, ends in a sort of bulb.

The second case occurred in the practice of Dr. Shingleton Smith at the Infirmary, the patient being a girl sixteen years of age. She had complained for a month, but only gave up work as a servant a week before admission. The first symptom noticed was headache frequently recurring; her look was healthy, but she seemed listless and apathetic. She became subject to attacks of severe pain across the forehead lasting only a few minutes, with flushing; then copious perspiration and a short sleep; vomiting frequently followed an attack. After six weeks the attacks were followed by drowsiness; pulse 40 to 50; then an attack of convulsions affected the right side, and the vomesis was frequent. In a second attack of convulsions she died. A cyst was found in the lateral ventricle, loosely attached to the choroid plexus. It consisted of an abdominal sac three-quarters of an inch in diameter, with an elongated projection half an inch in length; a thin layer of membrane enveloped the whole length of the head and neck, and obscured the suckers and hooklets. A dark spot, however, could be seen at the distal end of the narrowed part of the object, which, with a pocket lens, resolved itself into a dark central mass, with four smaller ones arranged around it.

My object being simply to afford your readers an opportunity of comparing these two cases with that published by Dr. Flint, I refrain from alluding to the several points of interest such comparison seems to afford.—Yours, &c.,

F. BRITTAN, M.D.,

Clifton, April, 1881. Consulting Physician, Bristol Royal Infirmary.

"THE CONSULTATIONS OF DRS. QUAIN AND KIDD."

To the Editor of THE LANCET.

SIR,—In your issue of the 9th inst. I noticed some remarks elicited by the consultation between Dr. Quain and myself upon the illness of Lord Beaconsfield, in which you question the professional morality of the proceeding and challenge a justification of our conduct. Speaking for myself, may I tender the following reply?

1. Although, to quote your own words, "a reputed homœo-

path," I desire once for all to disclaim any such special party designation. Four years ago I resigned all connexion with the Homœopathic Hospital and Society. In a very extensive practice during thirty-four years I have always adopted that course of treatment which my own experience has taught me to be most effective for the cure of my patients. Herein I claim simply to have acted as any man does who is not bound by the trammels of a merely mechanical routine. Like other practitioners, I use the drugs of the British Pharmacopœia, but in many cases I have learned from experience that what are called homœopathic remedies may be usefully prescribed. Such remedies I freely use in suitable cases and according to my own judgment. I do not prescribe infinitesimal doses, nor according to the caprice of my patients.

2. With regard to the co-operation of Dr. Quain with myself, the facts are as follows:—A valuable life was at stake, one precious to her most gracious Majesty the Queen, and to many millions of her subjects. I had been enabled for nearly four years to afford prompt and effectual relief to that illustrious man in many severe illnesses. From the first moment of the present attack I recognised its gravity and danger. For ten nights and days I bore the strain of incessant attention, then her Majesty wished that the responsibility of so momentous an illness should be shared in consultation. I was asked to arrange it. Knowing the satisfaction it would give her Majesty to have Sir W. Jenner's co-operation and opinion, I at once wrote to him. Without inquiring as to the manner in which I was treating the patient, Sir W. Jenner declined to meet me, on the ground that (quoting his own words)—"holding as you and I do different views as to practical treatment, I do not think Lord Beaconsfield's interest could in any way be served by our meeting in consultation; on the contrary, it could not be without risk to him." Before receiving his answer, however, Lord Beaconsfield expressly desired to see Dr. Quain. He communicated with me as to how I was treating the case, and upon receiving my assurance that it was not homœopathically, he without hesitation visited the patient, and so fulfilled the spirit (to use your own words) of that boast of the medical profession that in the hour of sickness it recognises only humanity in need of succour. In this way Dr. Quain and I did not work together without being agreed, nor did either sacrifice his convictions to effect the co-operation. On the contrary, Dr. Quain's great skill was thus made useful to our illustrious patient, and my intimate knowledge of his constitution and of the disease was as helpful to Dr. Quain.

3. As to the rules of professional etiquette which you maintain have herein been violated, it is impossible within the limits of this letter to discuss the entire question, but of this at least I am convinced, that if that "boast of the medical profession"—which you so fully endorse—is henceforth to remain a living principle of conduct, we must be guided not by the misleading flicker of prejudice and jealousy, but rather by the clear and convincing light of humanity and common sense.

Believe me, yours faithfully,

J. Kidd, M.D.

George-street, Hanover-square, April 12th, 1881.

⁂ Then there must be strange errors in the published reports of the Homœopathic Hospital. The report for 1879–80 lies before us, and in it we find Dr. Kidd's name as a "Benefactor," in addition to which he is credited with a donation for 1879, and another for 1880. Until recently the name "Joseph Kidd, M.D., M.R.C.S.," appeared *first* in the List of the "Medical Council" of the Hospital. Again, in the "British Homœopathic Medical Directory, 1881," under the head "List of Qualified Physicians and Surgeons practising Homœopathy," &c., we find Dr. Kidd's name and address with the hours at which he may be consulted at his professional residences. His name also appears under the head "Homœopathic Practitioners," in the "Plain Directions for the Treatment of Common Complaints," and Homœopathic Medical Directory, issued by Messrs. Leath and Ross, Homœopathic Chemists. Those facts need explanation. We cannot discuss the question of ethics—we cannot call it etiquette—with Dr. Kidd. We differ on fundamental principles; and to these principles as set forth in our article of last week we adhere.—Ed. L.

ABERDEEN.

(*From our own Correspondent.*)

On April 1st an outbreak of a disease presenting many features of novelty occurred in Aberdeen, breaking out nearly simultaneously in several families, and attacking a considerable number of individuals in each. Cases occurred in rapid succession in all parts of the town, until by the 8th of April about fifty families and over a hundred and fifty individuals had been affected. At first it was somewhat puzzling to account for the outbreak; but after a day or two it became apparent that it was connected with the milk supply, and the further observation of the disease confirmed this impression, for the families affected were scattered widely over the town, and had only one thing in common—viz., that they all obtained their milk from one large dairy farm in the neighbourhood of the town. Inquiry has shown that about one-half of the families obtaining milk from this source have been infected, while no similar cases (as far as is yet known) have occurred elsewhere in the town.

The symptoms in most cases have begun suddenly with a sharp onset of fever—chilliness followed by hot dry skin and high temperature,—the thermometer frequently marking 103° and 104°, and sometimes even nearly 105°. Headache and pain in the back, particularly the former, have very uniformly been present, and sometimes the headache has been very severe and persistent. In one or two cases delirium has been present. Along with the headache there has usually been more or less sickness, and very often vomiting, after which the stomach has remained inactive, food being refused, and this condition remaining till the disease has passed away. The tongue at first coated with a white fur, not usually very thick, and in cases where the symptoms were prolonged, and especially where much weakness was present, it became dry and brownish. The pulse rose at once at the commencement of the attack, and ranged usually about 100, but in weakly patients it rose to 120, and even somewhat higher. Sore-throat has uniformly been present to a greater or less extent. This has begun with a feeling of stiffness and soreness about the angle of the jaw, and a difficulty in swallowing or a feeling as if something were in the throat. The fauces have been more or less reddened, sometimes but slightly, at other times brightly injected, but without any appearance of exudation, and generally with little, often no swelling, the redness extending over the uvula, the lower margin of the soft palate, the tonsils and pillars of the throat, and occasionally the back of the pharynx. Externally there has been marked swelling behind and below the angle of the jaw, sometimes on one side only, sometimes on both, and not unfrequently appearing on one side, and after that subsided, appearing on the other. In a few cases a herpetic eruption has shown itself about the lips and inside of the mouth. In one or two cases there was a slight attack of diarrhœa, but it appeared to be merely a casual complication. In one case the lymphatic glands at the lower part of the neck were enlarged, and in another the right inguinal glands were enlarged. The period of greatest severity of the attack has been the first twenty-four or forty-eight hours, after which the symptoms gradually subsided. Relapses, however, have been frequent, especially when the swelling, after subsiding on one side of the throat has shown itself on the other; but usually the second attack has been less severe than the first. Whether any sequelæ may occur remains to be seen; but a considerable number of the cases seem now to be convalescent, having lasted from three or four to five or six days. Where the system was previously weak the disease seems to have been most prolonged; or perhaps it might be more correct to say that the subsidence of the attack has left more or less debility and prostration, from which when the patient was weak, and especially when he was elderly, there has been considerable difficulty in obtaining restoration. One fatal case has occurred, and it is not improbable that others may have to be recorded.

A careful examination is being made into the cause of the outbreak, and until that is completed it would be premature to offer any decided opinion on the subject. In the meantime, however, it may be stated that the cows (forty-six in number) at the dairy farm whence all the families attacked receive milk, seem in excellent health; that no addition to the dairy stock has been made since November; that the byres are large and airy, in every way unexceptionable in structure, and that everything about the dairy-house is clean and well kept. In one point, however, there is a serious defect. The water used is obtained from the Dee, being part of the water supply for the town of Aberdeen, which is extremely pure; and chemical examination has shown that it reaches the farm entirely uncontaminated. The supply pipe is led into a large cistern made of concrete, from which it is distributed to the byre, stable, dairy, &c. This cistern is placed within the byre, supported on beams in one corner, and placed at such a height as not to be in the way of the cows or their feeding-troughs. No doubt it is covered with a wooden cover, but this is very far from fitting air-tight; and as the byre is open from end to end, the air loaded with exhalations from the animals, from their food, their bedding, &c., finds free access to the water in the tank. Chemical examination has shown that the water in the cistern is seriously contaminated with albuminoid ammonia, nitrates, and excess of chlorides; and this, as direct sewage contamination is impossible, has evidently been derived from the air in the byre. Whether this has been the cause of the outbreak remains to be seen, but it is plain that an arrangement which subjects the water to such contamination is in every way most objectionable.

IRELAND.

(*From our own Correspondent.*)

THE Cork medical libel case, which was tried last week at Cork before Mr. Justice Barry and a special jury, terminated by the jury disagreeing.

During the past year the total number of patients treated at the Hospital for Women and Children, Cork, was 123 in excess of the number under treatment in 1879. The Board of Management, in their annual report, regret that the inadequate size of the present hospital building and want of funds prevent them from developing the usefulness of the institution. They also regret that the hospital has not received that support from the general public during the past year that was expected; on the contrary, the gross receipts of 1880 have fallen below those of 1879 by the sum of £107 19*s.* 8*d.*

An adjourned meeting of the Dublin Ladies' Sanitary Association took place last week, for the purpose of receiving a report from the Provisional Committee recently appointed, and to take measures for the permanent establishment of the association. It is proposed to carry out the objects of the association by the distribution of pamphlets, the delivery of lectures on health, sanitary improvements, and domestic economy, the establishment of a lending library of books, the formation of classes for adult girls, instruction in schools on hygienic and domestic matters, and the encouragement of neatness and cleanliness in the rooms and houses of the poor.

The plan of organisation of the Royal University of Ireland as adopted by the Senate differs but slightly—at least as regards the medical portion of the curriculum—from that proposed by the committee appointed for that purpose, and published in THE LANCET at page 504. Although as there stated, candidates for the M.D. may present themselves at the examinations for this degree at the end of two academical years from the date of obtaining the degree of M.B., yet to this arrangement must be added a regulation, that those candidates who shall be students in medicine in the Queen's University at the date of its dissolution shall be entitled, if they so desire, to obtain the degree of M.D. instead of the degree of M.B. upon passing the degree examination. There will also be an examination for a diploma in sanitary science, which will be conferred only on graduates in medicine of the University. The fee for the examination will be £2, and the examination will embrace the following subjects: —climate, chemistry, geology, physics, vital statistics, hygiene, and sanitary law.

At a recent meeting of the Committee of Management of the Cork-street Fever Hospital the registrar reported that during last month both fever and small-pox had decreased to a considerable extent, the number in the house that week being under forty, and none of the cases were of a severe type. The Committee are anxious, while the numbers are so low, to clear out the present convalescent house, which is unsuitable in many ways, and remodel the same according to modern requirements, but the necessary expenditure deters them for the present. There was only one case of small-pox under treatment in the principal Dublin hospitals for the week ending the 2nd inst.

The Corporation of Dublin do not appear to regard with satisfaction the recent conjoint report of the Colleges of Physicians and Surgeons on the death-rate of the city, most probably due to the belief that the Colleges consider that the sanitary authority have not been sufficiently active in utilising the powers they are entrusted with. At a recent meeting of the Town Council the conjoint report was recived and the following resolution in reference thereto was adopted:—"That in acknowledging the reports of the united colleges of the King and Queen's Colleges of Physicians and the Royal College of Surgeons on the death-rate of Dublin, the Corporation wish to thank the Colleges for their report, and to point out that the report contains no new matter or suggestions on matters of public health to which the notice of the Corporation had not been previouly directed by the report of the Public Health Committee, dated August, 1880, and that all of the said suggestions, so far as the executive powers of the Corporation extend, have been acted on for many months previous to the issue of the reports of the Colleges, except that of the main drainage, which, in the opinion of the Royal Commissioneers, should follow the more urgent and possible reforms, and that the said report be forwarded to the Public Health Committee for further report thereon as to extended legislation to improve public health, and as to such reforms as will in great measure depend on the extension of municipal boundaries."

Obituary.

SURGEON-MAJOR G. F. FORBES.

DR. FORBES, whose death was announced in our obituary list of March 26th, belonged to the Forbeses of Millburn, near Inverness, and was brother of the late Dr. William Welsh Forbes. The greater part of his life was spent in India, and about fifteen years ago he was employed by Government as a Commissioner in connexion with the growth of cotton both in India and America. He passed through the troubles connected with the Indian Mutiny, and also saw service in the first Afghan War. Shortly after the completion of the Government engagement, he retired from active service. The deceased (says the *Aberdeen Herald*) lately endowed a medical dispensary, founded in Inverness by his brother, with a sum of £6000, which was lately handed over to trustees on behalf of that institution, and it is understood that his native county will benefit further by his benefactions. The provost, magistrates, and members of the Town Council attended the funeral, and the shops and places of business of Inverness were closed in token of respect for the deceased. The Forbes Memorial fountain, which he had presented to the town, was draped in black.

ADELAIDE HOSPITAL, DUBLIN.—During the past year 875 patients were admitted into the hospital, and the average number of beds in daily occupation throughout 1880 was 78. The special attention of the Committee has for some time past been devoted to providing a nursing staff sufficient for the proper care of the patients both by day and night; and the subdivision of the wards for the proper classification of disease has rendered it necessary to employ a larger number of nurses than in similar institutions. The sum expended in the maintenance of the hospital for the year amounted to £5258; while £1588 was received by subscriptions, £1598 by donations, £919 by bequests, and £867 from pay patients. A debt of nearly £3000 still remains, but this sum will be much reduced when some large bequests have been received.

NEWCASTLE INFIRMARY.—At the annual Court of Governors of this institution, held on the 7th inst., reference was made to the great pressure experienced on the accommodation afforded by the building, so that its enlargement would soon become an absolute necessity. On the representation of the infirmary authorities, it was stated that the Schools and Charities Committee have set apart suitable premises, and taken other measures, for founding a Hospital for Incurables in Newcastle.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners on the 7th, 8th, 11th, and 12th inst.:—

David L. Williams, Percy W. McD. Howse, Frederick H. Taylor, William A. Nutt, Walter Blaxland, Alfred T. Schofield, John Bostock, David Thomas, and Victor N. Bindley, London Hospital; Vere L. Oliver, George D. Hunter, Alfred T. I. Lilly, and Herbert W. Allingham, St. George's Hospital; Sydney S. Merrifield, Gerald G. Hodgson, A. H. Gordon, Herbert C. McDouall, Alfred M. Vann, Cecil D. Greenwood, and Thomas W. S. Morgan, King's College; Charles K. Bond, George D. Johnston, and Walter G. B. Tyrrell, Yasuzumi Saneyoshi, Frederick F. Caiger, Bernard Kelton, and Henry B. Robinson, St. Thomas's Hospital; Herbert Larder and Paul Jackson, Westminster Hospital; William A. Russell, Walter Spencer, Arthur E. Huxtable, John Marriott, John H. Crocker, Walter H. Haw, Howard Davies, and Alfred Turner, Charing-cross Hospital; Edward J. Cave, Francis Cresswell, Thomas E. Lovegrove, Thomas W. Shore, John F. Steedman, and Arnold Lyndon, St. Bartholomew's Hospital; George M. P. Braine, William W. Linney, Percy W. Smith, William H. Crags, and Albert E. Rook, Middlesex Hospital; Edgar E. Masters, Herbert E. Counsell, and George A. Johnson, Guy's Hospital; Alfred T. Masters, Charles H. Hall, and Edmund P. Cockey, St. Mary's Hospital; Thomas F. Gardner, Frank Hinds, Arthur F. Blagg, William A. Gostling, Arthur J. Drew, Alfred J. Turner, and Evan Williams, University College; Albert Martin and George H. Rodman, Guy's Hospital; William Bradbrook, Owen C. Jones, and James D. Llewellyn, London Hospital; Harry J. Thornton and Henry W. M. Kendall, Middlesex Hospital; Benjamin W. Thomas and Ernest Atkins, Charing-cross Hospital; Richard Andrews and John P. Glover, St. Thomas's Hospital; Horace H. Pinching, St. George's Hospital; Henry H. Wigg and Herbert R. Spencer, University College; Charles Childe and Charles T. Dornford, King's College; Frederick A. Rogers, St. Mary's Hospital; Edmund C. Pettifer, John R. Nunn, and Edward C. Sharpin, St. Bartholomew's Hospital, George H. Phillips, University College and Charing-cross Hospital.

[In the list published last week of gentlemen who passed the Primary Examination, the name "Arthur W. Davison" should have been Arthur Willan Dawson.]

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on April 7th:—

Anderson, Daniel Elie, Harrington-square.
Dashwood, Edmund Samuel, Merrick-square, Borough.
Hodges, James, Henley-on-Thames.
Tibbles, William, Wayford-street, Battersea.

The following gentlemen also on the same day passed the Primary Professional Examination:—

John Bourne Berry and William Skilbeck Stables, Guy's Hospital; Ebenezer Thomas Smith, London Hospital.

THE Manchester Board of Guardians have made a grant of £50 to St. Mary's Hospital of that city.

A GRAND Fancy Fair and Tableaux Vivants will be held on the 19th inst. and following day, in aid of the enlargement of the National Eye and Ear Infirmary, Dublin.

THE Library of the Royal Medical and Chirurgical Society will be closed from Thursday evening, the 14th inst., until Tuesday morning next, the 19th inst.

A LADY has placed at the disposal of Dr. Greig Smith, one of the surgeons of the Bristol Royal Infirmary, a gift of £5, for providing additional comforts for the patients.

THE funds of the Poplar Hospital have benefited to the amount of £20 7*s.* 6*d.*, the proceeds of a concert given at the Town Hall, Poplar, last month.

CAMBRIDGE UNIVERSITY.—At a Congregation on the 7th inst., the degree of Bachelor of Medicine was conferred on Donald McAllister, M.A., St. John's College.

THE name of Mr. John Bowes, L.R.C.P. Lond., should have been included last week in the list of gentlemen presented at the levée on the 5th inst.

AT the Quarterly Meeting of the Directors of the Compassionate Branch of the Naval Medical Supplemental Fund, Sir W. R. Smart, K.C.B., M.D., Inspector General, in the chair, the sum of £37 was distributed among the several applicants.

THE difficulty of obtaining a proper supply of water has rendered useless the site recently purchased, at a cost of £5000, for the erection of a new lunatic asylum at Witham, Essex. The county magistrates have accordingly resolved to enlarge the present building, and leave the question of the appropriation of the fresh site to be settled on a future occasion.

AT the quarterly court of governors of Addenbrooke's Hospital, Cambridge, the attention of the medical officer was directed to the increase in the average length of time during which in-door patients are retained in the hospital.

WE are asked to state that the prizes offered by the Société contre l'Abus du Tabac, for the concours of 1880, will be awarded on May 8th next. For the concours of 1881, the Society offers one prize of 300 fr., three prizes of 200 fr., and one of 100 fr., also silver and bronze medals and books.

IN token of their obligation to Dr. Bell of Bradford, for the part he has taken in the investigation of the malady known as "woolsorters' disease," the woolsorters of the district are about to present to that gentleman an illuminated address and a handsome gold watch.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES. Mrs. Seymour, of Great Shelford, bequeathed £200 to the Addenbrooke's Hospital, Cambridge. Mr. J. W. Dod has offered, conditionally, £1000 towards relieving the Bristol Infirmary from its debt.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—The Prince of Wales, having to be present at the wedding of the Crown Prince of Austria in Vienna on May 10th, has desired that the festival dinner of the above hospital shall be postponed from the 9th to the 24th of May, in order that his Royal Highness may preside.

AMERICAN MUNIFICENCE.—It is stated that the Hon. T. A. Scott has presented 50,000 dollars each to the University and Jefferson Medical College, and 30,000 dollars to the Orthopedic Hospital, Philadelphia. Mr. George Seney, of Brooklyn, has given 200,000 dollars and a site worth 70,000 dollars, in addition to several other valuable lots, for the purpose of erecting and maintaining a new hospital in that city.

SIR PATRICK DUN'S HOSPITAL, DUBLIN.—During the past year there has been a deficiency in the income from non-payment of rents on Sir Patrick Dun's estate of £600, and in the year preceding of £400 from the same cause. Notwithstanding this diminution of income, not a single ward has been closed during the year, and the daily average of beds occupied amounted to 70. This result was, however, obtained only by the sale of certain securities.

SUITABLE premises have been taken at Wolverhampton for the purpose of establishing an Infirmary for Diseases of the Eye. The nearest hospitals for residents in the above-named town are situated at Birmingham and Shrewsbury, and the need in Wolverhampton of such an institution as that proposed has, it is stated, been long experienced. Subscriptions in aid of the project have been liberally supplied, and no doubt is felt as to a sufficiency of funds being forthcoming.

VACCINATION GRANTS.—The following gentlemen have received the Government grant for successful vaccination in their respective districts:—Mr. John H. Wraith, Darwen district of the Blackburn Union (third time). Dr. John Dearden, Church, near Accrington (fourth time). Mr. J. Wardleworth, Bury Union. Mr. W. Moxon, Matlock district of the Bakewell Union, Derbyshire. Dr. Fentem, Bakewell district of the Bakewell Union (second time). Mr. H. Laver, Colchester.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest.*

ARMSON, C. G., L.F.P.S.G. & L.M., has been appointed Medical Officer and Public Vaccinator for the Yoxall District of the Lichfield Union.

AUSTIN, C., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the First South-Eastern District of the Freebridge Lynn Union.

BARNES, L. J. J., M.D., L.R.C.S.I., has been appointed Medical Officer to the Second B District of the Dartford Union.

BUTTERFIELD, H., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Bradford Urban Sanitary District.

CAFFYN, S. M., M.R.C.S.E., has been appointed Government Medical Officer for the District of Illawarra, New South Wales; Surgeon to the Albert Memorial Hospital, Mount Kiera Colliery, and Illawarra Lodge of Odd Fellows.

CLARE, E. S. N., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Third District of the Calne Union.

COLLIER, W., M.B., M.R.C.S.E., has been appointed Junior Residen Medical Officer to the Radcliffe Infirmary, Oxford.

CURETON, E., L.R.C.P.Ed., has been appointed Physician to the Salop Infirmary, vice H. N. Edwards, L.R.C.P.Ed., resigned.

DE WATTEVILLE, A., M.A., B.Sc., M.R.C.S.E., has been appointed Medical Electrician to St. Mary's Hospital.

DOUGHTY, W., L.R.C.P.Ed., has been appointed Medical Officer to the Wetherall District of the Carlisle Union.

FITZGERALD, W. A., M.D., L.R.C.S.I., has been appointed Assistant House-Surgeon to the Royal London Ophthalmic Hospital, Moorfields.

FRASER, D. A., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health for the Burnham Urban Sanitary District.

GROGONO, W. A., L.R.C.P.Ed., M.R.C.S.E., L.S.A.L., has been appointed, temporarily, Medical Officer to the St. George's-in-the-East Industrial Schools, vice Levick, deceased.

HINE, J. C., M.B., M.R.C.S.E., has been appointed Senior Resident Medical Officer to the Radcliffe Infirmary, Oxford.

LILLEY, G. H., M.D., M.R.C.S.E., has been appointed Assistant-Surgeon to Her Majesty's Convict Prison, Portland.

MAVER, D., M.B., C.M., has been appointed Medical Officer of the Newhills and Dyce Medical Association, vice Carlyle, resigned.

MILLES, W. J., F.R.C.S., L.R.C.P., has been appointed House-Surgeon to the Royal London Ophthalmic Hospital, Moorfields.

NEWSHOLME, A., M.B., M.R.C.S.E., has been appointed Surgeon to the City Dispensary, vice Kingdon, resigned.

NEWTON-CLARE, E. S., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Third District of the Calne Union.

PARTRIDGE, T., M.K.Q.C.P.I., M.R.C.S.E., L.S.A.L., has been re-appointed Medical Officer of Health for the Stroud Rural and Urban and the Besley Urban Sanitary Districts.

RAMSAY, W., L.R.C.P.Ed., L.R.C.S.Ed., has been reappointed Medical Officer and Public Vaccinator for the Sherburn District of the Scarborough Union.

ROBSON, E. S., L.R.C.P.Ed., has been appointed Medical Officer to the Eastern District of the Durham Union.

SHEARS, A., M.D., M.R.C.S.E., has been appointed Medical Officer in the Civil Service of Tobago, West Indies.

[ERRATUM.—In the announcement last week of the appointment of Mr. Anderson Critchett to the Ophthalmic Surgeoncy of St. Mary's Hospital, the name of his predecessor was given as "Wharton Jones." It should have been, vice Haynes Walton.]

Births, Marriages, and Deaths.

BIRTHS.

BARRON.—On the 10th inst., at 13, Church-street, Southport, the wife of H. G. Barron, B.A. Oxon., M.R.C.S.E., L.R.C.P.L., of a daughter.

DUKE.—On the 8th inst., at Cornwall-road, Westbourne-park, W., the wife of G. Amos Duke, M.R.C.S.E., of a son.

DUNLOP.—On the 9th inst., at 50, David-place, Jersey, the wife of Dr. Dunlop, of a son.

KYNGDON.—On the 10th inst., at St. Leonard's, North Shore, Sydney New South Wales, the wife of F. H. Kyngdon, Esq., M.D., of a son.

LITTELJOHN.—On the 1st inst., at Hanwell, Middlesex, the wife of Saltern G. Litteljohn, M.B., of a son.

MARRIAGES.

DYER—STEPHENS.—On the 5th inst., at St. George's, Hanover-square, Thomas Birch Dyer, M.D., of Darenth, Kent, to Mary Jane, third daughter of Edward Stephens, of Morton-road, Canonbury.

GREVES—SOUTHAM.—On the 7th inst., at St. Giles's, Shrewsbury, Hyla Greves, M.B., C.M., of Liverpool, only son of E. T. Greves, of Carlton-road, Maida-vale, London, to Agnes Emily, fourth daughter of Thomas Southam, of The Hollies, Shrewsbury.

INKSTER—CLARKE.—On the 7th inst., at St. Stephen's, Hampstead, Macauley Inkster, M.D., of Sheffield, to Amy, eldest daughter of Henry Clarke, Esq., of Belsize-avenue, Hampstead.

JUKES—POYNTER.—On the 3rd ult., at Kurrachi, India, Andrew Jukes, L.R.C.P., Med. Missionary to the Beloches, Dera-Ghazi-Khan, son of the late Rev. M. R. Jukes, to Anna Jane, second surviving daughter of Samuel Poynter, of Crouchmans, North Shoebury, Essex.

DEATHS.

CRELLIN.—On the 8th inst., at Parkside, Richmond, Surrey, Horatio Nelson Crellin, M.R.C.S.E., aged 82.

HULKE.—On the 10th inst., suddenly, at Admiralty House, Deal, Frederick Thomas Hulke, M.B., J.P., aged 47.

WATCHORN.—On the 13th inst., at Sandfield House, Nottingham, Isaac Watchorn, M.D., aged 48.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, April 18.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

Tuesday, April 19.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

PATHOLOGICAL SOCIETY OF LONDON.—8½ P.M. The following specimens will be shown:—Cylindroma of the Popliteal Space; Specimens of Rectal Cancer; Villous Polyp of the Bladder; Liver Abscess following Dysentery; Cirrhosis of Liver in a Child with Congenital Hydrocele; Fractured Cervical Spine; Two Cases of Intestinal Obstruction; Heart with Calcareous Plates; Sarcoma of Kidney from a Child; Gangrene of Lung following Amputation of Tongue (card); Heart with Stenosis of Tricuspid Valve; Multiple Sarcomata of Skull.

Wednesday, April 20.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.—7.45 P.M. Council Meeting: "Casual Communications."

HUNTERIAN SOCIETY.—8 P.M. Mr. F. Treves, "On the Diagnosis and Treatment of Scrofulous and Lymphatic Glands."

Thursday, April 21.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

HARVEIAN SOCIETY.—8½ P.M. Mr. Henry Morris, "On some Cases of Fibrous Polypi of the Nose and the operative treatment of them."—Mr. Teevan, "On Difficult Micturition from Prostatic Disease."

Friday, April 22.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

QUEKETT MICROSCOPICAL CLUB.—8 P.M. Mr. T. Charteis White, "On the Histology of the Gustatory Organs of the Rabbit's Tongue."

CLINICAL SOCIETY OF LONDON.—8½ P.M. Dr. W. J. Tyson, "On a Case of Cross-legged Progression."—Dr. W. Stokes (Dublin), "On Cases of Excision of the Tongue."—Dr. Whipham, "On Aortic Aneurism Demonstrated by the Laryngoscope."—Dr. T. Stretch Dowse, "On a Case of Anorexia Nervosa."

Saturday, April 23.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

A WHOLESALE DISTRIBUTION OF COFFINS.

THE Municipal Special Committee of Hygiene entrusted with the difficult task of preserving public health at Rome allude in their last monthly report to a form of generosity which is not altogether encouraging. We are told with some unction that, though there were only 722 deaths in the month of February, no less than 525 coffins have been distributed gratuitously to the poor! Further, we are informed that the number of these sinister donations was greater during the preceding month of December. As a contrast, we find that the assistance in medicaments given was equivalent during the month to only £88. The parish, or municipal, doctors attended 1386 poor, of whom 950 were already under their care during the previous month. Thus we find that measures for the interment of the dead rather than the preservation of the living hold the most prominent place in the report. Yet we should mention that something has been done with respect to house inspection; 301 dwellings were visited, and in 81 cases improvements in drainage, &c., were enforced. Further, 268 kilogrammes of bad meat were seized and destroyed during the month. Still, in spite of this good work, the knowledge that the Government has to distribute annually more than six thousand coffins to the poor inhabitants of the Eternal City is not calculated to enhance the attractions of Rome.

MULTIPLE ABSCESS OF THE LIVER FOLLOWING DYSENTERY.

To the Editor of THE LANCET.

SIR,—I quite agree with your Indian correspondent in THE LANCET of March 26th as to the almost universal fatality of multiple liver abscess and the little hope the operation of aspiration offers to the practitioner practically conversant with the relations of hepatitis and dysentery.

After a preliminary experience in Bengal, I started the subject at Secunderabad, which is the school in which to accumulate such knowledge. When attached to the 107th Regiment in 1874-5 my friend, Surgeon-Major W. H. Corbett, and I had some very successful cases of recovery after aspiration. On one occasion, indeed, when a first operation was likely to end badly, in consequence of air having accidentally entered through the separation of a tube, at a subsequent operation in January, 1875, finding that there was a discharge of highly offensive pus, I washed out the cavity of the abscess repeatedly with a one in forty solution of carbolic acid until the liquid came out of the aspirator as clear as when injected, and, closing the wound to exclude the air, I had a good recovery.

I had the pleasure of meeting another of my old cases last year in which I had been obliged to operate a second time. He was still in the ranks. These cases were those of the large single abscess, the consequence of hepatitis pure and simple, and occurred in a regiment which had been a long time in the country.

When attached to the 12th Lancers, in 1877-8, I had an opportunity of studying the effect of the climate on a young regiment fresh from England. Though many operations for the relief of hepatic abscess were attempted, they all failed, as the cases were those of multiple abscess consequent on dysentery. Nature performed two operations successfully, but even with her the cases were those of abscess following uncomplicated hepatitis; I question if she ever does much in the way of successfully evacuating the multiple abscess which follows chronic dysentery. The post-mortem appearance is enough to negative such an opinion. It also afforded me complete insight into the cause of the failure of the operations.

JOHN E. PURDON, M.B., Surgeon-Major.
Guernsey, March 27th, 1881.

THE WEATHER OF 1880.

MR. EDWARD MAWLEY, F.M.S., has published for 1880 a work on the weather in the neighbourhood of London, similar in character to that which he issued last year on the weather of 1879, and which we commented upon very favourably. This work will prove equally as useful as the previous one, and observers—medical and other—will find it a welcome addition to their works of reference.

Mr. A. T. Searle.—We cannot recommend any physician or surgeon in particular.

Mr. F. L. C. Richardson.—We regret we have not space for the insertion of the questions.

Constant Reader.—Are the questions specified worse than the others? We think the whole thing bad, but we doubt whether the interrogations to which allusion is made are mischievously suggestive.

MEDICAL MEN AND RAILWAY COMPANIES.

To the Editor of THE LANCET.

SIR,—The judge decided a short time since in the case of Vance *v.* Tilbury Company that a servant cannot pledge his master's credit. Nevertheless the jury gave a verdict for five guineas, which carried costs, in consequence of the secretary of the company admitting he knew of the attendance by Dr. Vance on one of their firemen. It was a well fought case, and if the Employers' Liability Act had been in force matters might have been different. I believe that if "M.D." was to sue under the Employers' Liability Act he would succeed, as a station master is the recognised superintending servant of the company, and therefore has power to pledge his master's credit when it becomes incumbent upon him to protect the lives of passengers.

I will be happy to give my mite to settle so important a matter. I have been much engaged in such cases, and, indeed, with the exception of the one just named, always found railway companies pay fairly and generously. The company had no right to demand a fee from the relatives. Medical men give up much time gratuitously, but a company like the London, Chatham, and Dover Railway Company seem not only to ask for gratuitous advice, but add insult to injury to "M.D." in offering half a fee.—I remain, Sir, your obedient servant,

JOHN VANCE,
Retained consultee by various firms under the Employers' Liability Act in Canning-town and Woolwich district.
Plaistow and Victoria Docks, April 11th, 1881.

To the Editor of THE LANCET.

SIR,—I think your correspondent, "M.D.," has a just right to complain, and that he has a legal claim on the London, Chatham, and Dover Railway Company. Some time ago I was sent for to the station here, an *employé* of the Great Eastern Railway Company having met with an accident, and superintended his removal to the hospital by the next train. The company forwarded me (unasked) a guinea through their station master, with their thanks for my promptitude in attending.

I am, Sir, yours faithfully,
Newport, Essex, April 9th, 1881. HENRY J. BUCK.

"SYPHILIS AND LOCOMOTOR ATAXY."

To the Editor of THE LANCET.

SIR,—In an annotation in last week's LANCET attention is directed to a recent communication published by Erb regarding the relation of syphilis to locomotor ataxy. The facts there recorded, as well as by other writers, no doubt justify the conclusion that there must be an etiological connexion between syphilis and locomotor ataxy. But I believe that another precursor to tabes dorsalis is chronic alcoholism, and although it may not prove to enter so largely into the etiology of the disease, yet I have been of opinion for some years that chronic alcoholism plays no unimportant part in a number of these cases. I have had under treatment within the last two or three years four cases of locomotor ataxy, in which all the parents had been for years addicted to the consumption of stimulants in very large quantities, and in whom no symptoms of syphilis, as far as I could learn, ever presented themselves. I merely mention this matter as, although it may be known to some, it is omitted, so far as I am aware, in all standard works on the subject.

I am, Sir, your obedient servant,
Dublin, April 12th, 1881. CHARLES H. ROBINSON, F.R.C.S.I.

To the Editor of THE LANCET.

SIR,—In an annotation on the above subject, which appeared in THE LANCET of April 9th, you mention the names of Dr. Gowers and Professor Erb in connexion with it. May I be permitted to say that the first to call attention to the frequent dependence of locomotor ataxy upon syphilis was Professor Fournier, of Paris, who in 1876 delivered a course of lectures at the Hôpital St. Louis to prove this connexion between the two diseases. These lectures were published as a *brochure* in the same year. Professor Fournier based his views on the subject upon eighty cases of locomotor ataxy in which there was a previous history of syphilis, twenty-four of these cases having been under his own care. He found that 80 per cent. of ataxic patients had suffered from syphilis, which is nearly the same proportion as was found by Professor Erb amongst his patients.—I am, Sir, yours faithfully,

Wimpole-street, W., April 9th, 1881. W. ALLEN STURGE.

"CASES OF PNEUMONIA TREATED IN THE HOSPITAL AT CABUL."

To the Editor of THE LANCET.

SIR,—Having read Dr. Morris's account of thirty-five cases of pneumonia treated in the hospital at Cabul in your issue of March 26th, I hope he will excuse my making a few remarks on them. He ascribes them to overwork, extreme cold and want of sleep; describes the pneumonia as catarrhal and complicated with pleurisy, remittent fever, and meningitis. Now, I would suggest that the cases might have been caused by the specific blood poison of whooping-cough, which might have been dormant in the whole of the men affected until aroused into activity by the causes mentioned, or only developed in one or two of the men and communicated to the others by contagion. The variety of pneumonia is that belonging to whooping-cough, the complications the same as mentioned in my letter on the Welbeck poisoning in your issue of March 12th.

I will just give particulars of one case which seems to me to connect that form of pneumonia with whooping-cough. On Friday, November 29th, 1878, I was sent for in the evening to see A. H——, who was said to have a severe cold. As I had been past the house several times in the course of the day I sent a saline mixture, with tartrate of antimony, and saw him next morning, Saturday; he was up, but look flushed and feverish, and complained of having had chills, thirst, and headache. I examined his chest carefully and found no particular morbid sound, respiration rather quicker than natural, and at the posterior and lower part of each lung the respiratory murmur was rather louder and slightly rough. I ordered mustard plasters, to be followed by hot poultices; the next day, Sunday, December 1st, I found a mucous râle over the whole lower and back part of both lungs. I applied blisters, continued the poultices and medicine; but, to epitomise the case, the inflammation gradually spread through the whole of both lungs, fortunately for him the parts first attacked improving as the disease advanced; the delirium also was very violent, particularly at night. On Sunday, December 8th, there was an improvement, and by the following Friday, December 13th, he was convalescent.

I will mention here that in whooping-cough the exacerbations take place generally from 4 to 8 P.M., when there is an increase of cough and general malaise; from 8 to 10 or 11 P.M. there is often a slight remission; afterwards a bad night till 4 or 5 A.M.

I generally visited A. H—— during his convalescence about 6 or 7 P.M., in order to observe his wife's health; she had nursed him night and day and had not been out for some time. On December 27th, as I came to the door, I heard some one coughing violently. I went in and found her standing holding by the table in a regular fit of whooping-cough; she was coughing until she seemed to empty her chest, then taking a long respiration with the "whoop"; finally it ended in vomiting. As she had not been out the contagion evidently came from her husband; but from her having been constantly in the warm rooms it had assumed the chronic form; had she been exposed to cold she would most likely have had pneumonia, the same as her husband.

I am, Sir, yours very truly,
New Whittington, April 6th, 1881. JOHN COLSTON.

General Practitioner.—Assistants, like everybody else, should have a holiday, but a principal who cannot afford one for himself may not be able to afford one for his assistant.

TOYS FOR CHILDREN IN SMALL-POX AND FEVER HOSPITALS.

To the Editor of THE LANCET.

SIR,—There are at the present time an unusually large number of children in the Metropolitan Hospitals for small-pox and fever. These little ones much need toys and books. When they get better they cannot go home for many weeks, for fear of their giving infection to others; nor can their fathers, mothers, and friends visit them in the hospital. During these tedious weeks the children much need some amusement in the somewhat uninteresting wards. One matron from a small-pox hospital writes:—"We shall be most thankful to receive a grant of toys and books for our poor patients, as it is a thing I very much deplore that we never get anything of the kind sent to us, as other hospitals do. We generally have 140 patients, one-third being children, and I regret to say that we have no library; and from the nature of the diseases which we receive we are obliged to keep our patients (as well as *employés*) so isolated that they stand in need of amusement more than general hospitals, which have constant visitors to their wards." Another matron of a fever hospital writes:—"We have nine wards open, and the amount of pleasure your present has given you can hardly imagine; poor little sick babies, forgetting their ailments, put up their hands for a toy. It has been a delightful morning to me, giving out the toys, books, &c., and I cannot tell you how grateful I feel to you for bestowing so much pleasure on our poor patients." Surely some of those happy children who can be nursed at home, should they fall ill, will be glad to send their old toys and books to the poor little children who are removed from their homes half across London, and have to spend several weeks in a large hospital amongst strangers. Any gift of toys or books will be received by Mrs. Ward, 36, Broadhinton-road, Clapham, S.W.; or money to buy such can be paid to the Hospital Book and Toy Fund (Treasurer, H. S. Thornton, Esq.), at Messrs. Williams, Deacon, and Co., 20, Birchin-lane, E.C.—I remain, Sir, yours, &c.,

J. ERSKINE CLARKE, Vicar of Battersea.

Broughton.—1. There is an account of lime-fruit trees given in Bentley and Trimen's "Medicinal Plants," No. 52. "It grows wild in Jamaica, Tahiti, and elsewhere. Lime trees are also cultivated in Jamaica, Dominica, and largely of late years in Monserrat of the Antilles."—2. Our correspondent had better apply to Dr. Sansom concerning the "ox-blood."

X. Y. Z.—The custom varies. Our correspondent should ascertain what it is in the district in which he contemplates settling.

Luke.—Nothing less than excision.

ENGLISH MINERAL WATERS.

To the Editor of THE LANCET.

SIR,—I have been much interested by the letters which you have published on the above subject. I am a miserable dyspeptic, who finds annually immense relief from the waters of Homburg, but I confess I should gladly be able to dispense with the fatigues of a long and not very interesting journey. Can any of your correspondents suggest any English waters within a convenient distance from town as an efficient substitute for and similar to the Homburg waters in chemical composition and therapeutic action?—I am, Sir, yours, &c.,

April 11th, 1881. BRUNNEN.

DRUGGISTS' CHARGES.

To the Editor of THE LANCET.

SIR,—The counter-practice of druggists has lately been complained of as injurious to legitimate medical practitioners. This has chiefly arisen from the "general practitioner" (I prefer "surgeon") throwing dispensing into their hands.

Forty years ago, when I commenced my professional life in a small country town, surgeons not only dispensed their own prescriptions, but also those of consulting physicians, with very considerable profit, and little trouble. The drug-sellers did a modest business. Now they are pharmaceutists—great swells—grown rich—live in fine houses away from their shops, &c. The surgeons have become less in number one-half; still attend clubs at 3*s*. per annum, and midwifery at 10*s*., and 15*s*. in the country. The large majority of the population are poor, and can badly afford to pay the surgeon's fee for attendance, and the drug bill in addition. The consequence is they go to the educated and examined pharmaceutists for their minor ailments to escape the additional expense they are now put to.

All this is, in my judgment, a mistake. No family attendant should be above sending out his own remedies. It is pride interfering with pocket. The remuneration for his brain-work goes into the pocket of the mere drug-seller. Now, a word about this same drug-seller. A lady friend of mine (a widow), of small means, had occasion to consult an eminent oculist, who prescribed a ten-ounce lotion of solution of lead, borax, and almond water. For this simple lotion she was made to pay 6*s*.

I am, Sir, yours happily,
April 5th, 1881. A RETIRED SURGEON.

SUCCESSFUL REVACCINATION AFTER NATURAL COW-POX.

To the Editor of THE LANCET.

SIR,—I would suggest to Dr. Battye—1st, that the girl he mentions had not been efficiently or sufficiently vaccinated in infancy, as proved by only one mark remaining; 2nd, that the fact of her having genuine cow-pox is extremely problematical; and, 3rd, that the fact of the success of his vaccination should rather point out to Dr. Battye the truth of my first two suggestions. With your permission I will enter more fully into the subject of vaccination and cow-pox inoculation on a future occasion.—I am, Sir, your obedient servant,

Bucks, April 12th, 1881. THOMAS NEWHAM, M.D.

"DISLOCATION OF SHOULDER-JOINT AND DEATH FROM CHLOROFORM."

To the Editor of THE LANCET.

SIR,—In THE LANCET of March 26th (page 525), Mr. Lawton describes a method of reducing dislocation at the shoulder-joint, which might appear new. Will you allow me to state that twenty-six years ago I tried the same plan, and also with the jack-towel under both arms, but the lateral pressure against the ribs was so extremely uncomfortable, if not actually painful, so that I afterwards made a little apparatus which, when used, has proved most efficient.

It is simply the top rail of a common kitchen chair, with a couple of straps attached to it so as to fix it on the back below the shoulders (as in the sitting position on the chair), and the jack-towel put round it. This was exhibited at the meeting of the British Medical Association in Leeds, July, 1869, under the name of "A yoke for the back used in dislocation at the shoulder-joint," and can be obtained from Messrs. J. J. and W. Wood, surgical instrument makers, King-street, Manchester.

I am, Sir, yours, &c.,
Kendal, April 2nd, 1881. ROBT. T. LEEMING.

To the Editor of THE LANCET.

SIR,—I succeeded a short time ago in reducing with the greatest ease a dislocation of the shoulder after the administration of the nitrous oxide gas. The time occupied was just one minute—forty seconds for the gas, and ten seconds for the reduction. The shoulder had been twenty-four hours unreduced. Why give chloroform in such cases?

I am, Sir, yours, &c.,
Bristol, March 29th, 1881. ROBERT W. ELLIS, Surgeon.

FIRE-PROOF ASYLUMS.

THE *Boston Medical and Surgical Journal* of March 24th has an article on fire-proof asylums for the insane and the means at the disposal of the authorities of such institutions for the extinction of fire. It appears that within the past twenty-five years two conflagrations have occurred at the Vermont Asylum, one at the New York State Asylum at Utica, one at the Kansas State Asylum, whilst the State institutions in Ohio, West Kentucky, Minnesota, and Danville (Penn.) have been almost totally destroyed, and a considerable number of lives lost. The writer, amongst other suggestions, advocates the appointment of a State fire inspector, who should be held responsible for the completeness of the arrangements to meet so terrible an emergency as fire in an establishment devoted to the care of the insane.

Ars celare artem.—We shall consider the question, but there is a great difference between the subjects.

Mr. C. Burland should apply to the Dean of the University for information.

THE NOTIFICATION OF INFECTIOUS DISEASES.—THE JARROW CASE.

To the Editor of THE LANCET.

SIR,—Being defendant in the case tried in the police-court here under the Local Improvement Act, 1878, I trust you will find space for a few remarks in addition to those which have already appeared in your journal.

The Act defines "infectious disease" as meaning small-pox, cholera, and fever, and enacts that the medical practitioner in attendance on such a case shall, under a penalty of five pounds, send to the corporation the name of the patient, &c., and the "nature of the disease."

Whilst bearing in mind the evident intention of the Act, it surely seems more reasonable to consider small-pox, cholera, and fever as intended to indicate the kinds or types of disease to be reported infectious, excluding, for example, whooping-cough, &c., which, although infectious, it was probably deemed unadvisable, in the meantime, to have brought prominently under the notice of the local sanitary authority, than to hold by an interpretation which would exclude diseases equally as infectious and fatal (measles, diphtheria, &c.) as those to be reported. Besides, when a case is reported "infectious disease," its nature is sufficiently indicated to enable the sanitary authority to adopt the precautions necessary. Such a mode of reporting is also a means of preventing a possible mistake in diagnosis from being brought prominently before the Council and the public, and possibly the author of the report from being subjected to injudicious criticism, which might prove injurious to his professional reputation. That such a result is likely may be inferred from the evidence in this case.

Not being permitted to give evidence, my solicitor submitted that it was impossible to report anything but infectious disease, as I had not ascertained its precise nature. In opposition to this, the sanitary medical officer stated on oath that on first seeing the patient he had no difficulty in diagnosing the disease, and that I could not possibly have had any difficulty on the previous day, and, in addition, that he never experienced any difficulty in diagnosing a case.

True, as stated, we are paid for our reports, and some of our councillors say that the interpretation indicated above is contended for, so that a few more diseases may be reportable, and a little more money made by it. After that, the almighty dollar, as a means of influencing men's opinions, must give way to the "bob;" but it will probably be found out by-and-bye that an Act of Parliament, even when backed by a shilling fee for each report, may utterly fail in compelling medical men generally to be saddled with the position of specialist in diagnosis, when a sanitary medical officer is employed for the purpose of supplying such information.

I am, Sir, yours, &c.,

Jarrow-on-Tyne, April 4th, 1881. W. WHAMOND.

Mr. J. Browne.—Our correspondent seems to be labouring under a misapprehension. Officers of the A.M.D. are put in medical charge of native troops when the P.M.O. considers it necessary, but they do not receive less than medical officers of the Indian service employed in this manner, if of the same rank.

Auge.—We fear we cannot promise early insertion of the paper.

"CHRYSOPHANIC ACID IN PSORIASIS."

To the Editor of THE LANCET.

SIR,—I do not think the point raised by a "Glasgow Student" should be lightly passed over, or that anyone should condemn it without testing the effects of chrysophanic acid to the full. I have used chrysophanic acid ointment from five grains to two drachms to the ounce, and have had the good fortune never to have had a case of psoriasis where its beneficial effects were not apparent when directly applied.

In many cases also where I have applied it partially without any application to other affected parts I have been much struck with the disappearance of the disease from the parts to which there had been no direct application; a result I can explain in no other way than by the constitutional effects of chrysophanic acid.

One effect I have noticed on several occasions in the long-continued use of chrysophanic acid is congestion of the conjunctivæ, no matter where the ointment may have been applied, if in sufficient quantity. Is not this a constitutional effect? I would ask the writers in last week's LANCET if there is not a possibility of chrysophanic acid retaining its true qualities when absorbed into the system by inunction, while it may be changed and destroyed by the secretions when taken internally.

I am, Sir, yours, &c.,

Glasgow, April, 1881. ROBERT LEES, M.B.

Croonian Lectures

ON THE

INFLUENCE OF THE CIRCULATION ON THE NERVOUS SYSTEM.

Delivered before the Royal College of Physicians of London,

By WALTER MOXON, M.D. Lond., F.R.C.P.

LECTURE III.—Part I.

Mr. President and Gentlemen,—In my last lecture I endeavoured to show that certain special diseases described in our text-books as congestion of the brain must be referred to other causes, and, indeed, chiefly to conditions the very reverse of a state of congestion. And I gave my reasons for believing that there is not any such disease as congestion of the brain in the sense of determination of blood to the head; or, in other words, congestion, as a cause of onset of attacks of diseases such as are described in some of our leading works under several distinct forms, does not exist. Neither pathological examination of persons dying under such conditions, nor the clinical symptoms described, afford any proof that a congested state of the brain even attends such illness, let alone gives rise to it; and the supposition that the blood causes such symptoms arose from views regarding the cerebral circulation which are obsolete.

Meantime, whilst such obsolete views of the cerebral circulation have entailed upon us the confusing doctrine of congestion of the brain, modern views of the vascular mechanism have in their turn given rise to speculative explanations of nervous disorders, which greatly and increasingly influence present teaching upon diseases of the nervous system. I refer in particular to the widely-spread assumption that epilepsy and other convulsive disorders are caused or initiated by spasm of the arteries of the brain. I will, with your permission, now examine the grounds of such an opinion, and afterwards consider the relation of angina pectoris to high tension in the arteries.

Any explanation is so much better than none that the explaining power of a new view is apt to purchase condonement of its unreality. Only let us with Kussmaul assume that he produced epilepsy in animals by ligaturing all the cervical vessels; and then if, indeed, we can further justly persuade ourselves with him that the arteries of the brain are able to contract universally, through an impulse sent to them along the vaso-motor nerves, so that the brain is rendered entirely anæmic as if the cervical arteries were all ligatured, this would undoubtedly make epilepsy a very comprehensible thing, reducing the whole highly complex set of actions to dependence upon a single impulse from the vaso-motor centres. Even if we don't accept the theory of entire anæmia, but take the same idea as modified by Schrœder, and now taught as the fashionable theory of epilepsy—namely, that the vaso-motor nerve carries forth a contractile influence to the arteries of the brain, which blanches it enough to produce unconsciousness,—we make a step which invades the mystery of epileptic convulsions, and which would put at least a part of it into continuity with the paleness of emotion, and other familiar things of the kind.

If we go further, and suppose with some writers who have devoted special attention to nervous diseases that in an epileptic convulsion the tonic stage is caused by tonic spasm of the arteries, and that each jerk of clonic spasm in the subsequent convulsion is due to a corresponding short spasm of the arteries of the brain, we can read off the epileptic paroxysm in hydraulic changes, and this appears to afford a certain satisfaction which may be taken for an explanation of the subject. Indeed, in the supposed power of rapid and entire closure of all the cerebral arteries, or the supposed power of rapid closure of any of them under the influence of the sympathetic, we have a handy method of unlocking almost any difficulties as to nerve-action, and if you will only imagine that the arteries close or open to the play of sympathetic influence, like mysterious doors in enchanted forests to the utterance of "Open, sesame," many otherwise impenetrable obscurities seem made free to the entry of light.

Now there is no doubt that the arteries, and especially the smaller arteries, are provided with muscular fibres in their walls, and that these muscular fibres contract, and cause the arteries to narrow their channels. But what we have to do with is the degree in which this power of contraction is under the influence of the vaso-motor nerves. If it were really the case that the muscular activity of the arteries is entirely dependent upon the action of the vaso-motor nerves, the powers of these nerves would stand in a much clearer light. But the contractions of the arteries serve purposes with which the nerves have nothing to do, and over which the nerves have no power. For it has been shown that the contractions of the arteries will proceed just the same when the vaso-motor nerves are destroyed. Thus the remarkable rhythmical contractions and dilatations of the arteries in the rabbit's ear are independent of the vaso-motor nerves, for they continue when the cervical sympathetic is divided, and even, according to Professor Michael Foster, when the cervical ganglion is extirpated. Again, Kussmaul relates that after section of the cervical sympathetic nerve he has seen the arteries of the rabbit's ear contract and drive their contents into the veins. Yet no ganglionic mechanism has been found in the rabbit's ear to account for these effects by nervous action. From such facts it follows that the muscles of the arteries possess and exercise their powers in a way independent of the vaso-motor centres, and that their contractions are not organised only to answer to those centres, but that the muscularity of the arteries fulfils functions independently of the play of the vaso-motor nerves upon them. This would lead us to anticipate limits to the power of the vaso-motor nerves over the arteries. And, indeed, if we study the results of the various experiments which have revealed the intricacy of the vascular mechanism, we find some points appearing which are important for our question. The first point is that when arteries are subjected to irritation so as to cause them to contract, the contraction is not instantaneously rapid, but measurably slow; on this point there is a very general agreement among observers. Reid in his "Physiological and Anatomical Researches," p. 46, says, "The contractility of the arteries manifests itself by slow contraction followed by equally slow dilatation." Carpenter (p. 330, ed. 1876) quoting Weber, says, "The electric stimulus is most effectual when applied by the magneto-galvanic apparatus; when the minute arteries of the mesentery of frogs between $\frac{1}{7}$ and $\frac{1}{17}$ of a Paris line in diameter are thus stimulated, they do not immediately respond to the irritation, but begin to contract after a few seconds, so that their diameter in from five to ten seconds is diminished by a third and their sectional area consequently reduced to about half; by a continued application of the stimulus the calibre is so much reduced that only a single row of corpuscles can pass, and at last the vessels become completely closed and the current of blood arrested, the original conditions being restored on the cessation of the electric current." Paget ("Surgical Pathology," p. 225), says, "If as one is watching the movements of blood in a companion artery and vein the point of a fine needle be drawn across them three or four times without apparently injuring them or the membrane over them, they will both presently gradually contract and close . . . . . follows at some interval after the application of the stimulus and is slowly accomplished, it shows that their power of contraction is like that of parts with smooth or organic muscular fibres." Michael Foster says, "By galvanic and still better by mechanical stimulation this muscular coat may in the living artery be made to contract. During this contraction, which has the slow character belonging to the contraction of all plain muscle, the calibre of the vessel is diminished." I have made many observations upon the contraction of arteries as caused by direct stimulation in watching the development of the inflammatory process, and have observed them to contract slowly. I never saw complete contraction in less than six seconds. But I have never witnessed the effects of stimulation of the vaso-motor nerves. It is antecedently improbable that if the contractions of arteries are slow when caused by direct stimuli, they would be rapid under indirect. Dr. Burdon-Sanderson in the "Handbook for the Physiological Laboratory," page 237, when speaking of the direct excitation of the spinal cord by galvanism in the frog, says, "On opening the key for a moment so as to allow the induced current to pass through the needles, it is seen that all the arteries of the web at once contract, the contraction increasing for four or five seconds, and then gradually subsiding; if the excitation is continued for several seconds the circulation stops." I have here a copy of a diagram from Professor Michael Foster's work which is perhaps more to our purpose, as it shows an instance of the rate of arterial contraction in a mammal. It is a manometer trace of the fall of blood pressure caused by galvanising the depressor nerve in the rabbit, but it is said in the text that galvanising the excitor nerve will produce sometimes the exact reverse of this trace. The slow progress of the contraction is evident when we see that it takes thirteen seconds to complete the action, and that this action is nowhere sudden, but is gradual throughout. This corresponds with the usual characters of contractions of plain muscular fibre. My first proposition, then, is that the contraction of arteries is slow, requiring from four or five to thirteen seconds for its completion.

I will next inquire what is the degree of completeness of the contraction of arteries as caused through the vaso-motor nerves. We have seen that the entire closure of the arteries may be caused in the web of the frog's foot by the stimulation of the spinal cord. But it must be observed that in cold-blooded vertebrates the several parts of the vascular system stand in somewhat different relations to those they bear in warm-blooded animals. In fish the veins have pulsatile sacs upon them. The veins as well as the arteries of the frog's foot will close on application of a direct stimulus. Frogs have lymphatic hearts. In short, there is less differentiation of the vascular mechanism in such animals; the heart does less and the vessels more in the work of circulation. If, instead of such remote creatures, we take examples from amongst warm-blooded vertebrates, the development of whose vascular mechanism is more like that which belongs to the human organism, we find that the powers of the vaso-motor nerves are moderate. There appears evidently in the descriptions of the results of the stimulation of the vaso-motor nerves a much less extent of contraction produced than there is of certain and large dilatation of the vessel on section of the nerve. Section of the vaso-motor nerves dilates the arterioles very decidedly, and when the vessels are thus dilated if an interrupted current is sent through the distal segment of nerve, such a current as would tetanise a muscular nerve, the result, according to Professor Michael Foster, is to cause the arteries to contract "to or beyond" their normal calibre. This would lead to the inference that stimulation of the vaso-motor nerves in the most violent way will do little more than counterpoise the effect of total paralysis of the nerve. In one of Ludwig and Cyon's experiments cited by Dr. Burdon-Sanderson, the normal arterial pressure was ninety milimetres; after division of the splanchnic the fall was to forty-one millimetres; during excitation of the peripheral end of the nerve 115 millimetres. Thus the rise on stimulation did not exceed the normal by half the extent of the fall on division of the nerve. In the case of the rabbit's ear, after the vessels have been made very visible by the dilatation of them consequent upon division of the cervical sympathetic, the same authority says, if now the peripheral end of the divided nerve is placed between the copper points and the key opened, the artery contracts and the congestion of the ear disappears. Dr. Michael Foster says a galvanisation of the peripheral end of the nerve will cause the rabbit's ear to become pale, much paler than normal; if the current be strong, the vessels diminish in size, so that the smaller ones disappear and the temperature falls. But, then, it must be remembered that the visibility of the smaller vessels and the rise of temperature were due to total paralysis of the vessels by section of the nerve. And that the galvanism has to close up the vessels dilated by paralysis, and to cause a fall of abnormal temperature. Also the vessels have to be seen through the skin of the ear, and none of them are large, so that the continued visibility of these small vessels covered by skin and hair when under tetanising stimulation of the nerve shows how limited is the power of the vaso-motor nerves over the arteries. Now, these are but moderate results as compared with ligature of the cervical arteries; and if stimulating the arteries by tetanising the vaso-motor nerves only causes them to contract "to or beyond" their normal calibre, and if the muscular powers of the arteries are shown to act independently of the vaso-motor nerves, it is fair to ask, what justification there is in this for supposing that any action of vaso-motor centres will equal Kussmaul and Tenner's proceedings, so that the arteries of the brain may be virtually ligatured by the cervical sympathetic. When the physiologist proceeds from his point of view to apply any conclusions from his experiments to practical medicine, he is very moderate; he has seen the extent of contraction and dilatation obtainable by cutting and galvanising the sympathetic, and he does not suppose that the sympathetic can ligature the cervical arteries. What he says is as follows: "The numerous pathological phenomena classed under sympathetic action, such as the affection of one eye by disease of the other, are probably at the bottom the results of reflex motor-action"; and again: "The afferent impulses may arise anywhere, as, for instance, in the brain. Thus an emotion originating in the cerebrum may either inhibit or exalt that portion of the vaso-motor centre which governs the vascular area of the head and neck, and thus call forth"—what?—"either blushing or pallor." This is very moderate; it corresponds with the degree of change in the calibre of the arteries observed in experiment. But it gives no adequate grounds for any supposition of an action of the vaso-motor centres that would equal Kussmaul and Tenner's ligatures in depriving the brain of blood so as to cause fits of epilepsy, or even fits of unconsciousness. Attempts to produce such fits by galvanising the cervical sympathetic ended in failure. The physiologist only claims for the action of the vaso-motor nerves such effects as blushing and pallor, and these would rather go with fits of laughter or crying. Even in the matter of blushing and pallor we are not entitled to suppose that the change of blood-stream is altogether due to the vaso-motor nerves. It is true, of course, that bad news will make the face pale, but we must not forget that such causes influence the heart's beat, and thus a person suffering a mental shock has his circulation altered at its centre and feels this effect universally; so that, perhaps, his stomach seems to turn, and he may have to go and eat his supper with what appetite he has. In fact, the only changes in the vessels of the face that can be certainly referred to the vaso-motor nerves are such changes as are more properly called flushing, as in the hectic of phthisis, or in the redness of the eye in neuralgia.

There is, of course, not the slightest doubt about the arteries possessing and using the power of contraction. But in estimating the effects of their contractile actions we have to note carefully the rapidity and the degree of their contraction, and the extent to which it is under control of the vaso-motor centres and nerves. It must, I think, be admitted that so far as we have any evidence of sudden and entire closure, the arteries, if they possess such a power, are curiously sparing in the use of it. Indeed, I do not know a single instance in which the arteries put forth a power of sudden and total closure in parts exposed to view. The arteries appear to reserve all these quick and strong acts for exhibition, if I may so speak, in dark séance in such deep parts as are hidden within the cranium. But if the arteries are capable of inducing sudden blanching by total contraction why should the brain be the only part subject to such play? Why should not the arm, or leg, or ear, or nose, now and then, show sudden paleness and redness from central vaso-motor play?

The kinds of instance which show the effect of contraction of the arteries are well-known: thus the waxlike paleness of one or more fingers which some people are subject to, the drying of the mouth through depressing emotion, and its moistening through appetite; the flow of tears; the reddening of one ear "when people are talking of you at a distance." In all these cases we have effects which are, doubtless, due to the power of the nerves over the arteries, and some of which come on tolerably speedily. But in all these and such instances there is moderation in rate of accession, and also moderation in degree of the arterial change.

Let us now proceed to consider the onset of the epileptic convulsion which it is customary to attribute to spasm of the cerebral arteries. I have already traced this theory through Schrœder van der Kolk to the experiments of Kussmaul and Tenner, who produced epileptiform convulsions by ligature of the cervical vessels in rabbits, and who thereupon started a theory that spasms of the cerebral vessels would have the same effect. Schrœder adopted a part only of this theory, supposing that spasms of the cerebral arteries produce the unconsciousness but not the convulsions of epilepsy, and this theory is adopted by our own authorities upon the subject. But if we now refer to the published accounts of Kussmaul's experiments, we shall, I think, see reason in these to conclude that spasm of the arteries will not explain the onset of epilepsy. If we turn to Kussmaul's work we find as follows:—"General convulsions usually followed in from eight to eighteen seconds, after complete withdrawal of arterial blood. . . . We found in every instance that the closing of all the four arteries was necessary to produce rapid convulsions. If but one carotid or one subclavian has remained pervious, we have never seen convulsions take place, even when the ligature has remained on the other three for several hours; the animals, however, have generally appeared enfeebled and more or less paralysed."

It appears, then, that when the arteries were closed absolutely as to three-quarters of their supply, no phenomena of epilepsy occurred, but only enfeebleness. We do not know what proportion of the remaining one-quarter of the arterial supply would have been sufficient to keep off the epileptic attack, since it was necessary to take this one-quarter away at one stroke by ligaturing the one remaining artery. But there were instances in which the fits did not occur even when all the cervical arteries were ligatured, instances which Kussmaul explained by supposing some small artery to have reached the brain from an unusual source. Hence a very small remainder of arterial blood-supply prevents the onset of epileptic phenomena. But I think I have shown from our best accredited works on physiology that the most forcible stimulation of the vaso-motor nerves in mammals is far from causing complete closure of the corresponding vessels, and, although there are no numerical proportions given, yet I submit that the descriptions which I have quoted justify me in saying that it is at least very doubtful whether the arteries can be made to contract down to one-quarter of their natural calibre by any known mode of action of the vaso-motor nerves, whereas it requires a contraction beyond this degree to produce any part of an epilepic attack.

Again, it is not only on account of its insufficient degree that arterial spasm will not explain any epileptiform phenomena, but there is the further lack of quickness in the act of arterial contraction. Let us take into consideration the slow rate of action of the arteries. When we realise the fact that even the partial closure which a vaso-motor nerve can cause in an artery requires from five to thirteen seconds for its production, we shall perceive that arterial contraction is too slow an affair to be credited with the production of the epileptic onset. For consider the frightful suddenness of the epileptic fit and compare it with thirteen or even with five seconds. Let anyone count five seconds on his watch, and he will find it a considerable time. If a person when taken with an epileptic attack had thirteen seconds warning, by changes in his brain through gradual loss of blood-supply, he would have time to do a great deal to protect himself. He could almost come in from the garden into the house, or at any rate cross his room to lie on a couch. Even if he had only five seconds he could get safely down upon the floor. But instead of this they fall downstairs or into the water, or into the fire; a stroke of lightning is not more absolutely sudden. Surely it is not to be supposed that no feeling at all would arise in the brain during a gradual blanching of it up to the degree Kussmaul and Tenner showed to be required before the epileptic onset will appear.

Meantime, however, it remains true that when a person is seized with epilepsy the face becomes very pale, and so some interference with blood-supply evidently does occur. And although I think it is our duty, in forming opinions on these grave subjects, to test the foundations and the reasonableness of our conclusions, yet I should not have spent so much time in showing the groundlessness of the theory of spasm of the cerebral vessels if I could not offer facts of a kind to explain the paleness of the face, and perhaps the unconsciousness of the epileptic seizure.

But I will now relate some observations which have convinced me that the cause of paleness of the face in the epileptic attack is stoppage of the heart's action. The first of these observations was as follows:—Seven years ago I was standing by a patient, who was in bed with cardiac dropsy, in Philip ward, at Guy's Hospital, and I was feeling his pulse carefully; the beats were regular and of moderate strength. I was looking towards the middle of the bed, and my attention was given to the pulse. I missed one, then another beat, and then found the pulse to have stopped so entirely that it made me look up suddenly at the man to see what was the matter. His face had become very pale; his head was turned towards his left shoulder, and the lip and cheek were twitching; the spasms then affected his arms, and he passed into a severe epileptic convulsion. At the time when I first noticed the pulse to disappear the man's arm was quite still. I tried to feel the pulse during the convulsion, but there was so much muscular movement that I could not distinguish it.

I had never before chanced to have my fingers on the pulse at the moment of onset of an epileptic convulsion, nor have I ever done so since until January 13th of the present year, when I was at No. 1 bed, Philip ward, in which bed was a man who had come in with uræmic vomiting and had been seized with convulsions. At the time of my visit he had come out of the insensibility which followed each convulsive attack, and was in an excited state, staring about rather wildly and endeavouring to raise himself in the bed, and calling loudly the word "Beer!" He was not a temperate person. He then lay quite still and looked quietly about him, his arms lying outside the bedclothes. I took his wrist and felt his pulse, it was forcible and regular. I was feeling it when it quite disappeared from under my finger, many beats being missed. I looked at him, he had become very pale in the face, twitching set in, and he at once went into a very severe epileptiform convulsion. Mr. Lane, my house-physician, then told me that he had chanced to be feeling the pulse at the moment of onset of convulsion in the man during the morning of that day, and that the same thing had happened on two occasions in which he had his fingers on the pulse at the moment of the commencement of the attack. Since then Mr. Lane has made a similar observation upon a girl with eclamptic convulsions in Mary ward. So far, however, it might be said that the failure of the pulse was due to spasm of the arteries of the arms. Now, such a sudden universal arterial spasm would be an otherwise unprecedented thing, and my next observation shows that the supposition of it is not wanted. Three years ago I was examining the heart of a young gentleman who was asking my advice on account of attacks of epilepsy. He was standing, and I had my stethoscope over his heart, and was attending to the quality of the sounds. These sounds stopped suddenly, and so completely that in great surprise I moved to look at him, and saw him with exceedingly pale face, evidently quite unconscious, his balance just lost, and he falling forwards. He went forthwith into severe epileptiform convulsions. Dr. Hughlings Jackson has kindly informed me that he has observed on several occasions the pulse to disappear during the paleness of the face in the onset of attacks of petit mal, and Dr. Hilton Fagge was good enough to send me the following notes of a case:—

"John W——, aged twenty three, consulted me for epistaxis. While I was listening to his heart it suddenly stopped beating. His face turned very pale. He said, "I am going to faint," and sat down in the chair from which he had risen that I might examine him: there was of course no pulse at the wrist. Then his face flushed and his pulse started again; I suppose the attack lasted half a minute. There was distinct twitching of the muscles of one or both hands. I could not observe very well, having to get water, and being alarmed at his condition. On recovering he said that he often had "fainting fits," explaining this by adding "when he cut himself badly more than ten years previously he had had epileptic fits."

A medical friend, whose observation I can well trust, and who has a daughter subject to epileptic seizures, with frequent attacks of "petit mal," writes to me that "her heart appears to stop in every attack."[1]

Now, in inquiries amongst my colleagues and friends, these are all the cases I have been able to meet with in which the state of the circulation has been observed at the first moment of the epileptic onset. There are, of course, very numerous observations upon the state of the pulse when the patient has already fallen. The heart's beat has, however, recommenced, as I suppose is necessary if life is to continue. I do not know how many beats can be entirely omitted without death resulting, but the number must be limited, because the circulation depends on tension in the arteries, and the whole arterial tension must be due to but few heartfuls of blood, so that the loss of few beats would take the tension quite away. I would, however, ask your notice of the fact that most observers, who have felt the pulse just after a person has fallen in an epileptic fit, agree in describing the pulse as small, sometimes imperceptible. It is said, in descriptions of the first stage of the fit, to be sometimes unaltered, but I think this must refer to the later part of the first stage during which the pulse recovers itself, but the insensibility continues. I have found the pulse present again when the clonic spasms have just commenced. The observations which I have adduced showing failure of the pulse in the first onset of epileptic attacks tend to take away the significance of a very wonderful case which is quoted by Kussmaul from Pereira as some evidence of spasmodic closure of the cerebral vessels. In this case the pulse at one wrist was observed to disappear in the onset of an epileptic attack, and the post-mortem examination showed that the radial artery received its supply through the vertebral from the circle of Willis, a very remarkable anomaly indeed. It is inferred by Kussmaul that in this person the arteries of the brain went into spasm, and the spasm shut off also the blood from the arm, which had the misfortune to derive its supply from so irritable a source. But I think it is reasonable to conclude that in this very wonderful case, what really happened was a failure of the heart's action as in my cases.

---

[1] At the conclusion of the lecture Dr. Southey informed me that in the only instance in which he had his finger on the pulse at the beginning of an epileptic convulsion he observed the pulse to disappear during the onset of the attack.

Thus, so far as I have been able to learn, the unconsciousness in an epileptic fit is of just the same nature as the unconsciousness in a fainting fit. It has happened to me, as, I presume, to most physicians, to be able to notice the first onset of a fainting fit. Time will not allow me to describe the several occurrences, but in one young candidate for service at a bank, who fainted under examination, the heart's beat ceased as I was listening, and the lad fainted. He was pale throughout the attack, and he retched as he was recovering, and told me that nothing of the kind had ever happened to him before. In the case of a young lady subject to "fainting fits" I observed that the heart stopped beating; she used to fall very suddenly, and slight twitching of the face appeared, nothing more like epilepsy ever occurred, but such attacks are very like epilepsy, and I think that sudden faintings are always to be regarded with suspicion when they take place without sufficient cause of the nature of violent emotion or shock from some horrifying occurrence. Practically the presence of adequate cause of this kind is the readiest distinguishing character of what one might call normal faintness as contrasted with epileptiform fainting; other distinctions lie in the more sudden onset, and the earlier return of colour in epileptiform fainting. These sudden fits of unconsciousness occurring without shock to explain them appear to bear the same relation to the "petit mal" of epilepsy as eclamptic convulsion bear to the "haut mal." I mean that in either of the two parallels the character of the attacks is the same, and the difference is due to the cause of the attack which in fainting, as in eclampsia, is temporary; but in "petit mal," as in epilepsy, tends to produce a recurrence of the attacks. I do not know how the cessation of the heart's action is caused, but I suppose it is through the pneumogastric nerve. It is quite certain that this nerve is capable of inhibiting, as it is called, the heart's action so as to stop it for many beats. So that the power of the pneumogastric to cause the change is beyond question. Whereas I have shown that there is great reason to doubt that spasm of arteries will stop the circulation in the brain so as to produce insensibility. Another fact that points to the pneumogastric as the probable cause of the change is that the gastric branches of this nerve are evidently involved in minor degrees of the condition of fainting. As in the long ago experience of many of us, when the witnessing of sanguinary operations before we were ascustomed to such scenes, induced nausea and sinking sensations more or less embarrassing.

Again, Mr. Tom Bird, whose experience in the administration of anæsthetics is very large, and whose care as an observer is well known, tells me that during chloroform exhibition sudden pallor is accompanied by slowing of the pulse, and followed by sickness or retching. Such lesser degrees of faintness evidently refer to a change of action in the pneumogastric system of nerves. Now it is well known that one of the most common of the immediate causes of sudden fainting fits is the sight of blood, or rather of bleeding. And this sudden fainting, which in those who fall at the sight of a cut finger is abnormal, is an extreme example of a depressing action of the pneumogastric nerve, which is in a lesser degree so far natural that a large proportion of young men suffer a feeling like sea-sickness when first they witness a protracted sanguinary cutting operation. So that the blanching and insensibility of the epileptic onset may be reasonably regarded as an effect of pneumogastric inhibition, the initial step being thus an act of the nervous ganglia.

And, indeed, it must be clearly seen that any explanation of the epileptic seizure thus comes ultimately back not to the hydraulic mechanisms of the circulation, but to the seats of origin of the nervous power, in whose endowments lie the mechanism of epileptic convulsion, and in whose action the first impulse must originate when the fit is brought about. But in the cases I have described the next step following this incomprehensible impulse is a very comprehensible stoppage of the heart, with the result of a very comprehensible paleness and insensibility. It is said that paleness does not always occur in the onset of epilepsy. I have observed a livid appearance in the onset of the fit in a very red-faced person. The natural red appearance is, I believe, never retained. There is now under my care an epileptic girl, who also has an extreme degree of inveterate psoriasis, through which her face is reddened intensely with inflammation, yet in the onset of her fits this girl's face becomes very pale.

Starting, then, with a pneumogastric impulse of unknown origin we can, through the cessation of the heart's beat, abundantly satisfy any desire for a hydraulic explanation of the unconsciousness. But we must note that the entirely unknown source of the pneumogastric impulse stands behind our explanation, throwing on it the doubt whether the same unknown impulse which discharges the pneumogastric may not play among the centres where consciousness is seated, and itself involve a loss of consciousness. But, admitting this necessary doubt, we are able to say that the stoppage of the heart's action is itself sufficient to produce the unconsciousness and pallor, so that it is not necessary for us to seek any other explanation of them; and even in the minor degrees of epilepsy, in which there is only a momentary hesitation, as if a blank were suddenly introduced in the continuity of the person's course of action, the stoppage of the heart's beat will explain it, especially as a sense of giddiness accompanies the smallest degrees of such attacks as in epileptic vertigo. For giddiness is, when certainly referable to any change of circulation in the brain, always referable to a diminution of force of the circulation. It very commonly occurs on sudden removal of stress or tension from the venous circulation in the brain, as instanced in the giddiness which is felt on going out of chambers of compressed air, or on rising suddenly from a stooping posture. Very violent giddiness has other and different causes. The extreme giddiness one sometimes meets with, as when a gentleman came to me and begged relief from a giddy attack so violent that when seized he had to call to his daughters to hold him on the floor as he seemed to be falling upon the ceiling. This man's attacks ceased on the occurrence of a paroxysm of gout. Menière's disease offers a frequently applicable explanation of severe giddiness. But there is ample evidence to show that slight giddiness occurs through slight blanching of the brain. So that when in an epileptic subject the face grows suddenly pale, and at the same moment a sense of giddiness is felt, it is reasonable to ascribe all this to failure of the heart, if we have reason to know that the heart fails, and I have endeavoured to show reason to think so. But a fully developed epileptic attack offers us at least three quite distinct occurrences. The first is the initial loss of consciousness, the second the outbreak of convulsions, and the third the state of stupor which succeeds to these. It is a natural and fair question to ask, Will the hydraulic explanation, which suffices for the loss of consciousness, go further and explain the other two terms of the series of events that compose an epileptic fit? Now, either of the three portions of the complete attack may occur almost alone, or, perhaps, quite alone.

In the so-called "petit mal" a partial faint and momentary loss of consciousness are all that happen. In some cases of convulsions a partial degree of epileptiform muscular jactitation is similarly present, and Dr. Hughlings Jackson's name will always be honourably identified with our best thought and knowledge upon this most interesting phase of epilepsy. In other cases the stage of stupor may come on with little evidence of faint or of convulsions, and I think Trousseau has claim to be honourably held in recollection on account of the clearness with which we showed the truly epileptic nature of attacks of this kind, which were, and indeed by some still are, obscured under the designation of apoplectiform cerebral congestion.

This separate occurrence of the three distinct parts of the epileptic attack proves that there is no direct dependence the one upon the other, and yet they are so constantly found united in serial order in the complete epileptic fit that it is natural to look for some causative connexion between them and to find some way of showing how upon the profound fainting attack convulsions would ensue, and how upon convulsions stupor would follow. If this were positively desirable it would not be difficult to bring in Kussmaul's convulsions from anæmia to explain the onset of the spasmodic movements; for if indeed it be a law of the vertebrate organism that a discharge in convulsion occurs when bloodlessness is on the point of becoming fatal to the life of the brain, then a prolonged stoppage of the heart would fall under such law, and convulsions be the result. Nay, we may further here observe that in a certain degree there is in such a law that kind of adaptation to purpose which it is so great a satisfaction to perceive, seeing that when the heart's beat stops the arteries empty themselves, and then tension is done away, and it requires at least six or seven heartfuls of blood to restore arterial tension; meantime, with the removal of arterial tension, the *vis a tergo* on the whole circulation is lost, and the blood is no longer pushed round in a continuous course, so that it would therefore tend to stop in the veins, and in the abdominal veins alone there is room for the whole of the blood; therefore, with all the blood in the veins, and with no *vis a tergo* to act on them, where should the heart get its six or seven charges of blood to start arterial tension once more? But the veins of the limbs have valves that prevent reflux of the blood, and convulsions compress the veins, and drive to the heart the necessary amount to keep the arteries full.

And, indeed, it is quite probable that this is the purpose or use of the convulsions. Neither does it gainsay such a use that the convulsions become extreme and pass beyond the service for which they are adopted. For take the parallel case of the plainly conservative spasm of a cough whose object is beyond doubt to expel undesirable contents from the windpipe; do we not find cough sometimes so vigorously acting in excess of its duties that we are at our wits' end to find some means of keeping this otherwise beneficent contrivance within due bounds? Likewise also, if we ask why stupor should succeed to convulsions, we may think this, too, a natural consequence of the convulsions, and we may also perceive that it favours recovery. For convulsion is no mere exertion, as in healthy exercise; but it is the exertion of otherwise dying nervous centres called out not by the wholesome influence of sufficient or redundant supply, but brought to pass by desperate starvation, and therefore in the matter of exhaustion not to be put on a par with normal fatigue. Then what more likely than extreme exhaustion, and what better than a short deep sleep in which the senses are, if I may so speak, closed for repairs? An insensibility which is thus negative and whose service is plainly to allow time for the centres to recover themselves, is not of itself to be dreaded nor thought of as a terrible thing. It need not be set down to any overpowering positive cause on the baseless old-fashioned theory of congestion of the brain. But here too, in a more dangerous way, we may find ourselves troubled with an excess of what is designed for good, and just as cough may need checking, and as convulsions may prove extreme, so stupor may be protracted, and the sleep which was intended to refresh may not restore excitability, but become longer and deeper, until the person dies in a state of coma. And the normal stupor of the epileptic attack becomes thus extreme and fatal under conditions that sufficiently explain the occurrence. For such fatal coma never happens in the epilepsy of young or vigorous subjects when the brain is well nourished and capable of quick recovery. It is in old age that it occurs, or at the close of a long course of cerebral exhaustion, especially when an impure state of the blood adds another cause of stupor, as in cases of protracted jaundice, or diabetes, or chronic renal disease, which not unfrequently terminate by a sudden epileptiform coma or in old alcoholism in unstable brains. In these cases essentially epileptic attacks occur in which there is little or no convulsion and the person appears seized with sudden coma. But as a proof of the epileptic nature of such attacks it is remarkable that in the description of them under the erroneous title of "apoplectiform cerebral congestion" it is stated that the pulse disappears at the wrist in the onset. Now, after the cases which I have given I consider this to be evidence of the epileptic nature of these attacks. For clinical evidence of the connexion of such attacks in individual cases with the history of epilepsy I have already referred to Trousseau's lecture on the subject. But if I had time I could give many cases of the kind from my own experience.

CHRYSOPHANIC ACID AND PSORIASIS.

By M. CHARTERIS, M.D.,
PROFESSOR OF THERAPEUTICS AND MATERIA MEDICA, GLASGOW UNIVERSITY, AND PHYSICIAN TO THE GLASGOW ROYAL INFIRMARY.

THE circumstances under which I was induced to try chrysophanic acid, as indicated by the correspondence in your journal, briefly stated, are as follows:—

A boy of nine years of age was admitted into my wards on April 5th last, covered, as the ward journal states, "with a scaly eruption, which came on about three years ago, and gradually extended until it embraced the whole body, being, however, most marked and patchy at the outside of the knees and elbows." He was ordered to be rubbed with the chrysophanic acid ointment (one drachm to one ounce of vaseline), and four days afterwards the nurse informed me that he had been sick and had vomited. On inquiring a little further into the matter, I made the remark to my clinical class, "I wonder if the application of the acid could have done this," and I stated "that I would on a subsequent occasion test the ointment with a view to elucidating the truth." Meanwhile I discontinued to employ the acid to the boy in the same strength, making the proportion half a drachm to the ounce; and he was dismissed well on May 3rd, without any further untoward symptoms. In accordance with the view suggested, the next patient admitted into the male wards was only rubbed with the acid of the same strength on one side of the body—the other being untouched. Both sides healed, but some dubiety existed on my mind, and also on that of my assistant, as to the truthfulness of the patient's statement, for we suspected, in his anxiety to become well, he had surreptitiously applied it to both sides. In the case also during the same summer of a female patient, we were suspicious that the nurse, somewhat inexperienced and zealous, had occasionally and intentionally forgotten the directions given and used it on places we had warned her to avoid. In publishing my clinical retrospect in THE LANCET of last autumn, I alluded to this, and said with regard to the chrysophanic acid ointment: "A singular circumstance was noted—viz., that the acid rubbed in must have some constitutional action, for if applied only to one side of the body it seems eventually, though more slowly, to remove the scales from the other. This observation, though true in one case, was not so marked in another, and would require further verification."

Continuing my narrative, I may state that the next case of psoriasis was admitted on Nov. 18th, 1880. This man, aged twenty-two, had twice before been under treatment in the infirmary for the same complaint, and on both occasions had been treated by arsenic with the result that in six weeks he had left the wards well. The last admission was in 1875, and he stated that since then the eruption had appeared every autumn, but not to any great extent. Six months ago it was very apparent on the elbows and knees, and since then it had spread to the arms and legs, and, as noted now, it is said to extend from the arms and legs over the whole body.

On the 21st Nov. (three days after admission):—One arm and leg were ordered to be covered with close-fitting flannel, and the ointment of the strength previously mentioned to be rubbed in over the exposed parts. On the 1st Dec. the ointment was rubbed in for the last time, and twenty-four hours afterwards a bath was given. On the 6th December it is noted "that the skin on both sides is now clean and smooth, and the patient was dismissed 'cured.'"

In the next case, that of a female aged seventeen, the history and appearance were as follows:—"She had been under treatment three years previously, and had been treated successfully by me with chrysophanic acid. Six months ago the disease appeared again, and at present psoriasis spots are observed on the chest and back, circumscribed and not very numerous. But over the extensor surface of the arm there are large silvery patches, and on the outside of the knees and front of the legs and thighs the eruption is very marked." Stringent precautions were taken in this case to guard against any error in the one-sided application of the ointment, flannel padded with cotton-wool was applied from the upper part of the thigh to the ankle, and secured by tapes so that the ointment could in no way affect it. Two days after admission treatment was commenced by rubbing in the ointment to all the other parts implicated. This "rubbing in" was continued daily for ten days. The nurse used her hand, not a cloth. Fully two ounces were so used every day for four days, until the scales were thoroughly removed, after that about one ounce only of the ointment was applied. Ten days after the commencement of treatment it was found, on taking off the bandages, that the scales had commenced to disappear, the disappearance being most evident at the circumference. On the centres of the patches a few scales were still observed. The skin was left on the previously scaly surface white and clean. A week later the parts rubbed were completely free from scales, and the parts covered very nearly so, with the exception of one or two spots about the size of a pin head, which were situated on the centre of the previously scaly patch. The patient was ordered a bath, and a small bread and water poultice was applied over the previously covered leg. Three poultices in all were so applied on three successive days, and it was found after that time the skin was left clean and whole, and not discoloured as the other side was by the application of the ointment. In this condition the patient was shown to my class at the university, and I have no doubt they will testify to the appearance mentioned. I may add that the patient remained in the ward after this for a month, but the eruption did not reappear. The total quantity of ointment used in this case on twenty-four applications was thirty-two ounces, of the strength of one drachm to the ounce of lard.

It will be observed from the history of these cases—1. That the ointment was applied with no stinted hand, but, as the nurse states, rubbed in until it had been all absorbed. 2. That the strength of the ointment was perhaps stronger than that generally used—viz , one drachm to the ounce. 3. I venture on no speculation as to how chrysophanic acid may act if given internally. I simply state careful, well-recorded facts with regard to the influence of its one-sided application, and these facts can be corroborated without reservation by many who watched with interest the progress of the experiments.

Glasgow.

ON WOUNDS OF THE KNEE-JOINT.[1]

By WALTER RIVINGTON, F.R.C.S. Eng.,

SURGEON TO THE LONDON HOSPITAL.

THE object of this communication is essentially practical. Discarding all theory, setting aside all questions concerning germs and bacteria, I am desirous of contrasting the results of wounds of the knee-joint treated according to the rules of Listerism with those obtained under other methods of dressing, and of eliciting experience on both sides of the question. The records of cases occurring before the introduction of strict antiseptic precautions will be especially valuable. As I purpose confining my remarks mainly within the range of my own observation, it will, I think, be most convenient to relate at the outset the most recent example of wound of the knee-joint which has occurred in my practice, and to make it the text of my paper.

The subject of the injury was one Edward G——, forty-six years of age, a cab-proprietor. On the 19th of May, being the worse for liquor, he fell or was thrown from the box of his cab. From alcoholic causes he was unable to give any positive account of what happened, but he was inclined to think that the wheel of the cab passed over him. He was admitted during the evening of the 19th, with a jagged wound over the right patella about the size of a shilling, and looking to the superficial eye as if it were merely a graze of the skin. My house-surgeon, Mr. Lawton, however, found an aperture at the upper part of the wound from which some serous fluid issued. This aperture admitted a probe, and, with some difficulty, the track of a sinus was found leading upwards and outwards for a couple of inches. There was no other injury anywhere. The patient was sent to bed, and an ice-bag was applied to the knee. The following afternoon he was seen by myself. The knee-joint was swollen, looked inflamed, and was considerably hotter to the touch than the corresponding joint on the left side. The natural outlines of the joint were obscured, fluid inside the joint distending it so as to obliterate the hollows which are observable in the normal condition by the side of the patella and its ligament. Some pus could be pressed out of the small aperture at the upper part of the wound. Having heard Mr. Lawton's account of his exploration with the probe, and of the free escape of serous fluid the day before, and having regard to the distended condition of the joint, I thought that it would be advisable to slit up the sinus, and ascertain the condition of the parts beneath the skin. Thinking it probable that there might be a wound of the joint, I procured a steam-spray producer and allowed it to play upon the wound for a few minutes. A director was then introduced into the sinus, and the sinus was laid open. This done, there appeared a jagged hole in the quadriceps extensor tendon above the patella, and through this lacerated foramen I introduced my carbolised finger behind the patella into the knee-joint, and explored the interior. Then I pressed out of the joint a considerable quantity of turbid serous fluid, almost purulent, and injected into it three or four large syringefuls of a solution of carbolic acid (1 in 19). Finally the joint was emptied as far as possible of all fluid, a drainage-tube passed into it behind the patella, and the wound dressed in the usual manner with protective and gauze. A back splint was fixed to the limb. On the 21st the patient complained of a good deal of pain in the knee, and experienced a sinking feeling due to the deprivation of his customary stimulants. The record for the 22nd says—"The patient is much better this morning; has slept well; the knee is much easier." Temperature: morning 101·6°; evening 101·4°. On Sunday evening, the 23rd, I redressed the wound and withdrew the drainage-tube. There was very little discharge. The temperature continued high for a day or two, being 103° on the evening of the 24th and 102° on the 25th, but the patient remained remarkably well and amused himself with reading during the day. Occasionally he had some painful twinges, but there was no constitutional disturbance or swelling of the limb, and he took all his fluid diet with relish. The wound pursued a perfectly normal course, gradually cleaning and granulating healthily, and as soon as some of the tendinous fibres which had been damaged had come away the aperture leading into the joint entirely closed. It is noted that the temperature on the 19th was up to 103°, and on the 21st and 24th to 101°, but there was nothing to account for this record, and the only way in which I can explain it is by supposing that it was due to the absorption of the effusion in and around the joint. The patient remained some weeks in the hospital, as cicatrisation of the superficial wound was slow. He left in July to return to his occupation, sooner than I wished him to do, and before the joint had regained its freedom of movement. When I saw him in August he was walking about, and stated that the stiffness was passing away. A fortnight ago he came to see me at the hospital in excellent health, with a freely movable joint, and in a most grateful frame of mind.

Now whether we are or are not disposed to assign the favourable issue in this case to the Listerian method, it will be admitted that the result is highly satisfactory, and invites us to apply the method without reserve to any wounds of joints which may present themselves in the clinic. Although well aware that "one swallow does not make a summer," I am strongly inclined myself to attribute the freedom from constitutional disturbance and the preservation of a serviceable joint, without the previous exhibition of violent local inflammation and its effects, to the adoption of the carbolic acid treatment, and I am influenced by several considerations, which I will state as briefly as possible. They are considerations arising out of the case itself, out of the experience of surgeons prior to the adoption of the Listerian system, and out of the experience of surgeons who have carried out that system in its integrity. If we regard the case itself we find that the joint had already begun to inflame, and that suppuration was imminent at the time the treatment was commenced. The surface over the joint was hot and tender, and the joint itself contained a considerable quantity of turbid serum. Supposing, under these circumstances, with a burrowing passage leading to bruised tissues destined to slough, and communicating on the one side with the air, and on the other with the cavity of the joint distended with a fluid capable of putrefaction, I had left the case to the *vis medicatrix naturæ*, aided only by rest on a splint, evaporating lotions, and ice-bags, is it reasonable to believe that as good a progress and result would have been recorded? Or supposing that, without going to the extreme of the spray and gauze, I had thought it advisable to assist the *vis medicatrix naturæ* a little further, and had slit up the sinus, had passed my cleansed finger into the joint, nd inserted a clean drainage-tube of any kind after ressing the serum out of the cavity of the joint, r had adopted the same treatment without the drainage-ube again, supplemented with splint, and lotions, and ice-ags, or plaster-of-Paris casing commended by Billroth, vould the patient have enjoyed a similar immunity from nflammation of the joint, suppuration, abscesses, swelling f the limb, and constitutional disturbance? Before nswering the question bear in mind that the patient was y no means the kind of subject a surgeon would be inclined o select for an experimental wound of the knee-joint to be reated without the most efficient antiseptic precautions, aving probably from his youth upwards been accustomed to pply hot and rebellious liquors to his blood. Neither was he wound the most favourable kind of wound, for it was ot a clean incision, but a contused and lacerated wound. t was not at the most dependent part of the joint, favouring ree escape of effusions, but at the upper part, well adapted or allowing putrefactive changes to spread from the surface o the interior, and run riot in the recesses of the cavity.

---

[1] A paper read before the West Kent Medico-Chirurgical and Hunterian Societies

Such considerations tend to negative anticipations of a very avourable course and issue to the case if it had been treated merely in accordance with what used to be termed the general principles of surgery. And are not these doubts strengthened by recalling the experience of surgeons before Mr. Lister's doctrines and demonstrations had taken root in London and other great centres of the industrial population? Exclude from consideration, for obvious reasons, the results obtained in the perfectly pure atmosphere of country districts. Every one knows that severe injuries and operations, undergone by healthy persons in an atmosphere free from germs and organic impurities, and treated by the simplest means, may be attended with results which can scarcely be surpassed by the best records offered to us by the disciples of Mr. Lister. My friend Mr. William Forbes, who was house-surgeon at the London Hospital when I was one of the dressers, and who is practising at Sale in Australia, told me not long ago that there was no comparison between the results which he used to witness at the London Hospital and those which he has obtained in his own hospital in serious injuries to limbs and joints. Hence we may fairly set aside experience of this kind, and compare only the results obtained with and without complete antiseptic precautions in the loaded atmosphere of great cities and hospitals. I say complete antiseptic precautions, because, as antisepticism has become fashionable, everyone now professes to treat his cases antiseptically, whether regard be paid only to rest, pressure, and drainage, or some antiseptic application be superadded—cotton-wool, tenax, spirit and lead lotion, tincture of iodine, friar's balsam, thymol, carbolic acid, and the rest.

Now, I believe that the results obtained, say twenty years ago, by surgeons practising only according to the then recognised "general principles of surgery" in cases of wounds of the knee-joint, were very unsatisfactory. For proof of this it is only necessary to recall the grave apprehension with which surgeons of the old school regarded wounds of the knee, whether inflicted by accident or for any purpose by the design of the surgeon himself. A candidate who presented himself for examination at a college or university, and averred that he might be induced to entertain the notion of laying open the knee-joint, would with tolerable certainty have stood an excellent chance of reference to his studies, and at least would have damaged his prospects of a good position in a competition for honours. Refer to works on surgery, which treat of the natural issue of wounds of joints, and especially of the knee-joint, and it will be seen that among ordinary sequences are numbered profound constitutional disturbance, high fever, delirium, great and constant pain, free suppuration, and œdema of the limb necessitating liberal incisions, pulpy degeneration of the synovial membrane, disorganisation of the joint followed either by anchylosis or excision, or amputation, and that under these conditions the life of the patient may be put in peril. Sporadically, now and then, might be met with a triumphant case—a clean incision carefully adjusted, a puncture sealed with collodion, aided by rest and cold, closing kindly without damage to the joint or serious constitutional irritation. To such cases may be added those in which a knee-joint already full of pus has been saved by free lateral incisions. But however successful may have been the treatment of some surgeons who have "refused to listen to the voice of the charmer," there has always been a reverse side to the picture.

(To be concluded.)

ON TRICUSPID STENOSIS.

By BEDFORD FENWICK, M.D.

Disease of the tricuspid valves, and especially disease in the form of stenosis, is rarely found. Most authors tacitly acknowledge this by making no mention of its existence. A few specialists give the subject a cursory consideration, and chiefly confine themselves to narrating one or two cases, or enunciating one or two dicta. Firstly, say these, the disease is very rare. For example, Dr. Flint[1] writes: "A direct tricuspid murmur is one of the rare curiosities of medical experience," and Niemeyer[2] remarks that "tricuspid stenosis is extraordinarily rare." Secondly, that it is of congenital origin. Dr. Peacock in his classical Lectures on Valvular Diseases (page 24) refers at length to this theory, and in another place[3] he remarked: "It has been subject of discussion whether these cases are the result of disease before or after birth. I am inclined to believe the former to be the correct view." Rosenstein[4] prefaces a short description, probably taken from Dr. Hayden's work, by saying, "when it does occur it dates from fœtal life."

Finally, two authors, and as far as I can learn only two authors, have hitherto collected cases of this disease. Dr. Hayden of Dublin, in his most elaborate work on Diseases of the Heart, quotes twelve cases. M. Duroziez of Paris collated fourteen cases. His main deductions, however, are that the disease chiefly affects the female sex, and that it is not uncommonly found.

Since the year 1825 there have been at least forty-three cases of this affection recorded in European and American literature. I will briefly narrate the particulars of three others, two of which died last year in the wards of the London Hospital.

Therefore, to commence with, I think it may be allowed that the disease is not "extraordinarily rare." Probably, if this fact becomes recognised it will be more carefully looked for, and more often discovered than hitherto.

The total forty-six cases are summarised in the appended Table (No. 1), and by merely analysing these, I hope to exhibit the salient features, clinical and pathological, of the disease, and by their facts to test the validity of the congenital origin theory.

Case 1. (No. 43 in Table I.)—A. C——, a married woman, aged twenty-four, was admitted into the London Hospital under the care of Dr. Down, at the end of the year 1874. Her previous history showed that she had enjoyed good health till the age of nineteen. She then suffered from an attack of acute rheumatism, from which, however, she recovered well and quickly, and then continued in her usual state of health for three years. She was then attacked again with rheumatic fever, and from that time suffered from dyspnœa on exertion and palpitation. On admission there were great general œdema and ascites, orthopnœa, severe and irritable cough, and great lividity. The point of cardiac impulse was visible between the seventh and eighth ribs, and one inch external to the nipple line. The area of dulness was laterally increased. The heart's action was occasionally tumultuous, always irregular. There was a loud presystolic murmur audible at the apex; systolic and diastolic murmurs at the base. The jugular veins were much distended, the urine scanty, the temperature subnormal, the pulse small and irregular. She gradually sank and died comatose.

On post-mortem the heart was found to weigh 22 oz. The tricuspid valves were much thickened and roughened, and the orifice only admitted three fingers. The right auricle was enormously dilated, measuring $3\frac{1}{2}$ inches by 4 inches. The mitral valves were greatly thickened and contracted, the orifice barely admitted three fingers. The aortic valves were thickened and incompetent. All the organs of the body were in a state of chronic congestion.

Case 2. (No. 44 in Table I.)—E. C——, an unmarried female aged twenty-nine, a domestic servant, was admitted into the London Hospital in February, 1880, under the care of Dr. Samuel Fenwick. Her previous history was very

TABLE I.

No.	SEX.	AGE.	PREVIOUS HISTORY.	SIZE OF TRICUSPID ORIFICE.	SIZE OF MITRAL ORIFICE.	CONCURRENT CARDIAC CHANGES.
1	M.	37	One attack of acute rheumatism at 15 years old.	Barely admitting two small fingers.	Contracted to a like extent.	Aortic valves much thickened. Ventricles much hypertrophied. Auricles dilated and hypertrophied.
2	F.	42	No rheumatic history.	Admitting the middle finger.	Admitting only the point of the little finger.	Great dilatation of the right auricle. Dilatation with hypertrophy of the right ventricle.
3	F.	37	No rheumatic history.	Only admitted one finger.	Only admitted one finger.	Aortic valves disorganised and incompetent. Dilatation and hypertrophy of all cavities, especially the right auricle.
4	F.	37	No rheumatic history.	⅝ in. by ⅜ in. in diameter; 21 lines in circumference.	3-5ths by ¼ in. in diameter; less than 2 in. in circumference.	Right auricle aneurismal, measuring 3 in. by 2 in. Aortic orifice thickened, only measuring 3 in. in circumference.
5	F.	20	No rheumatic history.	7 by 6 lines in diameter.	5 by 5 lines in diameter.	Dilatation and hypertrophy of all cavities, especially the right auricle. Aortic valves diseased.
6	F.	23	Not noted.	Only admitting the point of the index finger.	Contracted to an equal extent.	Right auricle much dilated and hypertrophied. Aortic valves incompetent.
7	M.	35	Acute rheumatism 6 years previously.	Only admitting the forefinger beyond the first joint.	Admitted the tips of the two first fingers.	Right auricle greatly dilated.
8	F.	26	No rheumatic history except pains.	Only admitting the tips of two fingers.	Only admitting the point of the index finger.	Right auricle normal. Left auricle greatly dilated. Aortic valves much contracted.
9	F.	26	Acute rheumatism 14 months previously.	Only admitting the tip of the index finger.	Only admitting the tip of the little finger.	Right auricle greatly dilated. Left auricle also dilated.
10	F.	young	Not noted.	Only admitting one finger.	Only admitting the end of the little finger.	Both auricles dilated, especially the right.
11	M.	23	Acute rheumatism at 9 and at 13 years old.	Only admitting the tip of the middle finger.	Only admitting the tip of the index finger.	Right and left auricles much dilated.
12	F.	27	Acute rheumatism 6 years previously.	Only admitting the index finger.	Only admitting the point of the little finger.	Right auricle much dilated.
13	F.	25	No rheumatic history; measles very badly at 16 years.	Only admitting the point of the middle finger.	Only the point of the index finger could pass.	Both auricles, especially the right, much dilated.
14	F.	38	Three attacks of acute rheumatism.	Not admitting the points of two fingers.	Admitting only the forefinger.	Right auricle greatly dilated.
15	F.	30	Acute rheumatism at 12 and at 24 years old.	Only admitting the point of the forefinger.	Only admitting the point of the little finger.	Right auricle excessively dilated. Aortic orifice as small as mitral.
16	F.	33	With a history of rheumatism.	Only allowing one finger to pass.	¼ in. long by ⅛ in. wide.	Right auricle much dilated.
17	F.	21	Acute rheumatism at 13 and at 19 years old.	Contracted to a narrow crescentic slit.	As tricuspid, but to a greater degree.	Pericardium adherent. Aortic valves rigid and thickened.
18	F.	19	No rheumatic history.	Contracted, rigid, and in places ossified.	Sufficient to admit the tip of the little finger.	Not noted.
19	F.	22	No rheumatic history.	Considerably contracted.	Considerably contracted.	Aortic valves much thickened and considerably contracted.
20	F.	32	Acute rheumatism at 19 and at 30 years of age.	Having a circumference of about fifteen lines.	Similarly contracted.	Aortic valves thickened and incompetent.
21	F.	18	Acute rheumatism 18 months previously.	Much contracted.	Exceedingly contracted.	All the cavities dilated and hypertrophied.
22	M.	21	One attack of acute rheumatism.	Admitted two fingers.	Admitted two fingers.	All cavities, especially the right auricle, greatly dilated.
23	F.	44	One attack of acute rheumatism.	Admitted two fingers.	Only admitted the end of the little finger.	Aortic orifice insufficient.
24	F.	46	No rheumatic history.	Admitted two fingers.	Only admitted one finger.	Aortic orifice stenosed and incompetent.
25	F.	37	No rheumatic history.	Admitted two fingers.	Only admitted the little finger.	Aortic valves slightly incompetent.
26	F.	40	One attack of acute rheumatism.	Only admitted one finger.	Only allowed a large quill to pass.	Aortic orifice contracted and incompetent. Left auricle dilated.
27	F.	58	No rheumatic history.	Admitting one finger.	Admitting one finger.	Aortic valves incompetent.
28	F.	27	Repeated rheumatic pains.	Only admitting the point of the index finger.	Not quite so small as the tricuspid.	Not noted.
29	F.	36	No rheumatic history.	Only admitting one finger.	Hardly admitting the end of the little finger.	Aortic orifice much contracted.

TABLE I.—(*Continued.*)

	SEX.	AGE.	PREVIOUS HISTORY.	SIZE OF TRICUSPID ORIFICE.	SIZE OF MITRAL ORIFICE.	CONCURRENT CARDIAC CHANGES.
30	M.	64	Repeated rheumatic pains.	Only admitted one finger.	Only admitted one finger.	Not noted.
31	F.	29	No rheumatic history.	Admitted two fingers to the first joint.	Only admitted the end of the index finger.	Right auricle greatly dilated.
32	F.	30	Several attacks of acute rheumatism.	Only admitted one finger.	Only admitted a quill.	Not noted.
33	F.	34	No rheumatic history.	Very considerable contraction.	Very considerable contraction.	Aortic orifice stenosed. Heart hypertrophied.
34	F.	23	No rheumatic history.	Very pronounced contraction.	As the tricuspid.	Aortic orifice thickened and contracted.
35	F.	21	History of acute rheumatism.	Only admitted one finger.	Greatly contracted.	Aortic valves incompetent.
36	F.	43	No rheumatic history.	Nearly 1 in. in length and ½ in. in width, of a half-moon shape.	About ⅔ in. by ¼ in.	Right auricle somewhat dilated. Left auricle enormously dilated.
37	F.	42	No rheumatic history.	Just admitting the little finger.	Not admitting the end of the little finger.	Right auricle considerably dilated and hypertrophied.
38	F.	37	Acute rheumatism at 21 and at 26 years of age.	⅞ in. in diameter.	⅜ in. in diameter.	Right auricle considerably dilated.
39	F.	37	No rheumatic history.	Stenosed. Obstruction had been great.	Stenosed.	Aortic orifice roughened and contracted. Right auricle much dilated.
40	F.	17	Very hard life. No rheumatic history.	Admitted two fingers.	Scarcely admitted the point of the little finger.	Right cavities dilated. Left cavities dilated and hypertrophied.
41	F.	33	Not noted.	About two fingers' size.	About that of two fingers.	Aortic valves thickened and opaque. Both auricles exceedingly dilated.
42	F.	40	Not noted.	A small contracted circular aperture.	Semilunar fissure, scarcely admitting the handle of a scalpel.	Aortic aperture barely admitted the tip of the index finger. Both auricles dilated. Left ventricle hypertrophied.
43	F.	24	Two attacks of acute rheumatism.	Just admitted three fingers.	Just admitted three fingers.	Aortic valves thickened and incompetent. Left auricle enormously dilated, measuring 3½ in. by 4 in.
44	F.	29	Acute rheumatism at 18, at 27, and at 28 years of age.	Circumference of only 2 in.	Circumference of only 1⅝ in.	Great dilatation of right auricle. Constriction of aortic orifice. Circumference only 1¼ in.
45	F.	48	A history of acute rheumatism.	Much contracted.	Much contracted.	Recent pericarditis. Aortic valves incompetent.
46	F.	26	Acute rheumatism 3 years ago.	Admitted only tip of one finger. ⅜ in. in length, ¼ in. broad, 1¼ in. in circum.	⅓ in. in length; ¼ in. in breadth.	Much dilatation and hypertrophy of all the cavities, especially the right auricle.

NOTE.—A column of references has been omitted from want of space. Its information has been condensed in the form of a bibliography given at the end of this communication.

interesting and very important. She enjoyed good health till she was eighteen years of age. She then suffered from an attack of acute rheumatism from which she seemed to recover perfectly, and continued in her usual health for nearly four years. Then one day while carrying a heavy child she was suddenly seized with pain in the left side and great dyspnœa. She came as an out-patient to the London Hospital, was "told only to rest, took some medicine, and the pain gradually went." From that time, however, she suffered from some dyspnœa on exertion. Five years after this, in 1878, she was admitted into the hospital for jaundice, and I find it was then noted that there was a presystolic murmur localised at the apex, and a faint systolic "whiff" audible at the base. During this year she suffered from a second attack of acute rheumatism. The following year, 1879, she was admitted with a third attack of that disease, and I find it now noted that the presystolic murmur at the apex was loud and rough, and that moreover there was a harsh systolic murmur at the base, other cardiac signs remaining as previously noted. Finally, in the beginning of 1880, she was again admitted. It was now found that these signs still persisted, but that, in addition, the presystolic murmur, instead of being, as heretofore, distinctly localised at the apex, which throughout had shown its impulse an inch and a half below and external to the left nipple, was now audible also over a large area and very distinctly at the left margin of the ensiform cartilage. The area of cardiac dulness was laterally increased, extending to the right edge of the sternum, and pulsation was strong and diffused over the whole of this area. There was a well-marked thrill sensible at the apex and at the fourth left interspace. The main clinical features were cyanosis, orthopnœa, cough, distension of the jugulars, feeble and very slow pulse (42), with intermittency and irregularity. The temperature was subnormal, the urine varied from 50 oz. to 10 oz. per diem, and contained albumen.

The autopsy revealed great increase in the size of the heart, the left cavities and the right auricle being much dilated. The tricuspid, mitral, and aortic orifices were all much thickened and contracted, the tricuspid having a circumference of 2 in., the mitral a circumference of 1⅝ in., and the aortic 1¼ in. All the other organs of the body were in a state of chronic congestion.

CASE 3. (No. 46 in Table I.)—R. A——, an unmarried female, a domestic servant, aged twenty-six, was admitted into the London Hospital in July, 1880, under the care of Dr. Samuel Fenwick. Three years previously she had suffered from a severe attack of acute rheumatism. Till then she had always enjoyed fairly good health, but from that time she suffered from dyspnœa, cough, and palpitation. On admission the main clinical features were cyanosis, orthopnœa, much distension of the jugulars, and anasarca. Pulse very small and quick (96), and fairly regular. Urine very scanty (18 oz. to 10 oz. daily), containing albumen. Temperature normal. The point of cardiac impulse was just below the left nipple, and on the nipple line. The area of dulness was square-shaped, measuring 4 in. by 4 in., and extending beyond the right margin of the sternum. There was a well-marked presystolic thrill sensible over the greater part of this area, and chiefly it was noted to the right of the nipple. A loud presystolic bruit was heard, loudest to the right of the nipple, but audible also to the left; and it was remarked by Dr. Samuel Fenwick that the point of greatest intensity of sound shifted from side to side, never being equally loud over both sides of the heart at the same time. Occasionally there was a tumultuous cardiac action, and then pulsation was visible over the whole of the left chest.

The autopsy revealed a much enlarged heart (weight 18 oz.); the auricles much dilated, especially the right; the ventricles dilated and hypertrophied; the mitral valve was greatly thickened and rigid, and the orifice contracted to a narrow slit, one-third of an inch long by about a quarter of an inch broad; the tricuspid orifice greatly altered, the edges of the valves being so united that they were converted into a kind of curtain stretched between the right auricle and the right ventricle. In the centre of this curtain there was a small, almost circular, orifice, three-eighths of an inch in length and a quarter of an inch in breadth, and having a circumference of only one inch and a quarter. All the other organs were in a state of chronic congestion.

(To be concluded.)

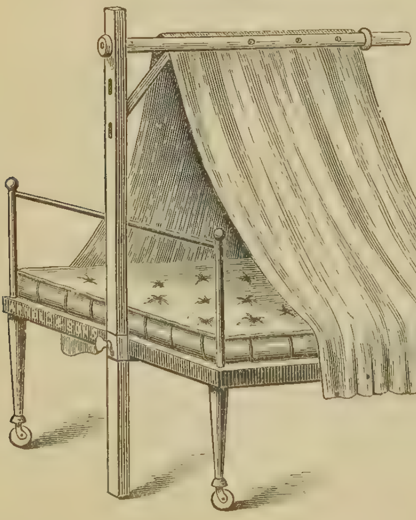
A NEW AND CONVERTIBLE SURGICAL APPARATUS.

BY JOHN WARD COUSINS, M.D. LOND., F.R.C.S.,
SURGEON TO THE ROYAL PORTSMOUTH HOSPITAL.

I BEG to introduce to the notice of the profession a very simple and convenient apparatus, which can be used for a great number of surgical purposes by making slight alterations in the component parts. Its special feature consists in the application of lever action over the bed without weight or contact with the bed itself. By a mechanical contrivance of great simplicity a lever is sustained immovably in any position, and by this means many of the ordinary surgical instruments, including the fracture swing, the bed cradle, the extension pulley, the bath hoop, the splint elevator, and bed rest are reduced to the form of one efficient, portable, and economical apparatus. The following is a short description of some of the principal applications.

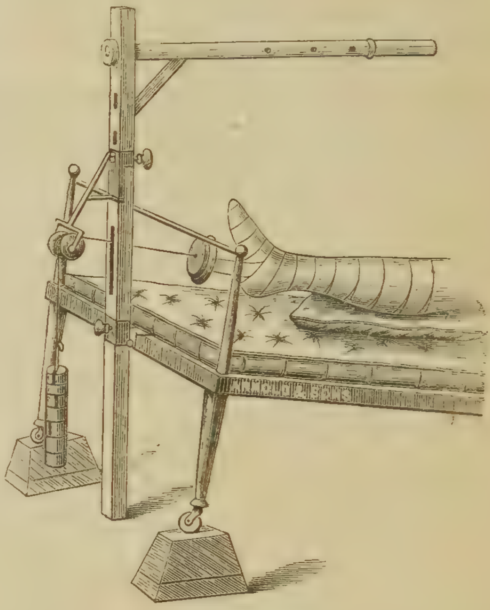
The bedclothes elevator (Fig. 1) is adapted for every case in which part or all of the bedclothes must be raised from the body of the patient. It can be instantly applied and adjusted to any part of the bedstead, and it will be found both in hospital and private practice far more convenient and comfortable than the old-fashioned bed frame. It never comes in contact with the patient, and never rests on the bed. It can be adjusted inside or outside the bedclothes, and it can be also regulated to elevate them any convenient height from the patient. The elevator serves also many other useful purposes. It will suspend a weight or ice-bag in any position, and it can be converted into a very convenient stand for a vessel or lamp.

FIG. 1.



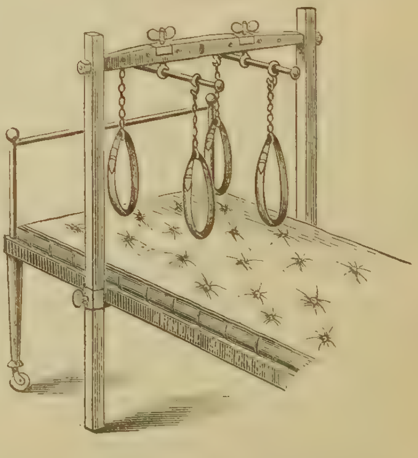
Extension by weight is now universally employed in many forms of injury and joint disease, and this kind of treatment is regarded by all surgeons as extremely simple and efficient. Fig. 2 represents the bedclothes elevator fitted with an extension pulley, which is suspended by means of a sliding bracket from the back of the instrument, and is thus capable of adjustment at any convenient height. A sliding collar, with a clamp working on a hinge, is also supplied for the purpose of fixing securely the upright to the bedstead in those cases in which counter-extension is obtained by raising the foot of the bed.

FIG. 2.



The fracture swing, Fig. 3, is another application of this apparatus. The swing is supported by two uprights, which are secured to the sides of the bedstead. It can be used with any kind of ordinary splint, and it supports the limb at any required height; at the same time it can be used to swing both legs, if necessary, without any addition to the apparatus. Moreover, it occupies no space in the bed, permits a free circulation of air under the bedclothes, and does not require to be removed in

FIG. 3.



dressing the limb. The apparatus is also convertible, by a very simple arrangement of wooden rods, into an elevator of the entire bedclothes, which will be found of great service in the application of hot-air and vapour-baths (Fig. 4). The cross-bar can also be placed over the bed for a rest in cases of lung or heart disease, in which the patient is unable to lie down, and a wooden stand can be adjusted on it to hold an inhaler, or other vessel. The elevator can be used as a splint rest, and it will be found useful in all cases in which a limb requires elevation (Fig. 5).

FIG. 4.

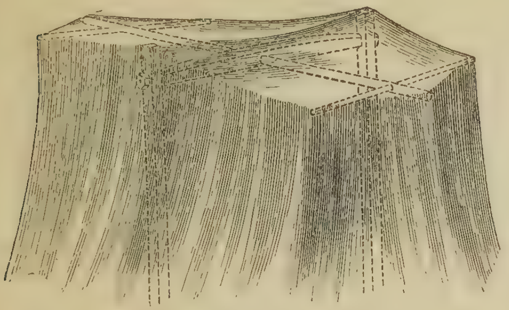


FIG. 5.

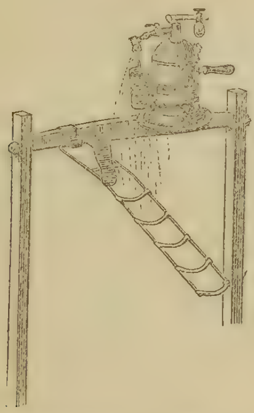

Special iron wire splints fitted with shifting bars and movable hand and foot pieces, form a part of the apparatus, and by means of a sliding metal rest they can be adjusted on the cross-bar at any convenient height. This method of elevation will be found very convenient in practice, and is especially adapted for the treatment of injuries and fractures, wounds of the hands and feet, amputation cases, and many other diseases in which absolute rest and elevation of the limb are essential.

Southsea.

THE MILK FEVER EPIDEMIC IN ABERDEEN.

BY J. M. GORDON PIRRIE, M.D.

IN the city of Aberdeen an epidemic of a novel character has mysteriously appeared in our midst, which has been properly or improperly named, *pro tempore*, the Old Mill Reformatory Milk Fever. The reason why it has received this appellation is from the fact that all the persons affected with the ailment, the symptoms of which will be presently described, have been partaking of milk supplied from the dairy in connexion with that institution; and no one has as yet been affected, so far as I am aware, who has not used the above-mentioned milk.

The first case of this epidemic which came under my notice occurred on April 1st. Since then fifty-eight families in Aberdeen, comprising over two hundred individuals, have been affected with this peculiar ailment. Three cases have terminated fatally.

Symptoms.—The patient, the subject of this disease, who, in most cases, has been up to the moment of seizure enjoying the best of health, is suddenly seized all over the body with a cold sensation and frequent rigors. This state of matters lasts in some cases for twelve or sixteen hours, and for a time all attempts on the part of the physician or of the patient's friends are fruitless to restore to the patient his natural feelings of warmth. During this cold stage or period during which rigors occur the skin is hot and dry. The pulse becomes rapidly and greatly accelerated, and in two cases under my observation amounted to 135 beats per minute. Another striking feature in this ailment is the sudden rise of the temperature of the body to 103° F. In two cases the temperature rose to 105° F., and remained at that high figure for nearly twelve hours. Variations of temperature do not occur as in some other cases of fever, it being as high in the morning as at night. The patient complains of intense thirst, great prostration, pain in the head, neck, back, and limbs, and sickness, which is usually accompanied by fits of vomiting and violent retching. The matter vomited has at first been the contents of the stomach and afterwards mucus mixed with bile. Pain in the head is a prominent and early symptom, but the character of this pain varies. Sometimes it is described by the patient to be of a bursting nature, at other times as if the parietes of the cranium were being drawn together and the eyes drawn inwards. The pupils of the eyes do not appear to be affected in any way. In one case the sensation of weight in the head was so great that the patient was unable to move the head on the pillow.

Perhaps the most striking feature in this complaint, along with the sudden appearance of rigors, the quick and great rise of the pulse and temperature, is the rapid and painful swelling of the glands and muscles of one side of the neck, and in the cases I have seen it has been the left side of the neck that was affected. In one case the glandular swellings extended down the neck to within two inches of the clavicle. These swellings of the glands and muscles are very painful under pressure.

Sore-throat is also complained of by the patient, and on examination I found only the tonsil on the affected side of the neck inflamed and slightly swollen. The amount of inflammation and swelling of the tonsil, the surrounding tissue, and the mucous membrane, was not at all in ratio to the amount of pain complained of. Two patients experienced a feeling of great tightness about the œsophagus and trachea, and in these cases difficulty of swallowing was present, but I could not discover any sufficient cause to account for it. In another case difficulty of breathing was experienced for several hours, which, however, subsided by causing the patient to inhale the steam of hot water. The shivering, the pain in the head, the sickness, the swelling of the glands and muscles of one side of the neck, and the soreness in the throat, usually appear in rapid succession. The tongue is coated with a yellowish-white fur, while its edges appear to be more red than natural. The urine is very acid, high-coloured, scanty, and loaded with urates; no albumen was present in any of the samples which I examined. The bowels are usually constipated; diarrhœa has not been present in any of the cases under my observation. The patient feels very uneasy and restless. Sleep is disturbed, of short duration, and unrefreshing. Delirium has been present in some cases. After the patient has been sharply purged, and diaphoresis thoroughly established, the pulse and temperature fall somewhat rapidly, the painful glandular and muscular swellings decrease, the sickness and vomiting abate, and in two or three days the patient may be said to be convalescent. A relapse of all the symptoms has occurred, in most of the cases under my notice, a day or two after the patients were convalescent; and, in such cases, it was always the glands and muscles of the opposite side of the neck from those first affected which became painful and swollen. One patient who was in a delicate state of health previous to being attacked with this complaint has had three relapses, but the symptoms during the relapses have been less severe than those at the onset of the disease in all the cases under my notice. The treatment I adopted, and which was successful in the cases under my care, was frequent purging, the administration of saline diaphoretics until diaphoresis was well established, and, after the more urgent symptoms had abated, I found the greatest benefit to follow the administration of quinine along with the most nourishing food, accompanied by a well-regulated amount of stimulants. A sample of the milk in question was put into Professor Brazier's hands on Tuesday, the 5th of April, to be chemically examined, and the following is his report:—

"The sample of milk chemically considered appeared to be one of fair average quality. The proportion of water and of saline matter was by no means abnormal, and gave no reason for suspecting any admixture or adulteration therewith. The only thing that attracted my attention was the somewhat rank odour possessed by the milk, and which manifested itself the more by allowing the milk to rest for a time in a vessel half full and loosely covered. If, as I have been led to believe, the milk in question has been blamed for giving rise to a series of sicknesses, the investigation as to the cause must be handed over to the pathologist or physiologist or both to determine, rather than the chemist."

By order of the proper authorities, a thorough investigation is now being carried on regarding the origin of this epidemic, and it is to be hoped that the cause of this serious disease may ere long be conclusively determined beyond all doubt.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.

CASE OF SECONDARY INTRA-THORACIC CANCER; NECROPSY.

(Under the care of Dr. THOROWGOOD.)

LOUISA B——, aged forty-three, married, was admitted on Nov. 8th, 1880, and the following history taken:—She had had twelve children, eleven born prematurely and dead; the other died in childhood from bronchitis. Six or seven years back she first noticed a lump in left mamma, which continued slowly but painlessly increasing for three or four years ago, when tearing pain supervened in that region. She went into the German Hospital at Dalston, and had the breast removed in June, 1879. About a fortnight before admission into Victoria Park Hospital she noticed a small hard lump close to the cicatrix on the left side, and at the same time two or three lumps in the right axilla. About the beginning of August, 1880, she first found her breathing to be oppressed, the dyspnœa coming on rather suddenly. Cough, with muco-purulent sputa and night-sweats, came on, but no hæmoptysis. She had suffered a great deal of pain under the upper part of the sternum, and at the right lower part of the chest in front. She had been in bed since the end of September, gradually getting weaker. Appetite very bad. Was getting much thinner, and the dyspnœa increasing.

On November 9th she was examined by Dr. Thorowgood, and the following notes were taken:—The patient has a cachectic appearance; there is a small nodule in the site of the old cicatrix over the left mamma; one or two enlarged glands in the left axilla; several enlarged glands in the right axilla, and above the right clavicle. No œdema of feet; under the left clavicle percussion-note fair; breathing harsh, with prolonged crowing expiration, heard all over the left front. Under the right clavicle resonance good to the second rib, where dulness commences and continues to two fingers' breadths below the level of the ribs. Respiration is bronchial, mixed with sonorous and subcrepitant râles. At the level of the third rib sounds are weak, and at the right nipple inaudible, also in the right axillary line. The liver appears depressed below ribs and is very tender. Posteriorly, the left back is resonant, and the respiratory murmur loud and strong. At the right supra-spinous fossa breathing is heard, but cough resonance not increased. Crepitation in the right vertebral groove, at the right base the respiration *nil*, vocal vibration *nil*.

On the 27th paracentesis thoracis was performed in the sixth interspace at the anterior axillary line, and about one ounce of blood-stained serum was withdrawn. (This was not examined with the microscope.)

On Dec. 4th paracentesis was repeated in the fifth interspace at the anterior axillary line. No fluid was withdrawn. On the 31st the right side of the chest looked large and rounded; cyrtometer tracing showed marked difference between the two sides. Right, eighteen inches and a half; left, sixteen inches and a half. Below mamma the right did not move with respiration; intercostal spaces could be scarcely distinguished with the fingers. The heart's apex was one inch outside the nipple line in the fifth interspace. Vocal vibration was absent over all the right side, except at the extreme apex, where it was much diminished. Veins enlarged in the right axilla. Slight œdema. On percussion at the right apex, from the clavicle to the second rib the resonance was high-pitched, boxy. Below the second rib there was dulness, which extended fully one inch to the left of the sternum, and was continuous with the area of cardiac dulness. The right back was dull, except a little high-pitched resonance at the supra-spinous fossa, and there was some obscure resonance in the vertebral groove. The dull area presented a feeling of solidity to the fingers, and considerable resistance to percussion, hardly suggestive of a large fluid effusion. At the left back the resonance was normal. On auscultation at the right apex, front and back, there was some vesicular breathing, with prolonged expiration. Below the second rib in front the breathing-sounds were, for the most part, absent. Feeble bronchial breathing was heard all over the lung behind down as far as the base. The signs were similar in the right axilla; no bronchophony; heart sounds audible over the whole of the right back and side. There was no pleural friction; right side vesicular breathing; vocal resonance rather increased. The heart sounds were clear; no pericardial friction; no evidence of any pressure on vessels or nerves of thorax or œsophagus. During the last few days a small irregular lump, fixed and painful, had appeared at the inner border of the right mamma. Sputa for the last fortnight abundant, frothy, of light amber colour; microscopic examination revealed epithelial elements, but nothing specially distinctive of the intra-thoracic disease. Treatment, which consisted in the administration of small doses of iodide of arsenic, liquid extract of ergot, and, lastly, pills of Chian turpentine, exercised no influence over the extension of the disease, and after much increase of dyspnœa the patient died on January 22nd 1881.

The post-mortem examination was made fifty hours after death by Dr. S. West and Dr. Lawrence Humphry, notes being taken by Mr. Batson. Moderate height; not much emaciated; no rigor mortis. Right side of chest markedly bulged. In site of left mamma a long healthy cicatrix. Above this was a small hard nodule, which, on section, was soft medullary cancer. Skin over right mamma adherent; the mamma and surrounding tissues were adherent to the chest-wall; numerous small hard nodules upon the sternum and ribs. On removing the skin and making a section of the mamma these nodules were found to be cancerous. On opening the abdomen the liver was found enlarged and depressed, the whole peritoneum and omentum were thickly sown with small nodules, most numerous along the attachment of the large intestine, but also abundant in the mesentery. The lumbar glands were slightly enlarged. In the pelvis all the organs were matted together, especially posteriorly, where the nodules were most numerous. Both ovaries were converted into cysts, the left two inches in diameter and loculated. Liver weighed 4 lb. 5½ oz., and contained a few secondary deposits of very small size. Along the suspensory ligament the cancer had spread, but remained almost entirely in the capsule. The kidneys and spleen were congested. The left suprarenal capsule contained several nodules, the largest in the medulla. The diaphragm on the right side stood very low and was slightly convex downwards. The left lung was bound down by loose adhesions, consequent upon pleurisy, and which was due to small disseminated nodules in the visceral pleura, chiefly on the posterior surface. There were no nodules in the lung. The heart was displaced to the left; no fluid in pericardium; heart normal. From the pericardium, extending upwards to the top of the sternum, occupying the whole of the mediastinum, was a solid mass, extending through the intercostal spaces to become continuous with the nodules described in the skin. This was clearly cancer. It had involved the whole of the right pleura and diaphragm, the lung being collapsed, and forming a solid, airless, and adherent mass in the upper part of the chest. Below was a large cavity, filled with blood-stained fluid, the walls formed by the cancerous pleura and diaphragm. Dr. Humphry examined sections of the thickened pleura under the microscope, and observed scirrhous cancer extending from the pleura into the lung between the alveoli.

Remarks.—It was interesting to observe in this case how the cancer had spread along the serous surfaces. Only one or two small nodules of cancer were found in the liver, and the lung was pressed and collapsed by the thickened pleura. The under surface of the diaphragm and the serous membranes of the abdomen were thickly studded over with cancer, while the kidneys and spleen were simply congested. In exhibiting the specimen before the Pathological Society, on March 15th, Dr. West suggested that the failure of the attempts to draw off the fluid by thoracentesis was due to the rigid condition of the walls of the cyst, which would not allow it to collapse.

SUSSEX COUNTY HOSPITAL.

CASE OF STRICTURE OF RECTUM IN A BOY; COLOTOMY; RELIEF.

(Under the care of Mr. N. P. BLAKER.)

FOR the following note we are indebted to Dr. J. C. Uhthoff:—

William E——, aged sixteen years, was admitted on November 6th, 1879, complaining of offensive discharge from the rectum and painful defecation. He was an errand boy in a shop, and had been sent to the hospital by his employer, who complained that the smell emanating from him was so offensive that his shopmates could not endure it. He was a somewhat undersized lad and looked pale and ill in the face. He said that he suffered much pain in the rectum, and that defecation, which was painful and frequent, was accompanied by the discharge of blood and mucus. He was quite well until six months before, when pain in the abdomen, followed by the rectal symptoms, commenced. During this time he lost flesh and strength. He stated that his mother died of a similar complaint.

Examination of the rectum revealed a tight annular stricture about an inch or an inch and a half above the anus; the tip of the forefinger could be passed into it, but nothing more. The surrounding tissues were very hard and firm, and nodular in parts; but nothing in the way of ulceration could be felt, and the hardness was rather that which characterise firm fibroid tissue than the stony hardness of malignant disease. On withdrawing the finger, it was found covered with very offensive blood-stained mucus. After his admission he was treated with mild aperients to soften the fæces, with morphia suppositories to relieve the pain and tenesmus, and with solution of perchloride of mercury and iodide of potassium, as it was thought that the stricture might be of a specific nature. His condition varied; at times he seemed easy and the abdomen flaccid, and he was able to get up and about; at others he had much pain and tenesmus, and the abdomen was distended. The condition of the stricture remained much the same, and the motions were always narrow and offensive from the presence of muco-purulent matter.

Towards the end of January, two and a half months after his admission, the symptoms of obstruction were somewhat pressing, and it was decided to perform colotomy in the left loin. The abdomen was much distended and very painful, and any attempt at defecation was accompanied by much increase of pain; the general condition was also unfavourable, and the boy was evidently failing. The operation was performed on January 31st by Mr. Blaker, under anæsthetic mixture of alcohol, chloroform, and ether. The oblique incision was made use of, and great assistance in finding the colon was afforded by passing a small catheter through the stricture of the rectum, and distending the bowel with air.

A large quantity of liquid fæcal matter passed through the artificial opening during the next few days, and the relief of the obstructive symptoms was marked and rapid. The operation wound healed well, though slowly, and with a considerable amount of inflammation. The patient rapidly regained flesh and strength, and left the hospital on June 21st, 1880, to return to work. The bowels acted regularly through the artificial anus; a slight discharge still continued from the rectum, but was not accompanied by any pain, was seldom blood-stained, and had but little offensive odour; the stricture appeared in much the same state as on his admission.

It should be added that as he was recovering from the operation he was troubled by the occurrence of an ischiorectal abscess, which after its discharge left a fistulous opening on the left side of the anus, and about an inch and a half external to it.

He was readmitted on February 5th, 1881, complaining of pain and swelling on both sides of the anus. Since his discharge in June he had been at his work, and had continued to improve in general health. He had had, as a rule, but little discharge from the rectum, and little or no pain. The bowels had acted well through the loin, but he had been somewhat troubled by prolapse at the opening. There was now redness, swelling, and tenderness on each side of the anus; the swelling was very hard and irregular, and some doubt was felt as to its cause. But in a few days pus was discharged from either side, and the local inflammatory signs subsided, leaving two small fistulous openings. That on the left side passed to the rectum, about an inch above the anus and just below the stricture; that on the right side passed more deeply, and if it opened in the rectum must have done so above the stricture.

At the end of March the boy was still in the hospital and helped in the ward; his general health was good and he looked fat and well; but the stricture remained as tight as ever, and the fistulæ continued to discharge.

Remarks.—The particular interest attaching to the case is its rarity; no similar case being apparently on record. The nature of the stricture is very doubtful, that it is malignant is improbable, for the boy is fat and well, and the growth shows no signs of breaking down or invading surrounding structures; that it is syphilitic may be more likely, but there is no other evidence to uphold such a diagnosis.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Vascular Protrusion of the Eyeball.—Nephrectomy by Lumbar Section.

AT the ordinary meeting of this Society, held on the 12th instant, Dr. Barclay, President, in the chair, a paper was read on a case of Vascular Protrusion of the Eyeball by Mr. Charles Higgens, of which the following is an abstract:—The case was that of a woman aged forty-two. The disease appeared to have arisen spontaneously, and had been gradually progressing for six months. The symptoms were not very urgent, but increased steadily in severity in spite of rest, low diet, ice to the head, and purgatives. Six weeks after admission the common carotid was ligatured, with the result that a complete cure was effected, and the patient left the hospital two months later perfectly well. The daily progress of the case was given. At one time there was hemiplegia, which entirely passed away; otherwise no dangerous symptoms arose. A sketch of the patient's eyes was shown taken a week before the operation. Abstracts of two other cases were given.—Mr. HOLMES asked whether the pulsation had recurred, for if so the ligature of the carotid would have been without permanent effect. The real nature of these cases was obscure; in some an aneurism was said to exist, but this appeared uncertain. In the two cases related in the paper, where an examination was made, there did not appear to be anything like aneurism, and nothing which could have called for ligature of the carotid. Mr. Higgens's case resembled others which do as well when left alone. Ligature of the carotid was only justifiable when the disease is increasing and threatening life. In Mr. Rivington's case pressure on the carotid failed, and so did injection of perchloride of iron. Mr. Holmes had seen cases where the protrusion had remained stationary for years.—

Mr. HIGGENS had seen the patient last week; there was no pulsation in the superficial vessels on that side of the head. He would not be in a hurry to ligature the carotid again, for he had seen another case since with more urgent symptoms and blindness, the symptoms afterwards subsiding. The question was how long should one wait before resorting to ligature? In the case related compression of the carotid did no good, nor did rest and the application of ice, and, as the symptoms increased, ligature was done.

Mr. ARTHUR E. BARKER then read a paper on Nephrectomy by Lumbar Section. The basis of this paper is a record of two cases in which the author had recently performed nephrectomy by lumbar section for calculous pyelitis. But before considering them in detail, a brief review is given of the whole question of excision of the kidney in the light of all those cases he has been able to collect. Referring to a paper published in last year's Transactions of this Society, in which he tabulated 28 cases of this operation, he points out that of this number 14 recovered and 14 died; but that, deducting those 6 cases in which the operation was performed upon a wrong diagnosis or undesignedly, there remained 13 recoveries and 9 deaths. Passing on then to the new collection, 26 in number, he shows that 12 recovered and 14 died in the gross; or, making the same deduction as above (of 5 cases) that 11 recovered and 10 died out of the remaining 21. Adding the latter to the 22 designed nephrectomies of last year's table, he finds that, out of the resulting 43, recovery took place in 24 and 19 died. Two recoveries where nephrectomy was not premeditated might further be added to these 24. The causes of death in the 28 fatal cases of the combined tables are shown to be as follows: Peritonitis, 8; shock and collapse, 5; pyæmia, 2; uræmia, 2 (in one of these the other kidney had been destroyed by old disease; in the second it as well as the liver was found in a state of advanced fatty degeneration); wound of pleura, with consequent collapse of lung, 1; pulmonary thrombosis, 1; hæmorrhage during operation, 1; after operation, 2; exhaustion of vomiting, 1; œdema of lungs, with marked dyspnœa, 1; exhaustion from suppuration, 1; unrecorded, 3. Of the 9 fatal cases out of these 28 where nephrectomy was unpremeditated, 4 died of peritonitis; 1 of hæmorrhage during, and 1 after operation; 1 of suppuration and exhaustion; 1 of œdema of the lungs with marked dyspnœa; and in 1 the cause is not recorded. Of the two modes of operation—i.e., in the lumbar region and in the linea alba—the first shows the largest proportion of recoveries, but the author regards the mere numerical analysis of the cases as liable to mislead on this point in view of the varying nature of the conditions for which the operation was undertaken. A careful perusal of all the original records is alone to be relied upon for estimating the two methods correctly. The histories now recorded are briefly as follows: A married woman, aged thirty-two, was admitted into University College Hospital on June 16th, 1880, on account of a rapidly growing tumour in the left abdomen, first noticed seven weeks before, and accompanied by pain and much lassitude; the pain had existed since patient was five years of age. The tumour on admission measured 14 by 4½ inches, was smooth, and fluctuated obscurely. Diagnosis: Pyonephrosis probably due to calculus. On July 2nd the tumour was aspirated from behind and 18 oz. of fetid pus withdrawn. The next day it had refilled. Nephrectomy was performed on July 5th through an incision made downwards and forwards from midway between the last rib and crest of ilium for four inches. The enormously thickened capsule of the kidney was soon reached, and its removal with the contained kidney attempted. After considerable loss of time and blood from the vascular and inflamed tissue this line of action had to be abandoned on account of the extremely wide-reaching attachments of this mass of fibrous investing material. The organ itself was then sought for and was easily shelled out of its capsule with the finger and without loss of blood. The pedicle was tied with silk, not without difficulty, and the organ was cut away, after which some twigs spouted and had to be ligatured separately. The whole operation was conducted under Listerian antiseptics, and lasted one hour and ten minutes. The patient died three hours after its completion, of shock. The autopsy showed that it would have been next to impossible to have removed the capsular structures with the organ. They now lay as a great hollow mass of fibrous tissue attached to the spine. Enucleation of the organ alone ought to have been aimed at from the beginning. No bleeding had occurred after the operation, and the peritoneum was not torn. The next case is that of a woman, aged thirty-eight, to whom an operation for calculous pyonephrosis had been proposed seven months before and refused. The kidney was not at that time much enlarged, though a large stone was found in it by means of an aspirator needle. Six months later the patient requested the author to readmit her into hospital and perform any operation for her relief he might deem advisable, as she had suffered very severely in the interval, and was losing ground. On readmission she was very emaciated and bedridden on account of pain, the slightest movement even in bed causing much distress. On Oct. 5th an operation was undertaken with a view to remove the stone if possible, and if not, of excising the kidney containing it. An incision was made from the middle of the twelfth rib downwards and forwards for five inches, and the kidney rapidly exposed. An aspirator needle was then thrust into the organ and the stone struck, about two ounces of pus being withdrawn. A vertical incision was now made down to the calculus with a Paquelin's cautery knife through the cortex of the organ. The stone was very firmly fixed, and, when drawn on with a forceps, broke, one-half only coming away. Very great difficulty being apprehended in removing the remaining half, the excision of the whole organ was determined on. Warned by the last case, the surface of the kidney itself was sought for at once as a guide to enucleation, which was consequently easy. The difficulties of clearing the pedicle, however, were insurmountable in this case, and after many attempts to clear it, it was ligatured *en masse*, the ligature including much of the kidney tissue. It was not, however, possible to draw the silk close enough to justify cutting away the organ, which was therefore left *in situ*. In clearing the lower ends of the organ, something was felt to give way at one spot, to which it was firmly adherent, and it was suspected that the colon had been torn. The operation was completed by a Listerian dressing, having lasted one hour and twenty minutes. The patient died twelve hours later of shock. After death it was seen that the pedicle could not have been cleared, even though the last rib had been resected, which was now done for experiment, with ease and without any damage to the pleura. Also that any endeavour to remove the organ with its investing structures would have ended in failure, owing to the very extensive attachments of the latter. The colon was found to have adhered to the kidney and to have been torn at this spot, where it was soft and sloughy. The first point brought out by these operations appears to be the necessity of removing the kidney and it alone in such cases, and of not attempting to take away the investing structures with it. Again, the desirability of early operation, before the parts around the organ, and especially the pedicle, have become converted into a mass of dense inflammatory tissue. Thirdly, the want of every kind of data bearing on this operation, and either encouraging or discouraging its performance.—Mr. CLEMENT LUCAS, agreeing with the author's view as to the publication of unsuccessful cases, had not yet published a case of his own, in which fourteen months ago he had performed the operation with good result. The patient had been bedridden for three months with a sinus in the loin; the operation was difficult owing to adhesions, and severe secondary hæmorrhage set in two weeks afterwards, only checked by plugging the wound with sponges soaked in perchloride of iron. He saw the patient a month ago; the wound was healed and he had gained much flesh. In that case pus did not disappear from the urine for many weeks after the removal of the kidney, showing that much pus must come from the bladder and ureter. He thought the lumbar operation preferable to the ventral, except in some cases of tumour, and he advocated a vertical incision from the last rib, and another passing horizontally outwards to the quadratus lumborum. Mr. Morrant Baker in a recent case made a transverse incision, enlarging the wound in a vertical direction. He agreed with Mr. Barker as to the impossibility of removing the capsule with the kidney. In his own case no sign of uræmia, and no vomiting followed.—Mr. MORRANT BAKER felt strongly the importance of removing the kidney without the capsule. In his recent case (a child eight years old), nephrotomy was first performed, and finding that the removal of the kidney would be easy he determined to do this if necessary. But when he came to perform nephrectomy, two or three months later, the capsule had become so thickened that he was obliged to detach it. This was done without much hæmorrhage, no difficulty was met with as regards the pedicle, and the case did well. Apart from the risks of the operation itself, the removal of one kidney does not appear to have much influence. The child had fairly recovered from the effects of the operation in twenty-four hours, and no ill results ensued.—Mr. **BARWELL** had a case where death ensued shortly after operation. The patient was weakly, and passed much pus in the urine. He made a free incision into the abscess, evacuating much pus, and felt the kidney lying in the sac. The removal of the organ was easily effected, but it had to be detached from the crus of the diaphragm. A ligature was passed round the vessels and ureter, and the kidney then removed. The difficulty was to decide upon suitable cases, and to determine whether they could be dealt with by lumbar incision. He advocated free incision rather than aspiration in dealing with the perinephritic sac in the first instance, for the kidney could then be felt. The incision could be the same as for lumbar colotomy, and antiseptic precautions should be used. In a case of perinephritic abscess under the care of Dr. Silver, Mr. Barwell made a free incision in preference to aspiration, let out thirty-five ounces of pus, felt the kidney, which seemed healthy, inserted a drainage-tube, and the case recovered. The case of nephrectomy to which he had referred proved fatal on the fifth day, the patient dying comatose apparently from uræmia. The other kidney was found to be also the seat of tuberculous disease, so that had the operation been earlier performed the result might have been different. — Mr. **BARKER**, in reply, was glad that Mr. Baker had confirmed his view upon the desirability of removing the kidney from the capsule. Mr. Barwell's suggestion of an exploratory free incision was a good one. In a case of suspected tubercular disease he had preferred such exploration to excision, and evacuated much pus with considerable benefit. The patient survived two months, and after death both kidneys were found to be tubercular. In nephrectomy the time at which the ligatures come away from the pedicle, when this is tied *en masse*, is often much delayed, sometimes after the space of many months.

Mr. **HOLMES** exhibited a simple instrument invented by Dr. Howard for plugging the nares in epistaxis. It consists of a bag of india-rubber, which, after insertion in the nares, can be inflated with air to the required size, and, exerting equable pressure, speedily checks the hæmorrhage. It is made by Walters of Palace-road.

The Society then adjourned.

CLINICAL SOCIETY OF LONDON.

Syphilitic Psoriasis of Head and Neck.—Arterial Hæmatoma of Forearm.—Meningocele.—Progressive Painful Inflammation of Arteries.

THE ordinary meeting of this Society was held on the 8th inst., T. Smith, Esq., Vice-President, in the chair. The chief communications read had reference to some rare diseases of the vascular system.

Dr. **BERNARD O'CONNOR** read notes of a case of Syphilitic Psoriasis of Face and Neck. The patient, a female aged twenty-eight, came first under observation on March 2nd, 1881. She had been healthy up to six months ago, when she complained of pains in the head, most severe in the temples. A week subsequently there was sore-throat, and a fortnight later a general eruption appeared, that on the body and limbs being of the form of "dark bluish spots." Her husband had a few weeks earlier presented the same symptoms, with the exception of the peculiar rash on the face. He had also had a severe iritis, but never had a chancre. There were two healthy children, and the patient had never miscarried. The eruption on the face consisted of a number of pinkish-white scaly rings, and some darker circles all over the face, including the eyelids, and on the front, sides, and back of the neck. The rings were in all stages of development with spreading margins, and were not quite symmetrical; they were incomplete at points of contact. The eruption was dry, and there was itching. There was no trace of it on the elbows, knees, palms and soles, mucous membranes, ears, or scalp; but the hair had been shed in large quantity, and there was dry seborrhœa. A few brownish roseolous maculæ occurred on the body, back of thighs, and inner side of arms. There was no affection of the nails. The eruption on the face resembled somewhat lichen ruber and herpes circinnatus; but under the microscope there was slight hyperæmia and infiltration of the rete mucosa. The absence of any implication of the palms and soles was unusual in syphilitic psoriasis, which the case was proved to be by its history and features as well as by the rapidity with which the eruption cleared away under mercurial treatment.

Mr. **RUSHTON PARKER** read notes of a Case of Arterial Hæmatoma of the Forearm due (apparently) to embolic arteritis and perforation. William G——, aged fourteen, had rheumatic fever in the first quarter of 1879, during which he experienced pain in the right forearm, followed by swelling of the whole limb, eventual subsidence in the arm but gradual increase in the forearm. He was admitted into the Liverpool Royal Infirmary on July 23rd, 1879, and was found to have an oval swelling of the right forearm, tense, slightly elastic, without pulsation (the previous existence of which the patient distinctly negatived). Incision under ether revealed a blood tumour between the bones and deepest muscles on the flexor side, and an open artery with upper and lower apertures. This vessel was tied and the wound treated by the carbolised method without the spray. Inflammation however became intensified, and septic conditions arose, without, however, any evil result until after the twentieth day, between which and the thirtieth several attacks of secondary hæmorrhage occurred. The wound was eventually searched for a bleeding point, but none found, the oozing being general. Ergotine subcutaneously, and turpentine locally, with elevation of the limb, were followed by cessation of bleeding and rapid cicatrisation. Hitherto no cardiac or respiratory symptoms had been present, though a systolic and diastolic murmur revealed aortic obstruction and regurgitation, both on admission and since. He now, after the sixth week, had severe dyspnœa with palpitation, and cardiac pain, commencing with an attack of epistaxis and producing cyanosis. Opium and digitalis were given, and in a fortnight he was better with occasional remissions. Under a regulated diet of bread, butter, potatoes, tea, and beef-tea, excluding especially milk and flesh, with opium and no digitalis, he gradually made a complete recovery from all impairment of the respiratory and circulatory functions. The murmurs, however, remained for months, but he was lately (Feb. 1881) totally free from murmur, and in robust health and strength. Partial division of the median nerve, in the final operation, has resulted in impairment of the palmar muscles concerned, but the main use of the hand is good, and all the most important movements preserved. Mr. Parker remarked that the appearance of septic influences is of course due to causes which were probably preventable; and the secondary hæmorrhage was almost certainly due to the intensified inflammation which ensued. This case is only one among many examples, which to many surgeons are well known, proving in the clearest way the influence of inflammatory irritation in promoting hæmorrhage from vessels in the vicinity. The converse, though not demonstrable here, is experienced in other cases, where the removal of irritation (such as the distensile force of retained discharge or blood-clot) is followed immediately by cessation of bleeding, which may previously have been profuse and apparently uncontrollable. As to the original blood-clot, the hæmorrhage of which it was the substance, resulted evidently from perforation of the artery concerned. The blocking of this artery, and the consequent fluxion, are circumstantially evidenced in the history, while the conditions requisite for embolism were, to say the least, rendered possible by the clinical signs. The age of the patient and all the circumstances leave, it is thought, no choice outside the supposition that an embolus consisting of active inflammatory material, on becoming impacted in the anterior interosseous artery of the forearm, led to acute arterial inflammation and consequent perforation in place of the obliteration more commonly to be expected.—Mr. **T. SMITH** thought the explanation given the only probable one, and remarked upon the infrequency with which embolism in a limb leads to hæmorrhage as compared with cerebral embolism.—Mr. **GODLEE** asked whether the chest symptoms were attributed to aneurism, or whether there was evidence of arterial disease in other regions.—Mr. **HEATH** said it would be most unusual to meet with arterial disease at the age of fourteen. He could not understand how two openings should occur in the vessel from embolism, and asked whether any possibility of injury or strain had been excluded. The case might have got well more quickly had the wound been stuffed with lint, and no attempt made to close it.—Mr. MORRANT BAKER asked how long since the disease had the boy been seen, pointing out the occurrence of cases of blood cysts with a thin wall of sarcomatous tissue, afterwards developing into a tumour.—Dr. COUPLAND inquired if there was any evidence of embolism in other arteries—e. g., splenic or renal—and remarked upon the complete disappearance of the signs of valvular disease as a notable feature in the case.—Mr. RUSHTON PARKER, in reply, said that the age of fourteen excluded aneurism or arterial disease. He supposed the two openings might have been formed by the plug being in a branch coming off at right angles to the vessel. There was no possibility of any traumatic cause, and the idea of embolism was only entertained after the operation, which took place within one hour of admission. The puncture by the aspirating needle, and subsequent exploratory incision, were made because of the suspicion of malignant disease. The needle could hardly have reached the artery, which was deeply situated. The history was that of embolism, and the blood appeared to have gradually accumulated. The aortic murmurs were repeatedly observed by Dr. Glynn during the patient's stay in hospital, and an unfavourable prognosis was given. The opium and restricted diet were given because of the heart disease, and the total disappearance of the bruits was certainly remarkable. There was no evidence of the embolism elsewhere. In reply to a further question by Mr. Heath he added that the openings were about three-eighths of an inch apart, and the artery was not divided before ligature.

Dr. STEAVENSON read notes of a case of Meningocele. A female child, the last of a family of thirteen, was brought to the Children's Hospital when three weeks of age, with a cleft in the cranial and facial bones extending from the posterior fontanelle to the alveolar process of the jaw. Between the widely-separated eyes and nostrils was a tuberous swelling communicating freely with the cranial cavity. There was no cleft palate. Respiration was peculiar, a few short quick inspirations being succeeded by a pause, and the heart's action was accelerated. The mother stated that when she was three months pregnant she was much frightened by seeing the body of her son in a hospital mortuary, and to this fright she attributed the infant's deformity. The child lived to the age of four months and a half, and a post-mortem examination was refused. Out of thirty-nine cases recorded by Lawrence, twenty-one were males and eighteen females. In fifty-three out of seventy-nine cases the meningocele has been occipital; in six instances adult life was attained, the majority dying in early life.—Mr. T. SMITH had seen the child during life, and had never seen so extreme a case. It was remarkable that it should have lived so long. He added that the history of maternal impression was very clear, the mother stating that she had been much shocked, when viewing the body of her son, by placing her hand on the head and feeling the vacuity in the forehead left by the post-mortem.

Mr. JOHN H. MORGAN read notes of a case of Progressive Painful Inflammation of Arteries. G. W——, aged forty-six, contracted syphilis at eighteen, has since married, and has several healthy children. He is the subject of a curious congenital enlargement of superficial veins of chest and abdomen. Nine years ago he was a patient at Guy's Hospital under Dr. Wilks, who has described his case. In 1876 he suffered pain in the left armpit, which passed down to bend of elbow, and then left him. In 1877 he came under Mr. Morgan's care, suffering from pain in the left arm, for which there seemed no evident cause. There was no swelling, and he soon recovered from this attack. In 1880 an attack of sudden and severe pain in right groin, deep seated, and made intense when the part was pressed. The area of pain was confined to two to three inches in the course of the femoral artery, and to one to two inches on either side of it. This pain gradually travelled down in the course of the artery to the popliteal space, being traceable throughout, and being more severe at the part corresponding with the opening in the adductor magnus. In course of time the pain passed into the leg, and here some limited œdema was seen at the seat of pain, but not beyond. Similar pain came suddenly in the right axilla, and passed gradually down in the course of the brachial artery into the forearm, and here again a limited œdema occurred. He was treated with iodide of potassium, alkalies, and biniodide of mercury at various times, and in varying quantities, but without material effect upon the disease. Subsequently the right carotid artery was affected in a similar way. The symptoms pointed evidently to disease of an artery, probably inflammation of the fibrous coat; since the pain passed from the centre to the periphery, was in the course of the various arteries and was made intense directly the finger perceived the pulsation of the artery beneath it. Mr. Morgan had not been able to find any record of observation of symptoms. The patient is now in good health and has had no recurrence of the symptoms. He was shown to the Society.—Mr. HEATH said it was interesting that the arteries should have been inflamed and yet not blocked. He suggested that the patient had a tendency (possibly congenital) to disease of the bloodvessels; and asked whether there was any history of gout, in which disease there is a form of inflammation around arteries.—Mr. MCHARDY said that Dr. Buzzard and himself had examined the patient's retina, and had found the arteries to be only about one-third the size of the veins. The veins were not tortuous or distended, so that the arterial circulation seemed deficient. The arterial coats were not appreciably thickened.—Dr. TAYLOR asked whether any sphygmographic tracings had been taken. It would be interesting to know what influence an inflamed artery had on the pulse-trace.—Mr. HAWARD said the history of syphilis afforded the most natural explanation of the arterial condition; and the intermittency of the affection was rather in favour than against the theory of syphilis. He asked Mr. Heath whether arteritis was common, and if so whether clotting was a usual symptom of it. He had never met with it clinically.—Mr. HEATH agreed that arteritis was not a common thing clinically, but it had been laid down that in arteritis obstruction takes place.—Mr. HAWARD had never seen, in a large number of post-mortem examinations, any instance of clotting in an artery, but had met with arteries which showed old evidences of inflammation in thickening and opacity of the walls, and diminution of lumen. But of course he had seen inflammation in an artery set up by an embolus.—Mr. T. SMITH asked at what period of the case was the diagnosis made. He had never seen a case of primary arteritis during life. Mr. Savory had recorded a case of extreme diminution in the calibre of the carotid and other large arteries without clotting.—Mr. RUSHTON PARKER had very little doubt that in some instances arteritis led to plugging from blood-clot. Mr. Lister had recorded a case in the *Edinburgh Medical Journal* of gangrene of the leg in a child following measles. But acute arteritis seldom occurs except from traumatism. Ligature produces arteritis whether the coats be divided or not, and plugging results. He had seen cases where a rope pressing on the brachial artery had caused plugging, and another of severe injury with rupture of the brachial plexus and plugging of the subclavian.—Mr. MORGAN, in reply, said there was no history of gout. At no time was there any indication of plugging or impeded blood-flow in the affected arteries. Unfortunately no sphygmographic tracings were taken. The symptoms, and especially the extreme tenderness over the arteries themselves, were not those of neuritis. The diagnosis was made when one artery after another became affected.

Mr. T. SMITH showed a case of Nævoid Enlargement of one limb and the same side of the body. He had seen two other cases—one which he recorded in St. Bartholomew's Hospital Reports, of nævoid elephantiasis of one leg, with large venous sinuses about the nates, the main vein passing through the sciatic notch. The leg was bandaged and its size much reduced, but it became very painful, and the child died. The cellular tissue and skin of the limb were found to be much hypertrophied, and an abnormal system of veins passed up the back of the limb, emptying in the pelvis. The iliac veins were very large. The other case, a young lady of fourteen or fifteen, was less marked, and was treated by a tightly fitting elastic stocking. She is now twenty-six years of age. The present case, a boy, presents a similar condition of the right lower limb, and some nævoid stains about the chest. The leg was bandaged for a week, but it caused pain and tenderness and general failure of the health, so that the bandage (which proved so disastrous in the first case) had been left off, and it was intended to substitute an elastic stocking. Mr. Smith attributed the ill effects of the bandage to the disturbance produced on the general circulation by its pressure.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Recovery from Optic Neuritis.—Congenital Anomaly in Yellow-spot Region.—Blood-clot behind Iris.—Colour-blindness.

A SPECIAL meeting was held on the 7th inst., W. Bowman, Esq., F.R.S., President, in the chair, the main business being the presentation of a report of a committee upon colour-blindness, which was read by Dr. Brailey. At the close of the meeting a demonstration on the subject was given.

Dr. HUGHLINGS JACKSON showed a case ten years after recovery from Optic Neuritis. The patient came under care ten years ago for cerebral disease, seizures beginning in the right cheek, followed by right hemiplegia and temporary aphasia, and neuritis. The disease was due to syphilis, and under iodide of potassium recovery took place. The patient now complains of some numbness in two fingers of the left hand. His optic discs appear normal; one could not say from examining them that there had been neuritis. Vision too is normal.

Mr. WAREN TAY showed an infant, aged twelve months, who was brought to the London Hospital for weakness of its back and limbs. Suspecting some cerebral affection (congenital) the optic discs were examined with the ophthalmoscope. They were found to be healthy, but on the yellow-spot region of each eye was a conspicuous white patch of considerable size, with a brownish-red fairly circular spot in the centre. The conditions somewhat resembled those met with in the yellow-spot region in cases of embolism of the central artery. The changes are probably situated in the retina, and are possibly congenital. There were no signs of syphilis whatever; a sketch of the fundus of each eye was exhibited.—Mr. BRUDENELL CARTER suggested that the appearance was due to some opacity of the connective tissue around the fovea centralis, leaving a space through which the choroid was visible.—Mr. TAY said the yellow spot itself certainly seemed to be healthy. The condition had not altered during the six weeks it had been under observation.

The PRESIDENT showed for Mr. Power a case of Hæmorrhagic Clot behind the Iris, the clot having remained unaltered for some months. The humours were clear, but there was a dull reflex from the fundus suggestive of deeper effusion. Mr. Bowman remarked that blood-clots in the eye often remained unchanged for many months—e.g., in diabetes. In this case the iris looks normal. The eye is very nearly blind.

The Report on Colour-blindness was then presented for a Committee of the Society by its Secretary, Dr. W. A. BRAILEY. By the aid of sixteen colleagues 18,088 persons have been examined, of whom 1657 were females. The average percentage of colour defects among these latter was ·4, that of the males being 4·76, the pronounced cases only among males being 3·5 per cent. Certain classes of persons show an exceptionally high percentage of colour defects. The most striking in this respect are deaf-mutes, among whom every fifth child is defective. The average is also higher than normal among members of the Society of Friends, especially among those belonging to the poorer classes. It is distinctly high among Jews, and the forms of colour-blindness occurring among these are very pronounced. There is also observed a diminution in the percentage of colour-blindness as we ascend in the social and educational scale. For example, at Eton (769 boys) the percentage of pronounced cases, which are the most reliable for purposes of comparison, is 2·46. Among medical students and sons of medical men (435 persons) it is 2·5. In middle-class London schools (2671 boys) it is 3·48. In the Metropolitan police (4932 men) it is 3·52. Among poorer schools in London (1729 boys), 3·87. There appears to be no excess of colour defects among lunatics, or in town, as distinguished from rural populations. They are perhaps greater in Ireland than in England. All the pronounced cases reported (red and green blinds), not only make mistakes in the matching of coloured wools, but are unable to distinguish the colours of red and green lights; though sometimes, when they are contrasted side by side or in rapid succession, they are enabled to guess them by the fact that with equal illumination one appears to them always brighter than the other; but if their brightness and distance be unknown they are utterly unable to distinguish between them. Certain remarks were added by Dr. Brailey as to (1) the causation of colour defects, and (2) as to the mode in which the red- and green- blind see these colours. He attributes colour defects in some cases to a congenital physical defect, either in eye or brain, occurring as an accidental variation from the normal structure. When once existing it is capable of being transmitted to descendants. In other cases he thinks that they may arise, more especially the slight forms, from defective education in colours in infancy. This might account for the superiority of the female sex in respect to colours. Though brought up in very early life under the same circumstances as males their different tastes lead them to a greater study of colours, which will be facilitated by their more rapid mental development, especially in the observing faculties. It would also account for the high percentage exhibited by the deaf and dumb, and to some extent for that of members of the Society of Friends. It would also be compatible with a greater prevalence of colour defects among the poor. The third factor, which is by no means an unimportant one, is intermarriage. He is strongly of opinion that among Jews, and to a less degree among Friends, intermarriage during generations has strengthened the defects existing among them not only in number but in degree. In connexion with this it is important to notice that red-blindness, which he considers a more aggravated form than green-blindness, is especially prevalent among Jews, and, to some extent, among Friends also. He suspects an unduly high average of colour defects among the children of those working in colours, such as artists, dyers, &c., though he has as yet not collected sufficient evidence to establish the position on a statistical basis. With regard to the question as to what those blind to red and green see in place of these colours, he thinks that they appear to them as shades of grey, either pure or mixed, with a little of yellow. The completely green-blind probably sees pure *green* as a pure grey of the same shade. *Red* he sees as a dull yellow-brown, of a shade similar or slightly darker than the red is to a normal eye. Therefore he will more commonly match green with grey and red with yellow-browns, or with a green that is slightly yellowish. The completely red-blind sees *green* as a grey tinged with a little yellow, but of similar shade. He sees *red* as a very dull yellow-brown of much darker shade than the red is to a normal person. Therefore he will match red with a much darker yellow-brown, or with a much darker slightly yellowish-green. He will match green with grey less often than the green-blind. He thinks that in red and green blindness there is also a slightly defective appreciation of all colours, so that all pale shades are liable to be confused, especially at a distance, or by artificial or deficient light.—Mr. FROST mentioned a fact bearing on the hereditary transmission of colour-blindness. The father, a draper, was so colour-blind as to be obliged to mark the colour of all his goods. Of his seven sons, six were known to be colour-blind; but none of his three daughters were; one of them, however, has a son who is completely red-blind; and being a jeweller is unable to distinguish between rubies and emeralds.—The PRESIDENT was not previously aware of the prevalence of colour-blindness in the Society of Friends. Dalton was a Friend and he mentions a brother of his who was also colour-blind. It was also interesting that among this society both sexes seemed equally prone to the defect. The influence of education had been also seen in reports in other countries. As the object of this inquiry was to induce the Board of Trade to institute examinations of officials concerned in signalling, &c., the value of a report based on 18,000 cases was great. It was interesting to find its results agree with those obtained elsewhere, and especially with the more recent investigations; for in Norway and Denmark recent observations (made under improved experience) had not tallied with earlier ones. There appeared to be but few cases in which only one eye was colour-blind. We are still only at the opening of the inquiry upon the nature of colour-blindness.—Mr. BRUDENELL CARTER thought that all cases of monocular colour-blindness would escape notice under the present plan of examination. When one considers that anisometropia is not uncommon it seems likely that many cases, especially those which are hereditary, may be met with. He expressed the great debt which the Society and the public owed Dr. Brailey and his coadjutors for this arduous investigation; of its importance there could be no question when one considered that one railway company (the London and North Western) alone employs about one thousand engine drivers, of whom forty-five must be colour-blind. This would illustrate the great perils incurred, and suggested that many accidents may be due to this hitherto unknown and unappreciated cause. It was most important, then, to get legislative recognition of the subject.—Mr. M'HARDY had found that engravers were often colour-blind, and some had not taken to engraving for this very reason. He asked what was the highest percentage of colour blindness amongst any particular class of the Friends' children. On the Connecticut Railway at least one per cent. of the *employés* was found to be colour-blind; many such get discharged from work on account of mistakes attributed to carelessness, &c. He referred to the case of a collision in Norfolk Harbour, U.S., where there was cross-swearing as to the colour of the lights; when the pilot was found, three years subsequently, to be colour-blind, and incapable of distinguishing between red and green lights at an ordinary distance. He was accordingly discharged from his office, as were many other pilots, who were found to be similarly affected. In reply to Mr. Carter, he said that wood-engraving often runs in families, but sometimes one of the family is a water-colour artist.—The PRESIDENT remarked that a person with artistic aptitude, but colour-blind, would naturally devote himself to etching or engraving.—Dr. BRAILEY replied, the substance of his remarks being given above.

The Society then adjourned.

Reviews and Notices of Books.

How to Use the Forceps. By H. G. LANDIS, M.D. New York: J. B. Treat.

THIS little work is divided into two parts. The first treats of the anatomy of the pelvis and the mechanism of labour, the second of the forceps and its application. The pelvis is described as consisting of two canals partially separated at the inlet, but identical at the outlet. "These canals converge from above downwards, and are mutually curved from before backwards. Their direction is therefore somewhat spiral. The calibre of each canal is that of the fœtal head, therefore the head may descend in either canal, and will follow a spiral course in so doing." In accordance with this view of the pelvis the mechanism of labour is briefly explained as well as the principles which should guide us in the application and use of the forceps. The author recommends the use of the long forceps, but in their introduction and application regard is had to the head and not to the pelvis, for the blades should grasp the head in the biparietal diameter. The author is opposed to the employment of the so-called leverage movement to effect delivery, and employs traction only, and this he applies after a method of his own. He disapproves of the manner usually recommended in text-books of making traction. He maintains that pulling on the handles of the forceps drags the head not in the axis of the pelvis, but against the symphysis pubis. In order to avoid this, he recommends that the handles should be held by one hand, so as to grasp the head firmly, and that the other hand should be "placed so that the ball of the thumb comes over the lock, while the index-finger rests upon the upper arm of one blade, and the middle finger upon the other. Now, while the right hand holds the handles almost at rest, the fingers of the left push the blades so as to move them and the contained head downwards, backwards, and a little to the left of the median line. Secondly, while the fingers are pushing downwards in this way, we may also make use of them as a fulcrum, and by elevating the handles cause the blades to move in an opposite manner, but care must be taken that the force thus applied by the right hand is not enough to overbalance the downward pressure of the left, else we will merely extend the head without propelling it." The above will give some idea of the method of using the forceps recommended by the author. The work contains much that is original, and will repay a careful perusal.

The Natural History of Cranes. A Monograph. By the late EDWARD BLYTH, C.M.Z.S. Enlarged, with numerous Illustrations by W. B. TEGETMEIER, F.Z.S. Pp. 91. London: Horace Cox. 1881.

THIS prettily-illustrated work contains a zoological account of all the known species of cranes. It is founded on a monograph by the late Mr. E. Blyth on the Gruidæ, but great additions have been made to it by Mr. Tegetmeier, which add much to its interest. The cranes, as a whole, are a very well-defined group, and some of them exhibit intelligence of a kind that is rare amongst birds. Their name (crane—grus—*γέρανος*—sárrás—kárrunck, and the like, in different languages) is almost always onomatopœic, and indicative of the loud trumpeting sound they can emit. They are somewhat formidable animals when wounded, being able to transfix the walls of the abdomen with one stroke of their powerful and pointed bill, or to rip it open with their recurved claws. It is stated that when the bird is wounded, the best way to avoid its attacks is to present the muzzle of the gun as it approaches. It will fix its bill in the orifice, and may then be destroyed without danger. Several of the species migrate, the flock assuming a V-shaped form and flying at a great height. The members of the group are very widely distributed, being found everywhere except in South America, the Malayan and Papuan Archipelago, and the scattered islands of the Pacific. At one time they were common in the fenny counties of England. They appear to be entirely vegetable feeders. Mr. Tegetmeier observes that old Æsop's fable of the stork being captured in the evil companionship of the cranes, and being condemned to death for thus associating with notorious grain-plunderers, indicates that he knew well enough the two kinds of birds, far better, indeed, than the renowned prince of mediæval painters, who commits the zoological mistake of introducing cranes instead of storks into his world-famous cartoon of the miraculous draught of fishes. The cranes pair for life, and some, as the American white crane, propagate whilst still in the plumage of immaturity. The nest is built in swamps or lagoons, and most interesting accounts are introduced from the notes of the late Colonel Tickell of the love-making of the Grus antigone, and of Mr. Wolley upon their nesting, which he took infinite pains and trouble to inspect. The Gruidæ are divided into two groups, Balearica and Grus, the former being the crowned cranes of Africa; the latter include the Stanley or paradise crane; the damoiselle crane, a beautiful specimen of which is now, or was very recently, in the Zoological Gardens; the wattled crane; the white-naped crane, common in Japan, and represented on many of their ornaments; the Asiatic white crane, and others. Mr. Tegetmeier places in an appendix some observations he has made upon the convolutions of the trachea in birds. This tube is remarkably developed in the Gruidæ, forming convolutions which are partly lodged in a groove of the keel, or sternum, and partly occupy the space between the diverging limbs of the furculum. He is of opinion, and he supplies many facts in support of his opinion, that the elongation of the windpipe, and the resulting twisting and convolution if it is much elongated, are connected with the deepness of the note and resonant character of the voice. Several woodcuts illustrate the dissections he has made. The work will be read with interest by every zoologist and sportsman.

MR. ARTHUR FLINT, L.R.C.P., of Westgate-on-Sea, has been elected to the Board of Guardians and Sanitary Committee of the Isle of Thanet Union.

THE LANCET.

LONDON: SATURDAY, APRIL 23, 1881.

LAST week, in considering the question "Why may we not meet professed homœopaths in consultation?" we were driven to the conclusion that we cannot consult with consistent homœopaths (if for no other reason) because their notions of pathology and therapeutics are fundamentally different from and antagonistic to ours; and that we cannot consult with professed or nominal homœopaths, though they may occasionally practise according to the principles of scientific medicine, because they retain a name that, in their case, possesses no logical meaning, and is used for sectarian purposes. From this conclusion we feel convinced neither good sense nor good faith will attempt to find any way of escape. If homœopathy be not *exclusive*, as HAHNEMANN asserted it should be, it has no claim to be regarded as a special method. Homœopathy is essentially either a complete and formal system of therapeutics, or it is a mere assumption, and at the utmost a provisional hypothesis capable of limited and exceptional application. Neither the oft-quoted but equivocal assertion of HIPPOCRATES, *διὰ τὰ ὅμοια νοῦσος γίνεται, κ.τ.λ.*, "by similar things disease is produced, and by similar things administered the sick are healed of their diseases"; nor the less known dictum of PARACELSUS: "Inde sequitur simile per simile curari," affords any real support to HAHNEMANN'S notions of the nature of disease and of the selection of appropriate remedies. Even if the statements we have quoted were more precise and explicit than they are, their value would be purely historical, and in no sense or degree scientific. The allegation of PARACELSUS is only a part of his strange and erroneous doctrine of the Chemical Triad; and there are good reasons for believing that the treatise from which the support of HIPPOCRATES is drawn may not be genuine. However interesting, therefore, the testimony of these authors may be historically, it is worthless so far as it has been adduced to give warrant and authority to HAHNEMANN'S *Laws*. Of still less scientific value, in this connexion, are the conjectures of ANAXIMANDER regarding the nature of primitive matter, or ANAXAGORAS' doctrine of *ὁμοιομερῆ*, or DEMOCRITUS' theory of atoms. The truth or fallacy of homœopathy as a method of pathology and therapeutics cannot be established by appeals to the speculations of ancient philosophers or physicians. The claims of homœopathy—that is, of Hahnemannism—have been tried at the bar of scientific ctiticism, and have, in every instance and degree, been disallowed. The so-called law of similars and the law of dynamisations have been refuted by a general consensus of scientific opinion, and homœopathy has been deliberately held to have no point of contact with scientific medicine; consequently the practitioners of scientific medicine have, as a body, refrained from professional intercourse with those who practise or pretend to practise homœopathy. Physicians have, for the most part, been especially scrupulous in the observance of this rule of professional etiquette. As much cannot, however, be said for surgeons. Of late years there has been a growing laxity on the part of some surgeons in this matter. The explanation usually adduced is that whatever objections may be urged against homœopathy as a system of therapeutics, so far as it relates to diseases falling within the physician's domain, these objections cannot apply to surgical affections that require operative aid. This explanation is plausible at first sight, and might suffice if surgeons of the present day stood at the same low level as their predecessors six hundred years ago; but it is specious and not altogether honest now. In the thirteenth century surgical operations were generally performed by persons so ignorant of anatomy and medicine, that GUY of CHAULIAC stigmatised them as mere *mechanics*. Before WILLIAM SALICETTI, by his two works, "Chirurgia Magna" and "Chirurgia Parva," lifted surgery out of the low depths into which it had been sunk by the priests and monks, all who performed surgical operations, whether men or women, were compelled to undertake to limit their labour to *handiwork*, and not to give advice or administer any internal remedy without the permission of a physician. We have now changed all that. As no surgeon is now content to be looked upon as an artisan, it is difficult to understand how anyone claiming rank as a skilled and educated surgeon can agree to consult with a homœopath. To do so almost implies that he is willing to enter upon a similar undertaking to that demanded six centuries ago. The practice of surgery is no longer confined to the performance of the operation, but includes all the difficult and complicated details of the after-treatment. In the management of this much strictly medical knowledge and skill are often required. Indeed, the success of modern surgical practice as compared with that of former times lies, mainly, in the care and attention given to many matters previously deemed to be outside the sphere of practical surgery. Unless a surgeon, therefore, is prepared in the presence of such complications of operations as pyrexia, pneumonia, bronchitis, and pyæmia to stand aside and see his patient treated according to views of his homœopathic colleague, and perhaps sacrificed thereto, he must, quite as much as the physician, refuse to act in conjunction with a professor of homœopathy. The late Sir BENJAMIN BRODIE in a letter published in *Fraser's Magazine* in September, 1861, said, "To join with homœopathists in attendance on cases of either medical or surgical disease would be neither wise nor honest. The object of a medical consultation is the good of the patient; and we cannot suppose that any such result can arise from the interchange of opinions where the views entertained, or professed to be entertained, by one of the parties as to the nature and treatment of disease are wholly unintelligible to the other." In this just opinion all thoughtful persons must acquiesce.

◆

THE Metropolitan Medical Association is in a state of considerable activity. And when an association composed of very energetic men is in a state of activity, something of importance may be expected to result. We have only to mention the principal names representing this Association—The Right Hon. JAMES STANSFELD (Chairman), Sir CHARLES TREVELYAN, Sir RUTHERFORD ALCOCK, Sir SYDNEY WATERLOW, Sir FOWELL BUXTON, and Mr.

SAMUEL MORLEY—to assure our readers that there are life and purpose in this movement. A few weeks ago we noticed a meeting at Croydon in furtherance of the objects of the Association. Now, another is announced, the treasurer, Mr. HAMILTON HOARE, being in the chair. Mr. HOARE said the object of the Association was to benefit the working classes—(1) by lessening the expenses of sickness; (2) by obviating the necessity for doctor's bills; (3) by providing them with the best kind of medical advice and medicine which it was possible to get; and (4) by saving them entirely from the miseries and evils which had to be experienced when, for want of a better system, medical aid and medicine had to be sought for at the out-patient department of a London general hospital.

It is certainly most desirable that the working classes should be encouraged to take much more thought than they do about provision against the day of sickness and accident. Much of the disease that accrues to families is not accidental. It may be reckoned on; it should be anticipated. The sicknesses of children—measles, whooping-cough, scarlet fever, and, in negligent families, small-pox; diarrhœa, and the diseases of the period of teething and of growth; colds and the diseases of winter—to say nothing of constitutional ailments and weaknesses,—constitute half the care, and lead to half the work, of an intelligent medical man. A rich man can command the best advice in any emergency. He can go to a warm climate, or take a sea voyage. He has a number of resources for curtailing and curing disease; but when disease overtakes a working man, or his wife or child, he has to rely on a neighbouring doctor and on his good medicines. The object of the Metropolitan Medical Association is to intensify in the working man the sense of responsibility for meeting the incidence of sickness and to help him to make good arrangements beforehand. We do not wish to say anything in discouragement of such a movement. The almost universal distribution of medical clubs and provident dispensaries makes it now most easy for any thoughtful working man to secure good medical attendance for himself and family in any emergency. Far better arrangements still could be made if working men would take the matter into their own hands and come to personal terms with a medical man in their own immediate neighbourhood. Nobody knows better than such working men that good doctors and good drugs should be paid for; that the "workman is worthy of his hire"; that medical wisdom and dear medicines are not to be got in the first "shop" for sixpence. Many of the so-called provident dispensaries even are very far from perfect in their provision for retaining the best doctors. Some of them go on the principle of selecting a stranger, generally a young man, at a low salary, and exacting from him an unconscionable amount of work. A correspondent, whose letter we insert to-day, disappoints us by his account of the medical arrangements of the Provident Dispensary system in Manchester. A single doctor is appointed; his name and private address are advertised, and patients of other doctors are canvassed and pressed to join the dispensary. What is the good of such work as this? What is the benefit of asking a respectable working man, paying his bill creditably to an adviser of his own choosing, to leave his trusted doctor to pay a small and inadequate subscription to a dispensary system he does not need? Further, we have before had to complain of the tendency in these large movements to offend and injure medical men by admitting well-to-do people to the benefit of arrangements which are only allowable in the case of persons of very limited means. We should like some assurance that these grave faults are to be avoided in the metropolitan scheme, which seems to us a little too paternal and patronising towards the working man. If men like Sir SYDNEY WATERLOW and Sir RUTHERFORD ALCOCK, both prominently and honourably associated with the London hospital system and with this Provident movement, would use their influence fully, it should be quite possible to have an Out-patient Department to which a respectable working man could repair on suitable occasions with as little loss of self-respect as to the In-patient Department. We cannot see why it should necessarily be associated with "great miseries and evils" other than those incident to the very existence of sickness and poverty.

THE discussion on desquamation after scarlet fever, which has lately occupied a portion of our columns, will repay attention. As part of the larger question of the diagnosis of scarlet fever, it is of great interest. There is hardly any disease in regard to which diagnosis is at once so difficult and important as scarlet fever. All authors agree in saying that almost every prominent symptom of it may be wanting. All the symptoms of the earlier stages may either be absent or may be overlooked—sickness, sore-throat, and rash. And even the temperature, judged by one or two observations, may be below 100°. All authorities describe, and all practitioners are familiar with, cases in which no suspicion of the disease exists until the occurrence of desquamation, in circumstances which leave no doubt that it is only a part of scarlet fever. But surely desquamation itself is also a most variable process, and, as our correspondent "Vigilans" observes, is so variable as to excuse a good deal of the variety of opinion on it, which undoubtedly exists. It may be almost entirely absent, it may occur out of proportion to the amount of rash, it may be long delayed, or it may extend over a very variable period. The recent correspondence was based on the case of a boy at a large public school near London, whose scarlet fever was detected only by close observation, the amount of rash being small, and the whole attack unusually light. The medical officer of the school gave his sanction for the boy returning home three weeks after the attack, who never had any sign of desquamation. The father having other children at home during the Christmas holidays who had not had scarlatina, naturally felt afraid, and wisely (we presume with due precautions for the boy and others) removed him to an infirmary specially intended for such cases. Between two and three weeks later, and six weeks from the commencement of the attack, when the boy should have returned to school, he was found by a practitioner to be peeling. The medical man of the school considered the peeling to be unconnected with the attack which he had at school, and to be due to eczema. The father of the boy associated it with the attack that had been so well diagnosed at school, and saw in it a justification of his caution in not allowing his son to return home. The majority of authorities will be disposed to agree with Dr.

DAVID PAGE, that patients recovering from scarlet fever may have their desquamation much deferred, and that certainly they are not desirable as members of society for at least eight weeks. This is very hard, especially in cases where the disease is slight, where there is no sense of illness and but slight or no appearance of desquamation, but it is sound doctrine. The precautions may be excessive, but the case is one for great caution. Still it must be admitted that even among authorities there has been a variety—not to say looseness—of teaching which goes far to explain, especially in connexion with the acknowledged variations in the process, the view taken by the medical officer of the school. Let us notice only a few that are at hand. TROUSSEAU says, "Desquamation in scarlatina is not very well understood by the majority of physicians." He instances a case in which, though at the seventy-second day, it was still going on. TROUSSEAU would have been apt to regard even HEBRA as unsound, for HEBRA speaks of desquamation as ending at the "end of the third week." Dr. J. LEWIS SMITH, a very good observer, of New York, speaks of desquamation as succeeding the disappearance of the eruption and occupying "several days." Mr. MALCOLM MORRIS says it begins in the latter part of the second week, but may commence as the rash fades, or not until the end of the sixth week. Dr. BRISTOWE says the period of desquamation is of various duration. "It is sometimes completed in one or two days, not unfrequently extends over a week or two, and occasionally is prolonged for several weeks." Whether difference of opinion is sound excuse for difference in practice, the variety in the process itself and the occasional instances in which it is deferred indicate the safety of a rule of exclusion of at least six weeks, and if possible of eight. Parents and patients will often rebel against this hard doctrine, but, considering the gravity of the disease, it is a safe one for medical men to hold. Our correspondent of to-day, "Vigilans," reminds us that all desquamation is not scarlatinous. He describes one case in which it seemed to result from the administration of turpentine for hæmaturia. This suggestion is one to be remembered, when sanitary law and professional duty in connexion with desquamation are often both delicate and difficult.

◆

THE office of Coroner for the Central Division of Middlesex being again vacant, it becomes necessary to call upon our professional brethren to use all their influence in support of a medical coroner. The late Mr. WAKLEY, counted it among the triumphs of his energy to have secured this office for the profession, and to have been the first medical coroner. Dr. LANKESTER was a worthy successor, and Dr. HARDWICKE has justified the trust reposed in him. On this occasion, perhaps the last when the appeal will lie to the freeholders of the district, there is, we believe, to be a very determined attempt to recover the post as a prize for the legal profession, which has already more than its share of positions commanding both emolument and prestige. This consideration alone should induce members of the medical profession to enter into the contest with unwonted alacrity and earnestness. There are, however, better and higher reasons for urging instant action in the matter. Abundant indications have recently been apparent tending to show that the rights and interests of the profession, as medical witnesses and practical inquirers for "the cause of death," are about to be invaded. Elsewhere we draw attention to a question relating to fees for post-mortem examination in cases where the medical evidence given privately to the coroner obviates the necessity for an inquest. Under the plea that the medical man is not required to go into court, and that his report is communicated in writing, the fee for his opinion is to be reduced by fifty per cent., and rewarded by half-a-guinea instead of a guinea! This paltry economy is not unnaturally regarded as an insult by the medical practitioners of Kent. If the recognition won for the profession in Middlesex by the late Mr. WAKLEY, to whose endeavours the remuneration of medical witnesses was due, is now sacrificed, the effect on the question of fees in general cannot fail to be most disastrous. Medical and scientific knowledge is an undoubted advantage, if not a positive necessity, to a coroner. It saves the ratepayers' money, and prevents many miscarriages of justice. We will not say more on the subject of the election at the present moment, but no time should be lost by the medical practitioners of Central Middlesex in exerting their influence to secure the return of a member of their own cloth.

Annotations.

"Ne quid nimis."

THE LATE EARL OF BEACONSFIELD.

THE protracted illness of Lord Beaconsfield has terminated fatally. The age of the noble lord rendered this issue probable from the outset; and although desiring to welcome and cherish any hope which could be suggested, we have not been able to disguise the circumstance that throughout the conditions have been unfavourable to recovery. Those who closely watched the health of the deceased gentleman, during the last fifteen years particularly, cannot fail to have noticed the struggle which has been maintained by the mind against, and, to some extent, at the expense of, the body.

While Mr. Disraeli sat in the House of Commons his life was an almost continuous effort. His imperturbable bearing, his habit of emotional self-restraint, his almost uniformly placid style of delivery—artistically, and always as the result of purpose, never involuntarily, varied by lighter and brighter passages of elocution,—were the fruits of effort. The statuesque posture, the motionless face, the abstracted or seemingly indifferent manner, which the superficial observer mistook for indications of a constitutional lack of sensibility, were, in truth, tokens of the intensity of the emotional nature they disguised. Lord Beaconsfield was a man of profoundly deep feeling and a highly sensitive temperament, but, with an indomitable will habituated to self-control, the customary expressions of such feeling as he possessed were interdicted. For example, in place of movements of the ordinary excito-motor type, the noble lord's physical habit was, in the later-middle period and towards the end of his career in the Commons, characterised by slight and seemingly automatic, but really conscious, acts of the slightest kind often repeated. It was very curious and exceedingly interesting to study these movements from the psychological standpoint. Under ordinary circumstances Mr. Disraeli would sit for long stretches of time during the violent or terribly irritating attack of a political opponent, with nearly closed eyes, as though asleep.

When the onslaught waxed furious he would, as though with all-engrossing intent, fix his gaze at the toes of his boots, moving them slowly so as to bring all points under observation. If the taunts or reproaches hurled at him were of so grievous a nature as to make any other man furious, he would straighten himself and brush some particle of dust from the front of his buttoned frock-coat, or from the sleeve of his left arm. Then he would examine his nails, and as a climax, when few statesmen so assailed could avoid some token of emotional restlessness, he would, perhaps, take out his single eyeglass, and, fixing it firmly, look for an instant at the clock in the front of the gallery opposite Mr. Speaker, dropping the glass with one quick elevation of the eyebrow. This last-mentioned trick being the only part of a series of actions which, though familiar to his observer, was never a mere matter of habit. Probably, and it is worth noting in reference to the recent incident of his approaching the Ministerial bench in the House of Lords after the division at the close of the Candahar debate, the noble lord was less a man of *habit* in the true sense of that term—i.e., as implying the relegation of large classes of actions to the subconsciousness to be performed automatically—than the average brain-worker. The fact is interesting as throwing light on the type of his physico-mental constitution, and as illustrating the character of the strain which the life and enterprise of the deceased statesman imposed on his mind-power.

The long illness of the Viscountess Beaconsfield caused Mr. Disraeli an intensity of mental suffering which perhaps few, if any, of his most intimate friends adequately appreciated. He was not a man who wore his heart—and it was truly a great heart—on his sleeve, or found relief in the semblance of sorrow. The embarrassing political circumstances under which Mr. Disraeli first succeeded to the Premiership of the late Earl of Derby almost exhausted his powers. During the debates which preceded the Disestablishment of the Irish Church, he went through an amount of mental toil severely trying a constitutionally weak muscular system, a fact which was not sufficiently recognised. Probably few statesmen have suffered more, or surmounted greater physical obstacles, than Mr. Disraeli suffered and surmounted on the day preceding and during the night of the delivery of his great speech on Mr. Gladstone's famous Resolutions immediately before the Derby-Disraeli administration resigned. Then came a period of less strain, in which those who closely and anxiously watched the right hon. gentleman were rejoiced to observe a marked and progressive improvement in his general state with indications of a new storing of mental and nervous strength. Probably Mr. Disraeli was to all practical intents as well as he had been, for a decade at least, when he took office as Prime Minister in 1873. The cares and toil of a purely Ministerial life he might long have endured without any serious loss of strength, but the physical exhaustion consequent on long sittings in the Commons told heavily against him, and it would have been better had he been able to bring himself to accept the relief likely to be afforded by removal to the House of Peers the second time Her Majesty graciously pressed the proposal upon him. On the first occasion, as is well known, Mr. Disraeli, ever the most devoted and delicately affectionate of husbands, obtained leave to place the coronet on his wife's brow which had been intended for his own. It was, practically, too late when Mr. Disraeli became Earl of Beaconsfield to prolong a valued life by the means adopted. Speaking now freely, we believe the deceased statesman would have lived longer if he had *not* thus late retired to a scene of comparative quiet, upon which he ought, in the interests of his health, to have entered when the Queen urged him to do so some years before! As it was, Lord Beaconsfield was deprived of his accustomed mental stimulus at the precise moment when he most needed it; and although his immediate personal feelings were those of relief, the physical ease was purchased at too great a price.

From the outset of the last illness the case was, in our judgment, hopeless, unless the higher cerebral centres of the nervous system came to the relief of the lower. The bronchitis was not a "complication," but an integral part of the gouty affection. It was, in the history of the noble lord's life, one of the earliest indications of the gouty diathesis, the next in order of time being slight gastric and intestinal irritation. It must ever be a source of regret that Lord Rowton, who alone had stood in close personal relations with the deceased gentleman during many recent and trying years of his life, was unavoidably absent during the first and only hopeful stage of his illness. It is also, we think, unfortunate that Lord Rowton did not see the noble lord until four days after his return, whatever may have been the fact as to Lord Beaconsfield's own wishes in the matter! It is, again, we think, to be regretted that Her Majesty's graciously expressed desire to visit the noble lord was not carried into effect. We must be excused for giving expression to these regrets—they are essential to the professional view we take of the illness. In the end, death occurred, as it must have been expected to occur, after a temporary revival of the failing powers of vitality such as is usually manifested in cases of the class—in the closing days of a life lived, mainly, by mental energy or mind-force. The apparent improvement which took place towards the end of last week, and which was attributed to "the weather," and seems to have excited false hopes, should scarcely have proved misleading.

Profound regret fills every mind, wholly irrespective of the political view which may be taken of Lord Beaconsfield's life and worth as a statesman. He died full of years and honours, but his departure will leave a vacant place in the Legislature, in society, and in the country, which cannot soon be filled.

FEES FOR POST-MORTEM EXAMINATIONS.

ATTENTION has been publicly called to the remuneration awarded to the medical man who conducts a post-mortem examination on a coroner's order. At present the fee stands at two guineas, of which one moiety is supposed to be a sufficient fee for the examination itself, and the other for the report or evidence supplied upon that examination. It cannot be questioned that this is far from being adequate. The careful conduct of a post-mortem examination itself requires the devotion of a large amount of time, and the application of much special knowledge, and it is surprising that no attempt should have been made to fix the remuneration for such highly important service to the State at a much higher rate. We are even more surprised to hear of the resolution passed at the Kent General Sessions to reduce the fee by one-fourth in such cases where a report only is required, and no evidence in the coroner's court called for. On narrow technical grounds, and in a spirit of false economy, such a resolution might perhaps be justified; but it has been overlooked that the labour to the medical man is just as great; his expenditure of time almost as much, whether he simply furnishes a report or gives his evidence orally, whilst the written report obviates the necessity of unnecessarily multiplying inquests, and is thus a saving of much expense. Accordingly the action taken by the medical practitioners of the Greenwich district in refusing to submit to the new resolutions is one which will be appreciated by the profession throughout the country. It is only by such action that they can bring home to the authorities the fact that the number of inquests is controlled by the reports furnished by the medical men, and it will, it may be hoped, lead eventually to a rescinding of the obnoxious resolution. Unfortunately at present this does not seem to be the opinion of the magistrates of the district, for they have ordered that in twelve cases where inquests might have been avoided had a report been sent in, a sum of 10*s.* 6*d.* be deducted from the coroner's bill in each case—a proceeding which is certainly not calculated to get over the difficulty! A good effect will be produced by the business if it lead to the whole question of remuneration for post-mortem examinations in medico-legal inquiries being reconsidered, and coroner's law being revised in a manner which shall recognise more liberally and justly the extreme importance of the part taken by the medical man in these grave and difficult matters.

THE SALIVARY GLANDS IN RABIES.

THE condition of the salivary glands in rabies both in the dog and in man has been investigated by Dr. A. Elsenberg of Warsaw. Singularly few observations on the point are on record, in spite of the significant fact that the saliva is the chief vehicle of the infection. Nepveu found in one case a considerable small-celled infiltration of the interstitial tissue of the gland. A similar alteration was also found by Coats, who also described as a characteristic feature the accumulation of small round cells in the neighbourhood of the veins. Elsenberg, who seems to be ignorant of the investigations of Coats, has examined the salivary glands from twelve dogs and two men affected with the disease. The results have been published in the *Centralblatt für Med. Wissenschaften.* In the dog the most striking changes were found in the sublingual and submaxillary glands. The former were slightly enlarged, greyish-red in colour, with a smooth section, presenting here and there an indistinct appearance of acini. Microscopically the interstitial tissue was infiltrated by small round cells, with one or several nuclei, apparently identical with pale blood-corpuscles. The infiltration was greatest around the ducts and around the medium-sized veins in the hilus of each acinus, and gradually lessened towards the periphery, while in the hilus of the gland itself it was entirely absent. In many places the infiltration was so extensive as to resemble a point of suppuration. In the interacinal tissue the infiltration was far slighter. The "fixed cells" of the interstitial tissue were slightly enlarged, but showed no indication of multiplication. The bloodvessels, especially the small veins and capillaries, were much dilated, and the distending blood contained a large proportion of white corpuscles, which were in part diffused among the red corpuscles and in part were aggregated against the side of the vessel. The epithelium of the alveoli was unaltered, the secreting cells contained a granular mucoid substance, while the nuclei were enlarged. The peculiar crescentic cells were enlarged to such an extent as to occupy two-thirds of the lumen of the alveoli, and their nuclei were increased in number to two or three times the normal. Besides these alterations, the glandular alveoli contained an inconsiderable number of small round cells like the leucocytes which thronged the interstitial tissue. Very similar changes were found in the medium-sized ducts. Small round cells, passing through the wall, had raised the epithelium, separated individual cells, and penetrated into the lumen of the duct. A similar infiltration of small round cells was observed around and even within the nerve ganglia. Changes similar in character, but slighter in degree, were found also in the sublingual gland. The orbital glands of the dog belong to the same category of glands, but were in each case very little changed. In the three salivary glands the changes above described were always to be found in greater or less degree. The parotid gland, however, showed only slight changes in four of the dogs. The small celled infiltration of the interstitial tissue was considerable. The glandular cells were a little enlarged, somewhat granular, and contained two or more nuclei. In man the parotid gland was always found healthy. The changes in the submaxillary gland were always slight, being confined to a small celled infiltration of the tissue around the ducts and middle-sized veins. The most intense changes were found in the sublingual gland, and were exactly similar to those described in the dog, although less intense in degree. These changes point to the pathological process, which we call inflammation, to be ascribed to an infectious material circulating in the blood, and excreted by the salivary glands. Although the submaxillary and sublingual glands present such intense changes, the mucous glands at the base of the tongue are seldom altered, and hence it is conjectured the specific infectious material is to be found in the saliva alone. The salivary glands rarely present changes in other diseases, and no alterations have ever been found in the dog in any other disease than rabies. Hence their presence in any given case would constitute very important corroborative evidence that the disease from which the animal died was really rabies. The only possible fallacy would arise from the circumstance that certain alkaloids—nicotin, pilocarpin, and muscarin—cause changes which are somewhat similar, but they are so trifling in degree that little error is likely to arise from this source. But in man the changes in the glands are far too slight to be of diagnostic importance, and seem to be met with in other infectious diseases.

SENIOR WRANGLERS AT CAMBRIDGE AND MEDICINE.

IN our last issue we announced that Mr. Donald M'Alister, the senior wrangler at Cambridge in 1877, had been admitted to the degree of M.B. It is just one hundred years since that the two sons of Dr. James Ainslie, a distinguished physician at Kendal, graduated as senior and second wranglers in the Mathematical Tripos of 1781. The younger son, Henry, was senior. He afterwards graduated in medicine, became a Fellow of Pembroke College, and, commencing the practice of his profession in Cambridge, was elected physician to Addenbrooke's Hospital. He subsequently settled in London and became one of the physicians to St. Thomas's Hospital. The elder son, Montague Farrer Ainslie, was bracketed second wrangler with Law, afterwards Lord Bishop of Bath and Wells. In 1815, the year in which Sir Thomas Watson graduated as tenth wrangler, a son of the senior wrangler of 1781 obtained the eighth place, and was afterwards for forty-two years Master of the college of which his father had been a Fellow. Bickersteth, the first Lord Langdale, who was senior wrangler in 1808, relinquished the study of medicine for the more lucrative and ambitious pursuit of law. These, as far as we are aware, are the only senior wranglers who have devoted themselves to medical studies.

WESTMINSTER HOSPITAL.

SEVERAL changes have been recently made in the staff at Westminster Hospital and School. Dr. Murrell has been appointed lecturer on Materia Medica and Therapeutics in place of Dr. Phillips, who has never sufficiently recovered from his railway accident to enable him to resume his duties at the hospital. Dr. Murrell's appointment creates a vacancy in the chair of Practical Physiology. Dr. Leslie Ogilvie has been appointed lecturer on Comparative Anatomy, *vice* Dr. Carter Blake, resigned, and Dr. George Ogilvie has been appointed lecturer on Experimental Physics in succession to the late Mr. Charles Brooke.

STATISTICS OF COLOUR-BLINDNESS.

The Report of the Committee appointed by the Ophthalmological Society to collect statistics of cases of colour-blindness presents many features of special interest. The secretary of the Committee, Dr. Brailey, with the assistance of sixteen colleagues, has examined 18,088 persons of all classes, of whom 1657 were females. It is at once curious and suggestive to find that while the average percentage of colour defects among men is 4·76, and 3·5 for very pronounced defects, it falls in women to the low figure of 0·4. This, if true, would seem to suggest a new sphere of labour for women. If women are comparatively free from colour-blindness, they are so far specially indicated for many of the less laborious occupations in which good colour-perception is desirable or absolutely indispensable. It is satisfactory to find that these last statistics confirm, in the main, those collected by the late Dr. George Wilson of Edinburgh nearly thirty years ago. This is especially noticeable as regards the comparative frequency of colour defects among members of the Society of Friends, particularly among the poorer section of them. Though the members of the Ophthalmological Society seem either not to have known the fact or to have forgotten it, Dr. Wilson found a considerable number of cases of colour-blindness among the members of the Society of Friends, and he was of opinion that this was not an accidental circumstance. He further believed that the largest proportion of cases of colour-blindness would on extended examination be found among the less accomplished male Friends in the larger cities. The other matters dealt with in the report prepared by Dr. Brailey will be found in another column.

THE CHAIR OF PATHOLOGY IN EDINBURGH.

The appointment, by a unanimous vote of the curators, of Dr. Wm. Smith Greenfield to the Chair of Pathology in the University of Edinburgh is a most creditable and auspicious event. We do not know whether it is more creditable to the University or to Dr. Greenfield. When an institution has reached that pitch of fame and prosperity now attained by the Edinburgh University it is apt to think that it may act partially and indifferently—that an important chair may be given away to a worthy graduate without respect to the abstract claims of candidates. It was well known that in this contest more than one graduate of the Edinburgh University was in the field who may reasonably hope ere long to find himself in the professoriate of this ancient and yet ever-young institution. But the curators seem to have regarded only the supreme question—Who is the fittest candidate for a Chair of Pathology? and to have acted accordingly. We congratulate them on the result.

SUPERANNUATION OF IRISH POOR-LAW MEDICAL OFFICERS.

On Monday last a deputation from the Irish Medical Association waited on the Chief Secretary for Ireland for the purpose of endeavouring to obtain a promise from the Government to introduce a Bill into Parliament for the compulsory superannuation of Poor-law medical officers in Ireland. The deputation was introduced by Mr. C. H. Meldon, M.P., and explained that they wished an Act to be introduced on the principles of the superannuation of civil servants. The interview was a lengthened one, and ultimately Mr. Forster promised to see the Vice-President of the Local Government Board on the subject, and give the points brought under his notice his best consideration. He, however, suggested that it would be advisable for some private member or members to introduce a Bill on the subject, and not leave the responsibility to the Government.

ALLEGED MANSLAUGHTER BY AN UNQUALIFIED PRACTITIONER.

An inquest in the case of Caroline Murrell has ended in the jury returning a verdict of "Manslaughter" against Mr. Scott, who is committed to the Old Bailey for trial. The deceased was on the point of her confinement, and at her request her husband fetched "a Mr. Scott from a dispensary at 547, Battersea-park-road." "Dr. Martin," of 1, Napier-terrace, also gave evidence to the effect that he allowed his name to be put on a brass plate outside of Mr. Scott's house. "He himself had not passed the necessary examination." Dr. Hills deposed that he was called in after death. He and Mr. Oakman made a post-mortem examination, and found that the deceased died from exhaustion, and might have been saved if proper measures had been taken. Mr. Scott honestly said he was a medical student, and, the patient being strong and healthy, he left Nature to complete her work. We must not prejudge a case which has to be tried formally. But we may at once say how unpleasantly cumulative is the evidence that London is covered with so-called "dispensaries," in any one of which poor people are led to think they are being treated by a qualified practitioner, and then find, or their survivors find, that they have been treated by a person totally unqualified.

THE EARTHQUAKE AT CHIOS.

The correspondent of the *Manchester Guardian*, who would appear to be a member of the medical profession, gives a graphic description of the harrowing scenes he witnessed at Chios after the appalling calamity which has desolated this fair isle. The following excerpt is of professional interest. The communication is dated April 8th :—

"We arrived here on Saturday last, after a quick run of thirty-six hours, and ever since I have been busily engaged setting fractures and binding up wounded heads and limbs. I am at work in a hospital made of ships' sails, and my patients arrive in an endless string of ghastly subjects. The sisters from the Deaconess Establishment of Smyrna are doing splendid work in the way of nursing, but it need not be mentioned that the workers are none too many. You cannot conceive the state of destruction and confusion on shore. The scene is indescribable. The houses of the town still standing are all deserted, the ground is still rocking slightly from time to time, and no one hardly ventures into the streets where there are walls still above ground. The search for victims amongst the ruins is, however, going on most actively. The distress everywhere is very great, but the committee now organised for the distribution of relief is sending off supplies of food to all parts of the island. Whilst death has overwhelmed whole families, there have been some remarkable escapes. I have had to-day under my hands a woman who was confined whilst under the ruins, and, strange to say, although three days elapsed before she was rescued, both she and the baby are still alive."

VIOLATION OF THE MEDICAL ACT.

At the Bristol Police Court a few days ago, Mayfield and Eugenie Lilly were charged with unlawfully, wilfully, and falsely pretending to be doctors of medicine and general practitioners in medicine. The defendants used to do their work in grand style. According to Police-sergeant Hunt they were accustomed to drive through the city in a carriage, with a Scotch piper. The male defendant claimed to have the right of practising under the 3rd of Henry VIII., providing that it should be lawful for any person having knowledge and experience of herbs, roots, and waters to practise, use, and administer them for any wound or outward sore. The magistrates were nevertheless quite convinced that he had violated the law, and inflicted the full penalty of £20. This decision still leaves the piper and the female defendant to carry on the business of specialists so long as they avoid the use of medical titles. This very proper prosecution was undertaken and carried through by the police of Bristol, who deserve much credit for tracking the defendant in his flight from town to town after learning that the magistrates of Bristol desired to see him.

HOSPITAL SATURDAY IN MANCHESTER.

The duty of the working classes in reference to Hospital Saturday is being warmly discussed in Manchester and other towns. A correspondent, "J. S.," of the *Manchester Guardian*, does not see the propriety of manufacturers bringing any pressure to bear on their men. In this we agree with him. We do not go with him in setting the Manchester and Salford provident scheme against the case and cause of the Manchester hospitals. No contributions to a provident dispensary scheme can possibly exonerate a thoughtful working man from some obligation to the large hospitals, which can be most easily discharged by a small periodical payment.

FELLOWSHIP OF THE EDINBURGH COLLEGE OF SURGEONS.

We have reason to know that the manufacture of Fellows of the Royal College of Surgeons of Edinburgh by the easy process of testimonials and payment, and on the nomination of, we must admit, some very respectable men, still goes on. We should like to be favoured with the periodical list of petitions for the Fellowship, and with the results of the ballot in individual cases. In a list before us there are petitioners from London, Edinburgh, Cumberland, Berwick-on-Tweed, Staffordshire, Stockport, Buxton, and Cape Colony.

According to a paragraph in *The Times* there were in the past winter in the twenty German Universities 21,164 students, of which 4405 were medical students. They were distributed as follows:— Berlin, 4107; Leipsic, 3326; Munich, 1890; Breslau, 1281; Halle, 1211; Tubingen, 1074; Gottingen, 959; Wurzburg, 921; Bonn, 887; Konigsberg, 788; Strasburg, 745; Marburg, 604; Greisfald, 599; Heidelberg, 543; Erlangen, 473; Freiburg, 443; Jena, 438; Giessen, 391; Kiel, 284; Bostock, 200.

Whilst at St. Petersburg recently the Duchess of Edinburgh visited the establishment for hospital attendants and assistant-surgeons instituted by the late Empress. She was accompanied by Dr. Berthenson, and conversed with many of the sick, remaining some time in the section of the building devoted to the patients suffering from typhoid fever.

At a meeting of the Reading Pathological Society held on the 13th inst., the following resolution was passed:—"That the members of this Society emphatically condemn any consultation between practitioners of general medicine and reputed homœopaths."

Dr. Planchon has been nominated to the Chair of Botany and Natural History in the Faculty of Medicine of Montpellier.

The death is announced of Dr. Ludwig Waldenburg, Professor in the University of Berlin, physician at the Charité Hospital, and editor of the *Klinische Wochenschrift*.

Madame Ivanitsky has been elected principal Clinical Physician of the University of Kharkov.

At the adjourned ordinary meeting of the Sanitary Institute of Great Britain, to be held at 9, Conduit-street, on Wednesday, April 27th, at 8 P.M., the discussion will be continued upon the address delivered at the last meeting—namely, "Suggestions for the Management of Cases of Small-pox and of other Infectious Diseases in the Metropolis and large Towns," by Dr. Richardson, F.R.S., Chairman of Council.

Not one of the essays on Diphtheria sent in by competitors for the prize offered by the Empress of Germany is, in the opinion of the appointed jury, worthy of the reward.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

River Tyne Port Sanitary Authority.—We regret to learn from this report that the medical officer of the Tyne ports, Dr. J. B. Bramwell, had been unable from illness to attend to his duties during the period to which it refers. The duties of the office were undertaken by the deputy medical officer, Dr. J. W. Bramwell, and upon him has devolved the drawing up of the report for 1880. From it we gather that the work of the port sanitary authority is now being as systematically carried on in the Tyne ports as at Sunderland, and doubtless with as good results; but the report wants the clearness and simplicity of arrangement which makes Dr. Yeld's reports so acceptable. The introduction of infectious diseases by shipping into the river is carefully watched, and the sanitary authority's floating hospital renders excellent service; while no less than 2997 vessels were inspected in the course of the year, an increase of 587 over those visited in 1879. Of these vessels, 1229 were reported in good sanitary condition; 1425 as "passable" only; and 343 in an insanitary state. With regard to these latter it was necessary for the port sanitary authority to take action, and they issued notices for certain matters to be done by the masters, 331 being complied with, the results of the notice not being ascertained in 12.

Faversham (Urban).—Mr. W. E. Atthill's report for this district for 1880 opens with the significant statement that in an extensive epidemic of measles which had prevailed early in the year, whooping cough being at the same time present in the district, he had been impressed by the facts that both diseases had "sprung up at the commencement almost entirely from those localities where the houses and their occupants are filthy and neglected, the former damp and wet, where large families crowd together in small ill-ventilated habitations, and where the provision of pure water is for the most part a questionable point." This sentence is painfully suggestive of sanitary negligence on the part of the sanitary authority. Nuisance removal appears, however, to be attended to, but strangely enough (and this particularly in an increasing town) house-drainage does not seem to have been seriously considered, and the sanitary authority are permitting to grow up in the new parts of Faversham evils similar to those which exist too largely in the old parts. Mr. Atthill is of opinion that the conditions which foster the spread of enteric fever foster also the spread of scarlet fever; he especially refers to the spread of the latter fever by means of contaminated drinking water, and it would appear that Faversham has, from the existence of shallow wells in the town, large opportunities for spreading maladies which may be conveyed by polluted water.

Halifax Union (Combined).—This combination consists of one *rural* sanitary authority (Halifax), and seventeen urban sanitary authorities, situated within the Halifax Union. Dr. Britton introduces his report for the several districts of which he is medical officer of health by some observations on the changes which have taken place in them since he was first appointed, now seven years and three-quarters ago. Speaking of the districts generally, he states that there has been a conspicuous abatement of nuisances, and that the nuisance inspectors do their work well, and maintain the greater general cleanliness of the district. The sanitary authorities themselves are more alive to the requirements needed for the proper sanitary administration of their districts. The offensive open ashpit and midden system, which in the beginning was in full operation throughout the district, is now much ameliorated by the substitution of better constructed ashpits and middens in some places, and by the covering up of hundreds in other places. The various water-supplies kept under constant supervision have been largely improved, the hospital accommodation for infectious diseases amended, and an immense quantity of detailed sanitary work done necessary to the improvement of the health-conditions of the districts. It seems almost an impracticable task to supervise the sanitary condition of the numerous districts under Dr. Britton's care. Nevertheless he contrives to do it to the full satisfaction of the authorities, to the very obvious and increasing benefit of the districts, and to present here an account of his doings in considerable detail for the combined district as a whole, as well as for the several districts entering into the combination. The report is a remarkable illustration of what may be done by a single individual working upon a thoroughly well-considered system.

St. Mary's, Newington (*Metropolis*).—Dr. W. Tiffin Iliff's annual report for 1880 for this district of the metropolis sets forth the annual work of a metropolitan health-officer when no special incidence of epidemic disease upon the locality under his supervision comes to disturb the even course of sanitary administration. He reserves general considerations on birth-rates and death-rates until the results of the recent Census can be obtained, feeling that estimates made of the population of his district at the present time must be misleading. Dr. Iliff, although convinced what sanitary work can do for the London poor is being done and slowly making progress, cannot avoid reflecting upon the gigantic task which is presented to health reformers. He admits the growth of pure and more open streets, the abolition of dire and ill-ventilated courts and by-ways; the destruction of "rookeries." "True," he says, "this is all good, but where are the hundreds and thousands to go? where are the healthy abodes and rents commensurate with their small earnings? How few really know the sad, sad story of the London poor, struggling, striving, and too often sinking, uncared for and unknown." But the causes producing this condition of things have been in operation for ages; the means of amelioration but a poor half-century, and yet we see progress.

Dorchester, Rural (*Eastern Division*).—Our attention has been directed to an error in our notice of Dr. Day's report for this district. The cesspool which we particularly referred to was unwittingly described as "*constructed*," when it should have been described as having been filled up and done away with.

Dawlish.—Estimated population, 1880, 3838; birth-rate 25·5 inhabitants; death-rate 22 9 (excluding the deaths of visitors 21·1).

A ROUND-ROBIN.

The Guardians of the Sedburgh Union, in Yorkshire, through the medium of their Chairman, have circulated a round-robin among other Boards of Guardians elsewhere, condemnatory of the proceedings of the Local Government Board, and trusting that Guardians in general will take part with them. This round-robin sets forth that the Sedburgh Guardians "whilst believing that the central authority should continue to be invested with the laying down and carrying out of general principles, subject to some elasticity according to different local circumstances, regret that the Local Government Board has gradually enforced to such an extent the absolute power with which they are invested that Boards of Guardians have now degenerated into mere machines, without authority or right to conduct their own affairs except on the hard and fast lines of the Central Department. On this subject my Board has recently addressed to the President of the Local Government Board a memorial, of which I enclose a copy, and I beg to request that you will bring it before your Board, with a view to their taking similar action."

THE SANITARY CONDITION OF NORTH WALES.

An important deputation, representing the sanitary authorities of four rural and five urban districts in the counties of Denbigh, Flint, and Merioneth, had an interview with the President of the Local Government Board a few days ago, with regard to the subject to which we referred the week before last—namely, the compulsory combination for the election of a single medical officer of health of the sanitary districts in question. The deputation protested against this course as against the feelings and the judgment of the ratepayers of the localities affected by it, and as not called for, in the opinion of the deputation, by the sanitary circumstances of the localities. It appeared, however, that the objections of the deputation dealt rather with the mode in which the Local Government Board had made its intentions known than with the intrinsic merits of the propositions. Mr. Dodson promised careful consideration of the objections brought before him, and hinted that he was not unwilling to delay action, if certain amendments were promised by the sanitary authorities in matters which he pointed out.

THE GRANTHAM HOSPITAL CASE.

We are exceedingly glad to have to state that the Supreme Court of Judicature have reversed the judgment of the Court below in the case of Eaton *v.* Basker so far as it concerns the Corporation of Grantham. Our readers will remember that Mr. Eaton claimed a sum of money from the Corporation or its sanitary committee for services rendered in a temporary hospital for scarlet fever during a severe epidemic in the town not long ago. Neither the services nor the justness of the charges were disputed, but the Corporation sought to escape responsibility on a legal point, which, although it was admitted by the judge in the lower court, Mr. Justice Stephen, was admitted in terms of stinging sarcasm. On appeal, however, the Supreme Court has now reversed Mr. Justice Stephen's judgment as concerns the Corporation of Grantham, and this most discreditable case as regards the local administration of Grantham will now end, we suppose, in the Corporation paying Mr. Eaton's rightful claim; we trust with the full costs to which he has been subjected also.

At a recent meeting of the Chelsea Vestry, the Sanitary Committee, among other matters, submitted with approval a series of suggestions made by the medical officer of health, Dr. Barclay, as to the manner in which the sanitary laws might be amended. The suggestions were as follows—namely, that penalties should be imposed by an Act of Parliament on people (other than duly qualified medical practitioners) who visited or attended any person suffering from any dangerous infectious disease, and who concealed the fact of such visit so as to endanger the health of other persons; secondly, on people who, after such visit, did not employ the best known means for the disinfection of clothing before coming in contact with other persons. A further penalty (suggested at £5) was proposed for neglect or delay of isolation. A motion that these should be sent to other vestries for their consideration was rejected, one of the members contending that such penal propositions would never be sanctioned by the Legislature, and that it was unlikely they would be tolerated by the British public. The propositions were withdrawn, and it was resolved to defer further action in regard to them until the receipt of the report of suggestions recommended by Kensington.

Among all the discussions which have gone on in the press about the infectious hospital dead-lock in the metropolis it has been reserved for our contemporary, the *Metropolitan*, to see that the true way out of the difficulty is to revert to the principles of administration in regard to hospitals found in the Sanitary Act, 1866. It justly condemns the cry for legislation, and, again fresh legislation and the difficulties raised about non-pauper patients, and roundly rates the Kensington people, and the Vestries and District Boards that have taken part with them, for their short-sightedness—a short-sightedness which tends to give them up, bound hand and foot, into the hands of the Local Government Board.

It is to be hoped that, as one of our contemporaries aptly expresses the matter, "the criminal craze of anti-vaccination" at Brighton will receive some check from the result of the recent election of guardians for that celebrated health-resort. Eight acknowledged anti-vaccinationists were brought forward as candidates for seats on the Board. Not only were all rejected, but an anti-vaccinationist who already had a seat on the Board, and was a candidate for re-election, was also rejected.

An instructive illustration of the extraordinary want of acquaintance not unfrequently found among the educated classes with the ordinary forms of local administration in this country, was recently furnished by a letter from a well-known gentleman printed in the columns of *The Times*. This gentleman in his anxiety to obtain better arrangements against fires ingenuously confounded the Local Government Board with Local Boards, and failed to distinguish questions which were for the Legislature from questions which local administration could deal with.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

Urban mortality showed a further increase last week. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 4639 births and 3343 deaths were registered last week. The births were no less than 547 below, whereas the deaths exceeded by 86, the average weekly numbers during 1880. The annual rate of mortality in the twenty towns, which had steadily increased from 20·6 to 22·4 per 1000 in the four preceding weeks, further rose to 22·9 last week. The lowest rates in the twenty towns last week were 14·8 in Brighton, 15·1 in Leicester, 18·1 in Norwich, and 19·4 in Hull. The rates in the other towns ranged upwards to 24·7 in Sheffield, 25·8 in Wolverhampton, 27·8 in Liverpool, and 28·3 in Portsmouth. During the thirteen weeks ending the 2nd inst. the death-rate in the twenty towns averaged 23·9 per 1000, against 25·7, the average rate in the corresponding periods of the five years 1876–80.

The deaths referred to the principal zymotic diseases in the twenty towns, which had been 315 and 339 in the two preceding weeks, further rose to 410 last week; these included 78 from small-pox, 81 from measles, 93 from whooping-cough, 65 from scarlet fever, and 47 from fever, principally enteric. The annual death-rate from these principal zymotic diseases averaged 2·8 per 1000 in the twenty towns, and ranged from 0·0 and 0·4 in Brighton and Leicester, to 3·4 in Liverpool and Newcastle-upon-Tyne, and 3·6 in London. Whooping-cough showed the largest proportional fatality in Manchester and Leeds, and scarlet fever in Wolverhampton. The 15 deaths referred to diphtheria in the twenty towns included 9 in London and 2 in Birmingham. The highest death-rates from fever, mainly enteric, were recorded in Plymouth, Liverpool, Sheffield, and Newcastle-upon-Tyne. Small-pox caused 85 more deaths in London and its suburban districts, and one in Oldham; no death from this disease occurred in any of the eighteen other provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 820, 899, and 921 at the end of each of the three preceding weeks, further rose to 940 on Saturday last, exceeding the number under treatment at these hospitals at any time since the spring of 1877. The number of new cases of small-pox admitted to these hospitals last week was 244, against 255 and 224 in the two preceding weeks. The Highgate Small-pox Hospital contained 85 patients on Saturday last, showing an increase of 8 upon the number in the previous week; 28 new cases were admitted during the week.

The deaths referred to diseases of the respiratory organs in London, which had slowly increased from 345 to 359 in the four preceding weeks, further rose to 395 last week; they were, however, 14 below the corrected average number in the corresponding week of the last ten years, and included 250 from bronchitis and 105 from pneumonia. The annual death-rate from lung diseases, exclusive of phthisis, was equal to 5·6 per 1000 in London last week. The rate from the same disease was no less than 7·6 in Liverpool, while it did not exceed 4·8 in Salford.

The causes of 75, or 2·2 per cent., of the deaths in the twenty towns last week were not certified either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths did not exceed 1·3 per cent. in London, while it averaged 3·1 per cent. in the nineteen provincial towns. No uncertified deaths were recorded last week in Portsmouth, Norwich, Bristol, or Nottingham; while the proportions of such deaths were largest in Oldham and Newcastle-upon-Tyne.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a half persons, the annual death-rate last week was equal to 22·1 per 1000, against 20·7 and 23·5 in the two preceding weeks; this rate was 0·8 below the average rate in the twenty English towns. The rates in the eight Scotch towns ranged from 19·0 and 19·9 in Greenock and Leith, to 29·2 and 29·7 in Perth and Paisley. The deaths referred to the principal zymotic diseases in the eight towns, which had been 69 and 82 in the two preceding weeks, declined again to 69 last week; they included 24 from whooping-cough, 12 from diarrhœa, 11 from diphtheria, 10 from scarlet fever, 7 from "fever," 5 from measles, and not one from small-pox. The annual death-rate from these zymotic diseases averaged 2·7 per 1000 in the eight towns, which was slightly below the average rate (2·8) from the same diseases in the twenty English towns. This zymotic death-rate in the eight Scotch towns ranged from 0·6 and 1·9 in Greenock and Perth, to 3·6 and 3·9 in Edinburgh and Dundee. The fatal cases of whooping-cough, which had been 16 and 26 in the two preceding weeks, were 24 last week, of which 10 occurred in Glasgow, 5 in Edinburgh, 5 in Dundee, and 2 in Aberdeen. The 12 deaths from diarrhœa showed a decline of 8 from those returned in the previous week, and included 6 in Glasgow and 3 in Dundee. The 11 deaths referred to diphtheria were within one of the number recorded in each of the two previous weeks; 4 occurred in Glasgow, 3 in Edinburgh, and 2 in Dundee. The 10 fatal cases of scarlet fever exceeded the numbers in recent weeks, and included 6 in Edinburgh and 2 in Glasgow. The 7 deaths referred to "fever" (typhus, enteric or typhoid, and simple continued) were fewer by 4 than the number in the previous week, and included 3 in Glasgow; the annual death-rate from this cause scarcely differed from that which prevailed in the twenty English towns during the week. Four of the five deaths from measles occurred in Glasgow. The deaths referred to acute diseases of the lungs in the eight towns, which had been 138, 146, and 163 in the three preceding weeks, declined again to 144 last week, and were equal to an annual rate of 5·7 per 1000, against 5·1 from the same diseases in London. The greatest proportional fatality from lung diseases occurred last week in Glasgow, Perth, and Greenock.

HEALTH OF DUBLIN.

The rate of mortality in Dublin although still excessive showed a further decline last week. The annual death-rate in the city, which had been equal to 30·8 in each of the two preceding weeks, declined to 29·0 last week. During the thirteen weeks ending on the 2nd instant, the death-rate in the city averaged no less than 37·8, against 23·4 in London and 22·3 in Edinburgh. The 185 deaths in Dublin last week showed a decline of 12 from the number in the previous week, and included 12, or scarcely more than 6 per cent., which were referred to the principal zymotic diseases, against 19, 15, and 14 respectively in the three preceding weeks. These 12 deaths from zymotic diseases included 7 from fever (typhus, enteric or typhoid, and simple continued), 2 from scarlet fever, 2 from diarrhœa, 1 from whooping-cough, and not one either from small-pox, measles, or diphtheria. The annual death-rate from these zymotic diseases did not exceed 1·9 per 1000 in Dublin last week; whereas it was 3·6 both in London and Edinburgh. The deaths referred to fever, which had been 12, 7, and 8 in the three preceding weeks, were 7 last week; the annual death-rate from this cause was nearly four times as high in Dublin as the average rate in the twenty English towns. The deaths referred to the other principal zymotic diseases were again exceptionally few. The deaths of infants showed a decline, and those of elderly persons were fewer than in any recent week.

THE HEALTH OF CAPE TOWN.

We are in the receipt of a Government notice, issued by the Colonial Secretary of the Cape of Good Hope, which contains a return of vital statistics prepared by the Colonial Medical Committee, from information furnished by the Town Council of Cape Town, for the year 1880. We fear, however, that the statistics are scarcely of a character to afford much trustworthy information bearing upon the health condition of Cape Town. In the first place, the population is roughly stated to be 50,000, without any clue to the manner in which this estimate is arrived at; whereas a leader in the *Cape Times* declares 35,000 to be a reasonable estimate of the total population of the municipality of Cape Town. We shall presently see what an important bearing these wide variations in the estimates of the population have upon the vital statistics of the town. It is evident that registration of births, whatever may be the case as regards registration of deaths, is comparatively inoperative in Cape Town. A note to the first table in the report states that "the number of children registered at the Town House, as born during 1880, amounts to only 326 in a population of 50,000." This represents a birth-rate of but 6·5 per 1000 of the population; and as the death-rate is stated to be 21·8, the report adds the words, "At this rate the population must soon die out from want of recuperative power." It is quite evident that birth registration is a farce in Cape Town, and that the numbers recorded afford no clue to the number of births occurring among the population, and it seems somewhat surprising that this fictitious birth-rate should be referred to in the official return as evidence of want of recuperative power in the population. When we begin to analyse the mortality statistics they do not appear to be much more trustworthy than the statistics of births. The number of deaths registered at the Town House in 1880 is reported to be 1189; by exclusion of stillbirths, the number is reduced to 1092, which gives (calculated upon the estimate of 50,000) a death-rate of 21·8 per 1000. If, however, the *Cape Times* is justified in assuming that 35,000 is a more reasonable estimate of the population, it follows that the death-rate in Cape Town during 1880 was equal to 31·2 per 1000, instead of 21·8. Such a death-rate as 31·2 would afford the strongest evidence of insanitary condition. The return includes certain figures bearing upon the ages of the decedents and the causes of the deaths. The age statistics are materially depreciated by the fact that age is not stated in 13 per cent. of the deaths recorded. With regard to the deaths of children, 411 deaths are reported under five years of age; but it is impossible to estimate how many of the 136 cases in which the age was not stated were of children under five years of age. It is probable, however, that not far short of half the total deaths were of children under this age, and it appears that the 411 deaths under five years included 252 from such ill defined causes as convulsions, teething, and debility, in addition to 29 in which the cause was unknown. The causes of death are evidently most vaguely returned, very considerable numbers being returned under the headings inflammation, dropsy, consumption, &c. With regard to the so called zymotic diseases, whooping-cough is debited with 36 deaths, whereas only 2 deaths were referred to measles, 5 to diphtheria, including ulcerated throat, and not one to small-pox or scarlet fever. No less than 41 deaths, however, were referred to fever, including enteric and undefined fever, which affords conclusive evidence of dangerous filth contamination in some form or other. Perhaps the most satisfactory feature of the return of causes of death is the remarkably small proportion of deaths from acute diseases of the lungs, among which but three were referred to bronchitis. Before another annual return for Cape Town is issued a Census will have set at rest the serious discrepancies between the local estimates of population; and it may be further hoped that the value of the return as a contribution to sanitary statistics will be further increased in other ways.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

DR. B. W. RICHARDSON, F.R.S., ON THE MANAGEMENT OF SMALL-POX ETC. IN THE METROPOLIS AND LARGE TOWNS.

On the 13th instant Dr. B. W. Richardson delivered an address before the Sanitary Institute on the Management of Cases of Small-pox and other infectious Diseases in the Metropolis and Large Towns. This, the first intervention, we believe, of Dr. Richardson in the question which at the present moment is agitating sanitary workers in the metropolis, brought together a large audience of persons having more or less responsible relations with metropolitan sanitary administration, and anxious to hear what new light the learned Chairman of the Council of the Sanitary Institute might throw upon the difficulties of the situation. The address first touched upon the obstacles that lie in the way of the practical management of persons suffering from infectious diseases in large cities and towns. It then treated briefly of the registration of diseases, and next entered upon matters of more immediate interest to the public at the present moment. Dr. Richardson declared himself utterly opposed to the collection together of great numbers of infectious cases in large hospitals, and to the management of such cases and of the institutions prepared for them by an organisation common to the whole of the metropolis. The results of recent experience in this matter confirmed an opinion formed on other grounds, and which he would now reiterate, that every parish should bear its own burden, and accept its own responsibilities for the retention and management of the infectious cases occurring within its own boundaries. He would have parish hospitals, each of which should be constructed to receive twenty-four patients (preferably twenty), and each constructed after a particular fashion. As many of these hospitals as may be found to be necessary should be constructed in each parish, and they should be placed under the supervision of the medical officer of health, and under the entire control of the sanitary authority, becoming an essential element in the sanitary administration of the parish. Difficulty of acquirement of sites he would meet by placing these small hospitals upon the upper part of terraces of houses, to be acquired by the parish authorities for the moment. The hospital should be constructed on the cellular system, built of iron (so that its walls could be purified both by fire and water), lighted and ventilated from the roof, and so arranged and managed that its presence above would not militate against the letting of the houses below. A more startling or bolder scheme was, perhaps, never before urged even by Dr. Richardson himself, and its novelty for the moment seemed to put out of sight the not less bold proposition to revert to parochial administration in the present difficulty as to the provision of hospital accommodation for the infectious sick. The discussion on the address was not completed during the evening, and it has been adjourned until the 27th inst. We reserve further observations on Dr. Richardson's suggestions until after the termination of the discussion.

THE DEATH-RATE OF DUBLIN.

A conjoint report of the King and Queen's College of Physicians and of the Royal College of Surgeons in Ireland on the death-rate of Dublin has been issued. The report begins with the admission that "the existence of an excessive mortality in the City of Dublin is proved beyond doubt;" and proceeds to set forth the causes to which this should be assigned, and the measures, both present and future, which in the opinion of the Colleges are requisite to combat the high mortality. First, it expresses the opinion that this high mortality is not to be attributed to the system of death registration peculiar to the city, a notable increase of population, the immigration of sick persons from the provinces, the geological conditions of Dublin, or the climatology of the city. The report next recognises the following conditions as the most potent in determining its excessive mortality—viz.: (*a*) The faulty structural condition, insanitary arrangements, and overcrowding of tenement houses ("the prime source and cause of the excessively high death-rate of Dublin"). (*b*) The insufficiency of public and domestic scavenging. (*c*) The presence and the unsatisfactory condition of numerous slaughter-houses, cow-yards, and manure depôts within the most crowded parts of the city. (*d*) The defective state of the drainage of many houses, even in the best parts of the city. (*e*) The defective construction of new dwelling-houses. (*f*) The use of cellars as human habitations or as receptacles for decaying animal and vegetable refuse. (*g*) The dissemination of noisome and poisonous vapours by chemical and other manufactories. (*h*) The very uncleanly and intemperate habits of certain classes of the people. (*i*) The saturation of the subsoil. (*j*) The spread of infection by—1, the concealment of infective disease; 2, the inadequate disinfection of rooms and clothing; 3, the injurious practice of wakes. (*k*) The insufficient provision for the conveyance of infected persons to hospitals. Each of these subjects is considered briefly, together with the remedial measures to which they should give rise, and finally the opinion is deliberately expressed that:—"The City of Dublin is, and has been, unhealthy in an excessive degree, and its extraordinary death-rate is attributable—not to errors of computation, or irremediable circumstances—but to long-continued disregard of sanitation, and the omission to enforce the legal means provided for a remedy." The report is signed for the King and Queen's College of Physicians by Dr. J. Magee Finney, and for the Royal College of Surgeons, Ireland, by Dr. Stannus Hughes, F.R.C.S., and it forms a most important contribution to the sanitary polemics of Dublin.

DIARRHŒA.

A combined meeting of the North-Western, Northern Counties, and Yorkshire Associations of Medical Officers of Health was held at the Guildhall, in York, on the 7th inst., Mr. S. W. North, medical officer of health for York, in the chair. The subject selected for consideration was diarrhœa, considered with reference to its causes, the prevalence of infantile diarrhœa during the third quarter of the year, and the pathology of uncomplicated diarrhœa. The meeting derived a special interest from the presence at it of Dr. Ballard and Dr. Parsons of the Medical Department of the Local Government Board; the former gentleman, as is known, being engaged in an official inquiry on the subject for discussion by the meeting. After some brief remarks by the Chairman opening the proceedings of the meeting, papers were read by Dr. J. C. Reid "On Some of the Causes of Infantile Diarrhœa;" the Chairman on the "History of 100 Cases of Diarrhœa;" Dr. M'Cook Weir, entitled, "Is Diarrhœa a Zymotic Disease?" and by Mr. R. S. Low, "Infantile Diarrhœa from a rural point of view." After the reading of the papers an active discussion took place, in which part was taken by the Chairman, Dr. Britton (Halifax), Dr. Scott (Ilkley), Dr. Butterfield (Bradford), Dr. Eastwood (Darlington), Dr. Blacket (Durham), Dr. Wilson (Doncaster), Dr. Parsons, and Dr. Ballard. Dr. Ballard gave some account of the inquiry respecting diarrhœa upon which he was entering for the Government, and explained that his presence there was partly in the hope of enlisting the aid of the members present in his work. "He was seeking to form a brigade of earnest workers, and he should regard it as a favour to have the assistance of any medical man who would work on the lines laid down." Dr. Ballard's observations were very warmly received, and we gather from his remarks that his inquiry begins with a very fair promise of success.

COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES.

The following resolutions in reference to this subject have been adopted by the Executive Committee of the Dublin Sanitary Association:—"That, in the opinion of this committee, any Bill to provide for the notification of infectious diseases in Ireland should be compulsory, and should apply to every sanitary district in Ireland." "That the medical practitioner (if any) in attendance shall either note directly to the sanitary authority the existence of a case of infectious disease, or else hand a notification to the occupier of the house, or person in charge of inmate." "That a fee shall be payable only in case of the medical practitioner reporting directly to the sanitary authority." "That where no medical practitioner is in regular attendance on a person suspected to be suffering from an infectious disease within the meaning of this Act, it shall be incumbent on the occupier, &c., to obtain a certificate from a registered medical practitioner as to the nature of the disease, and in cases where the sick person is entitled to gratuitous medical attendance, said occupier shall obtain such a certificate from the medical officer of health of the district in which the sick person resides."

THE PUBLIC HEALTH (SCOTLAND) ACT.

The Magistrates and Council of Glasgow, as Local Authority under the Public Health (Scotland) Act, 1867, have approached the authorities of other cities and large towns in Scotland with the view of directing their attention to, and, if so arranged, conferring with them regarding the existing state of sanitary regulation. The magistrates and council desire also to arrange for joint and co-operative effort on the part of these authorities in the direction of approaching and inducing the Government to amend the Public Health Act for Scotland, and to embody in the amended Act such provisions as may be mutually deemed desirable and necessary. With this view they have transmitted to the authorities in question a statement regarding (1) the position of sanitary legislation for Scotland; (2) outlines of suggested amendments of existing sanitary laws; and (3) suggestions regarding the constitution and powers of the central and local authorities empowered to administer the sanitary laws of Scotland. The Local Authority submit certain suggestions in the way of amending existing provisions of the law.

VACCINATION AND REVACCINATION.

Dr. F. Chance has communicated to *The Times* a striking example of the value of revaccination as protective against small-pox. The master of a ship sailing from London for New York had before sailing taken on board the vessel a son suffering from small-pox. The surgeon, unwilling to denounce the master and have the case removed from the vessel, sought to obviate the evil effects its presence in the ship might have upon the crew by revaccinating them. Unfortunately the supply of vaccine lymph he was able to procure was insufficient for the revaccination of the whole of the men, and, as the event proved, while the revaccinated escaped the contagion of the disease, the men who had not been revaccinated suffered from it, the greater number contracting the malady, and three died.

Dr. Robert Cory, in a letter to *The Times*, has pointed out that the efficacy of vaccination does not rest upon statistical data alone—data of which it is not at all times easy to understand the whole meaning, or to avoid fallacies in dealing with them—but on the result of actual experiment. The efficacy of vaccination was in the first instance proved by very numerous but unsuccessful attempts to inoculate the vaccinated with small-pox, so numerous as to justify the Legislature to forbid the practice of inoculation by small-pox in any case, and to first facilitate and then enforce the practice of vaccination. It is to be regretted that Dr. Cory did not state his position at greater length. For the large use of complicated statistical data to show the efficacy of vaccination has to a great extent confused a very simple question, and tends still more to confuse it.

It is very gratifying to find architects beginning to take an active interest in the sanitary aspects of architecture. This interest was excellently shown by a lecture lately delivered before the Architectural Association by Mr. Ernest Turner, and which is now published from the columns of the *Builder* in a separate form. Professor Kerr observed, in the discussion which followed the reading of the paper, and which is stitched up with it, that he was very glad that the important subject dealt with "had at last reached the stage of being seriously discussed by architects." We are glad also, and feel assured that serious discussion of the subject by them will possibly not only remove one of the formidable obstacles in building healthy houses, but will also enlist heartily in practical sanitary work the only men we can confidently look to for the construction of wholesome dwellings and for the due development of the structural conditions on which this wholesomeness must depend.

A correspondent of *The Times*, writing under the initials "F.R.C.S.," sends a long letter on the unwholesomeness of houses, in which he instances the important principle as to houses in general, and particularly London houses, that they should be so furnished within as to afford the fewest opportunities for the collection of dust and dirt. He would have, in fact, the interior of the dwelling-house fitted up on the same principles as the interior of a hospital ward in regard "to dust-traps," and he thinks that he has succeeded in doing this in his own house, while at the same time giving sufficient regard to the æsthetics of the interior. The letter is deserving of attentive study.

LEDWICH SCHOOL OF MEDICINE, DUBLIN.—The following prizes have been awarded at the termination of the winter session:—Junior Anatomy: J. H. Griffin, 1st; J. Neill, 2nd. Senior Anatomy: A. E. W. Ramsbottom and J. Niblock, equal. Surgery: P. Walsh, 1st; W. R. P. Jones, 2nd. Practice of Medicine: C. Kenny, 1st; W. R. P. Jones, 2nd. Physiology: T. Cashel, 1st; J. F. Russell, 2nd. Chemistry: J. Clancy, 1st; J. F. Russell, 2nd. Midwifery: D. W. Whitfield, 1st; A. G. Beacom, 2nd.

THE new infirmary in course of erection on th Castle House Estate at Homerton for the Hackney Union and designed for the accommodation of 150 pauper patients is to be opened on May 24th next.

THE SERVICES.

ADMIRALTY.—Deputy Inspector-General of Hospitals and Fleets John Bernard to be Inspector-General of Hospitals and Fleets in Her Majesty's Fleet, with seniority of the 1st instant. Fleet-Surgeon Timotheus John Haran to be Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet, with seniority of the 1st instant.

The following appointments have been made: Dep. Inspect.-General J. T. U. Bremner, M.D., to the Chatham Division of Royal Marines, vice Bernard; Deputy Inspector-General G. Mason, M.D., to Bermuda Hospital, vice Bremner; Fleet-Surgeon F. A. Brice to the *Britannia*, additional, for cadets' sick quarters; Fleet-Surgeon G. Jackson to the *President*, additional, for recruiting quarters; Fleet-Surgeon A. B. Messer, M.D., to the *Northampton*, vice Haran; Fleet-Surgeon W. Edney to Plymouth Hospital, vice Messer; Staff-Surgeon R. Hay to the *Duncan*, vice Brice; Fleet-Surgeon Henry Hadlow to the *President*, additional; Fleet-Surgeon James C. Eastcott to the *Revenge*, vice Hamilton, retired; Staff-Surgeon Mark A. Harte to the *Impregnable*, vice Hadlow; Staff-Surgeon Matthew Trevan to the *Britannia*, vice Telfer, retired; Surgeon Joseph Crowley, M.D., to the *Impregnable*, additional, for service in the *Nautilus;* Surgeon William J. Christie, M.B., to the *Impregnable*, additional, for service in the *Pilot;* Surgeon John J. Dinnis, M.D., to the *Implacable*, additional, for service in the *Liberty;* and Surgeon George F. Wales to the *Ganges*, additional, for service in the *Sealark;* Surgeon G. W. Low to the *London*, vice Boland; and Surgeon C. E. Godding to the Chatham Division of Royal Marines, vice Drew.

[In the list of retirements from the service published in THE LANCET of March 19th, page 478, Surgeon-Major James Atkinson West Spence is erroneously described as "surgeon."]

SUPREME COURT OF JUDICATURE.

COURT OF APPEAL—APRIL 12TH.

(*Sittings at Westminster, before* LORDS JUSTICES BRAMWELL, BAGGALLAY, *and* LUSH.)

EATON *v.* BASKER.

THIS was an action by a medical man to recover fees for attendance upon a contract made in the following circumstances:—In June, 1878, an outbreak of scarlet fever occurred in Grantham and the neighbourhood, and a committee was appointed under section 200 of the Public Health Act, 1875, by three urban sanitary authorities, to exercise the powers conferred by section 131 of the Act, enabling the authorities to provide hospitals or temporary places for the reception of the sick. The committee erected tents for the reception of the sick, and directed Mr. Ashby, the medical officer of the sanitary authorities, to apply to the plaintiff to attend the patients. The plaintiff agreed to do so at the rate of 5*s.* 3*d.* a day per tent, and his charge eventually amounted to £97 7*s.* 9*d.* The amount not being paid, the plaintiff brought this action to recover it from the members of the committee and the Corporation of Grantham, in whom the powers of the three urban sanitary authorities had become vested. At the trial, before Mr. Justice Stephen, the jury were discharged, and the learned Judge held that the committee were not liable collectively, because they were forbidden to contract by section 200 of the Public Health Act, 1875, and were not liable individually because the contract was not with the members of the committee personally; and that since eventually more than £50 became due it was a "contract whereof the value or amount exceeded £50" within section 174 of the Act, and ought to have been under seal; and that, not being under seal, no action lay on it against the urban authority, though they had had all the benefit of it. Judgment having been entered for the defendants, the plaintiff appealed.

Mr. Finlay argued for the plaintiff; Mr. Lawrance, Q.C., and Mr. Dugdale for the defendants.

Their Lordships were of opinion that the contract entered into between the parties was not at the time of making it known to exceed the amount or value of £50, and therefore did not come within section 174 of the Public Health Act, 1875. The judgment of Mr. Justice Stephen would therefore be reversed as against the corporation, but as regards the committee there could be no case against them, and the judgment in their favour would be sustained.

Correspondence.

"Audi alteram partem."

THE MEDICAL CONSULTATIONS IN THE CASE OF LORD BEACONSFIELD.

To the Editor of THE LANCET.

SIR,—I have to request you will do me the favour to republish in your columns the accompanying letter. I could have wished to have made some further remarks upon it, but I must forbear; silence becomes the chamber of death. When, in the course of time, the painful feelings of to-day have passed, something may remain to be said.

In the meantime, I am, Sir, your obedient servant,

WILLIAM W. GULL.

Brook-street, Grosvenor-square, W., April 19th, 1881.

"*To the Editor of the* '*Standard.*'

"SIR,—As, in the *Standard* of to-day, you express, as from a public point of view, some censure on Sir William Jenner for not complying with Dr. Kidd's request to meet him in consultation, will you afford me space to say that I desire to bear my part in that censure, whatever it may be?

"Sir William Jenner, as a friend and colleague, conferred with me before answering Dr. Kidd's note, and I entirely concurred with him in his reply, which was to the effect that, though ready to give his services in so anxious and important a case, he could not, consistently with his duty to the patient, co-operate with one who, according to his own statement, has a double set of convictions in the treatment of disease. For, whatever other objections might be raised as to etiquette and the like, it is certain that the welfare of a patient is endangered when there is a tendency to compromise. I am, Sir, your obedient servant,

"74, Brook-street, April 15th." WILLIAM W. GULL.

*** We gladly reproduce the letter addressed to our lay contemporary. It is a timely expression of opinion on the course taken by Sir William Jenner, which the medical profession cannot fail to appreciate. Sir William Jenner's action has been in the strictest accord with the views of the great body of his brethren; and it is pleasant to know that Sir William Gull is in sympathy with his colleague in respect to a line of conduct which has commended itself to the judgment of the profession, and which public opinion will hereafter not less warmly approve. For the moment our comments on the subject, in connexion with this particular case, are necessarily suspended; but later on, the matter must be reverted to on the highest public grounds.—ED. L.

THE MENTAL ELEMENT IN THE ETIOLOGY OF GOUT.

To the Editor of THE LANCET.

SIR,—Attention has recently been directed in your columns, and elsewhere, to the mental phase of treatment in cases of gout. Will you allow me to submit for the consideration—or, perhaps, I ought to say the recollection—of the profession the fact that mental conditions and forces play a conspicuous part in the causation of that disease. I cannot ask the necessary space to adduce demonstrative evidence, or even arguments, in support of this proposition, so I will content myself with a series of dogmatic assertions on the subject. If they are not held to be convincing, they may, at least, prove suggestive.

The morbid state in gout is characterised, if not caused, by the accumulation of uric acid in the blood. It disappears from the urine and is found in the blood; and *pari passu* the normal conversion of uric acid into urea is either arrested or diminished.

It is not necessary to show that the injection of uric acid into the veins of an animal will produce gout, just as it is not necessary to prove that diabetes can be induced by the introduction of sugar into the circulation. There is a special centre in the floor of the fourth ventricle which either excites to the formation of sugar or promotes its destruction—we do not know which, though Dr. Pavy has, as it seems to me, thrown new and true light on this subject in his singularly lucid lectures (THE LANCET, March 30th, 1878); and there is probably also a centre which determines the formation or the destruction of uric acid. These centres may be abnormally active or inactive in the respective maladies, so that they either produce too much of the several materials or do not destroy them with due speed. In any case, *it is the morbid state of the centres which constitutes the disease.*

The persons who suffer most severely from gout are those who either inherit or have acquired a considerable faculty for exertion—or, in other words, great potential energy—and the period at which they begin to suffer from the affection is usually that at which they cease to consume or pass off this energy by transforming it into kinetic force in work. Cases in which gout troubles its victim early in life are nearly always instances of a particularly strong inheritance, or of a complete change in the outlet of force. For example, a youth may inherit gout from his maternal or paternal grandfather, or great-grandfather—generally through the maternal line—and suffer early in life, because he is unable to take as much exercise as will consume or work off all the uric acid he generates; or he may be incapacitated for this chemico-physiological function by having adopted a habit of life which is at too great variance from the habit of his ancestors. Thus, perhaps, they have worked with their muscles, and he works with his brain. It is, however, commonly in adult life that the gouty diathesis begins to develop itself, and the appearance of marked symptoms is generally synchronous with the cessation of accustomed forms of individual work, whether intellectual or muscular. The man-of-muscle abandons his robust life, and the man-of-mind desists from or diminishes his cerebral exercise.

There is a perpetual effort in the gouty constitution to get rid of the uric acid. When it cannot be readily transformed into urea and passed away in the urine, or worked off by the combustive processes of a local inflammation—in some part where the venous circulation is slow, or the currents are embarrassed and the flow of blood towards the heart is retarded, as explained in Mr. Gay's admirable paper on the "Anatomy of Gout," THE LANCET, May 19th, 1877,—there is a perpetual tendency to lung-disturbance, and probably not only gouty bronchitis or catarrh, as shown by Sir Henry Holland in his Medical Notes, but gouty congestion of the lung, and a specific form of pneumonia is a very common consequence. It is precisely what we should expect that blood charged with uric acid would, in default of other ways of relief, set up irritation in the organ through which its organic elements receive their oxygen and get rid of their carbonic acid. These pulmonary affections of the gouty subject occur chiefly in cases in which the diathesis is either subject to the repressive influence of atavism, or the vitality of the body, as a whole, is of low type or depressed by circumstances.

As a rule, the most active organ at the period of life and under the conditions described, when the gouty symptoms occur, is that upon which the stress of the malady falls. Many cases of pain, disturbance, and disease are due to blood charged with uric acid circulating languidly, or, which amounts to the same thing, in relatively large quantities through the vessels of the cerebrum. Special paralyses and convulsions are caused by the uric acid poison—if I may call it so—acting on the nerve-centres. Numberless cases of hæmorrhoidal affection, and prolapse of the rectum, are occasioned by the irritation arising from this cause—namely, the accumulation of uric acid in the blood; and it may even produce a local urethritis resembling gonorrhœa, while prostatic inflammation and disease are in, perhaps, a large proportion of instances due to the same mischievous agency. In short, there is scarcely a malady of mind or body which may not have its origin in gout. The colchicum-test, as it used to be called, will often lead to the recognition of latent gout as a source of disease or discomfort ranging from diarrhœa to diplopia, from sleeplessness to eczema.

The reader will ask what has all this to do with mental causes or influences? Simply this, that in every case it is the equilibration of energy and force, of power and action, which is at fault. Either there is a relative excess of potential energy or a deficiency of kinetic force. Under normal conditions muscular action is followed by an increase of urea in the urine. This is commonly, and doubtless rightly, held to be the result of the decomposition of effete muscular tissue; but the *will*, or mental purpose, to perform muscular exercise *without* action may set up a nervous process which leads to the formation of uric acid in the blood, just as the thought of food will stimulate the salivary, and probably also the gastric and intestinal, glands to pour out their proper secretions. The whole body, with every constituent system, is energised by the same force that sets the brain in action, and produces thought; and every chemico-vital process, not excepting that of the formation of uric acid, is originated by the mind acting consciously or unconsciously, voluntarily or automatically. When the mind acts, so to say, without the body, the impulses are unsatisfied—as in nightmare—and there is no outlet for the products of this action, so that they have a tendency to accumulate in the blood. Myosin accumulates in the muscular tissue, and produces catalepsy, when, in the so-called "hysterical" state, the morbid mental condition inhibits action without arresting the impulse to act.

If I am right, the treatment of gout under all its forms and varieties of actual or abortive development should be in the first place and in the main *mental.* The gouty constitution requires to be treated for the reduction or diversion of its occult mental and nervous energies, not less than for the relief of their expressed physical indications. In short, suppressed or undeveloped gout is like the subterranean operation of volcanic forces, the attack being the earthquake or eruption, with an outpouring of lava. If we are to deal with the *cause* of the disease we must equilibrate the mental energy with the overtly organic or animal forces at work in the system. It is seldom enough to reduce the nitrogenous elements of the food, or to enjoin such exercise as may seem likely to lead to the consumption of the supplies assimilated. It is necessary to command those mental impulses which set up the processes that make life a round of continuous activities mutually destructive unless correlated and controlled. The inheritor or self-producer of mental and nervous energy which ought to find its natural expression in action, either cerebral or muscular, will be gouty if that expression is prevented while the mental motor impulse is not itself inhibited. Gout is the nightmare of an organism constitutionally bent on action, and automatically performing the collateral and contingent chemico-vital processes normally attendant on action, while the action itself is omitted or restrained. The remedy must be sought in grappling with the motive energy, rather than in striving to obviate the train of morbid consequences to which its repression gives rise. Or if this be impossible, as will often happen, a way of working off the products of volition or subconscious energy must be found. I am, Sir, yours, &c.,

Welbeck-street, W. J. MORTIMER GRANVILLE.

CASES OF SUDDEN OBSTRUCTION OF THE ŒSOPHAGUS.

To the Editor of THE LANCET.

SIR,—The case related by Mr. Thornton of cancer of the œsophagus, of which the first symptom was a *sudden* obstruction to the passage of food, is so important in relation to diagnosis that it may be well to draw attention to the accounts of two similar cases in order to show that, although the occurrence is very uncommon, it must nevertheless be accepted as one of the irregular modes of onset of the symptoms of this disease.

The first case is recorded in the Pathological Transactions for 1859 (vol. x., p. 165), by Dr. Baly. The patient, a gentleman fifty-six years old, while at dinner felt that the solid food he had swallowed lodged opposite the lower part of the chest, and he was obliged to leave the table and reject it. At the end of a week the same thing happened again, and was relieved in the same fashion. From that time it frequently occurred, and five or six months later the patient died from a tolerably extensive epithelioma two inches above the cardiac orifice of the œsophagus.

The second case is related by Dr. Traube in the *Archiv der Heilkunde* (Bd. xvi., S. 282). The patient, also a man of fifty-six, felt a piece of hard beef stick in the œsophagus one day during the month of October, 1873. From this time he experienced great difficulty in swallowing, and in May, 1874, died from widespread epithelial ulceration of the middle portion of the œsophagus.

In neither of these cases was the obstruction so complete after the sudden onset as in Mr. Thornton's case. Possibly the nervousness of Major —— rendered his symptoms more severe. I would suggest, as the most probable solution of the first case, that of temporary obstruction of the œsophagus in a lady, that the piece of meat which lodged in the œsophagus was still there when the bougies were passed, and was the immediate cause of the obstruction of the right side of the tube. I remain, Sir, yours obediently,

HENRY T. BUTLIN.

Queen Anne-street, W., April 16th, 1881.

THE CHLOROTIC MURMUR.

To the Editor of THE LANCET.

SIR,—I did endeavour "to use the utmost care not to misinterpret" Dr. Balfour's views. My statement, for it was not a criticism, to which he has taken exception, referred solely to the basic cardiac murmurs of chlorosis, as the context distinctly shows. I had taken it for granted that a murmur heard over the præcordia was *endocardial*, and in discussing the points for and against its being organic or functional, I say "the so-called functional murmurs are always systolic, and are either aortic pulmonary or mitral;" adding in a foot-note, "Naunyn, George Balfour, and others deny that the inorganic murmurs of chlorosis are ever arterial, and say that they are due to mitral regurgitation," *meaning by the term arterial aortic and pulmonary basic murmurs.* After again carefully reading Dr. Balfour's Chapter vi., and referring to the paragraphs quoted in my letter of Feb. 19th, I still think that my conclusion was *logically* correct. I also fail to see that Dr. Balfour anywhere indicates that "the *ultimate result* logically and pathologically must be a systolic aortic murmur."

I differ from Dr. Balfour in thinking the opinions of Hayden and Fothergill beside the mark; on the contrary, they seem to me forcible arguments against his explanation of the reduplicated second sound. I am aware that Ceradini states that the "systolic closure of the valves," as he terms it, is attended by the production of sound; but I understand that this point is difficult to prove and is not accepted as established by physiologists. If this systolic closure is noiseless, Dr. Balfour's explanation cannot hold. But granting, for the moment, that the "systolic closure" is attended by sound, I am still disposed to doubt the correctness of Dr. Balfour's view—viz., that the separation between the systolic and diastolic closure of the segments of the pulmonary valve, caused by the increase of the arterial blood pressure within the pulmonary circuit, is the only rational explanation of a reduplicated sound.

In the normal condition of the blood tension the diastolic closure of the valve, which results from the elastic recoil of the vessel, follows so immediately after the systolic closure that the resulting sound (the normal second sound) is single. Is there any reason for supposing that where the blood tension is increased the "diastolic closure"—i.e., the recoil of the vessel—will be postponed? Should we not rather expect that, if anything, it would be anticipated?

With all respect, then, to Dr. Balfour's great authority, I am disposed to think that the view which I adopted in my lecture is a more probable explanation than the one which he has advanced.—I am, Sir, your obedient servant,

Edinburgh, April 16th, 1881. BYROM BRAMWELL.

⁂ This discussion must now close.—ED. L.

PROVIDENT DISPENSARIES IN MANCHESTER AND SALFORD.

To the Editor of THE LANCET.

SIR,—In THE LANCET of March 26th you refer to Provident Dispensaries as institutions of a public character with which several medical men are connected, and to which the working classes subscribe. It is time that publicity was given to what they really are, and to the manner in which they are conducted here.

About five years ago, in conjunction with five others, I was surgeon to a provident dispensary. It was quite an exception when the rules with regard to the admission of members were carried out, and when the members of the medical staff complained they were told that if these rules were enforced it would make the dispensary unpopular. THE LANCET is mistaken in imagining that these places are worked by any surgeons in the district who like to join. That was the case formerly, but not now. A doctor is engaged by the committee. He takes a private house in a district remote from the dispensary, so that his future private practice may not be injured. Handbills publishing his name and *private* address are circulated in the neighbourhood, and by means of a collector the private patients of the other doctors are canvassed and pressed to become members. As a matter of fact I can point to numerous instances of shopkeepers who are being attended at a provident dispensary. But what can be expected of an Association the President of which dared to state at a public meeting held in support of these places that doctors in Manchester kept black lists, and were frequently the means of bringing persons to the workhouse? *Theoretically* a philanthropical and generous scheme, at its commencement equally generously supported by the general practitioners; *practically* a scheme which has deliberately broken faith on every point with the medical men, and which is worked entirely on the principle of success, no matter at what cost of honourable and straightforward professional dealing.—I am, Sir, yours faithfully,

Broughton, Salford, April 13th, 1881. G. HOLTBY PINDER.

THE SIGNIFICANCE OF DESQUAMATION.

To the Editor of THE LANCET.

SIR,—I have noticed lately a very important discussion in your columns on the subject of desquamation after scarlet fever. My view of that subject is that the variation in the process itself is some excuse for the variety of opinion as to its duration which obtains in the profession. May I draw your attention to another cause of desquamation, as it seems to me—the administration or use of certain drugs, such as turpentine, perhaps copaiba, &c.? It would be extremely interesting to learn the experience of your numerous readers in regard to this point. I lately attended a gentleman in a large hotel for somewhat persistent hæmaturia, to which he had been liable for about twenty years. Gallic acid having failed, I gave oil of turpentine. Marked desquamation in large flakes of the skin of the hands followed, which suggested a scarlatinous element so strongly that he was detained on account of it, and disinfecting precautions were taken. The question was very important, involving questions of detention, and expense, and sanitary law. There was absolutely no other sign of scarlatina, which was indeed almost excluded by the history of the case, a very slow pulse, normal temperature, &c. I have seen two or three other cases more or less similar, with the particulars of which I need not trouble you, but we have a good deal to learn yet about desquamation. Your obedient servant,

March, 1881. VIGILANS.

"MISSED LABOUR."

To the Editor of THE LANCET.

SIR,—Reading the discussion on so-called "missed labour" at the meeting of the Obstetrical Society, I was reminded of a case I had a few years ago. A woman, aged about forty-five years, who had had six or seven children, consulted me as to her health. She said she was six months pregnant, had quickened six weeks ago, and had felt the movements of the child up to a few days ago, when they ceased, and she began to feel "out of sorts," complained of coldness and weight at the bottom of the body, loss of appetite, and general malaise. The abdomen appeared as large as that of a woman six or seven months advanced in pregnancy. She looked sallow, almost jaundiced. A short course of medicine soon removed these ailments, and she seemed quite well. I did not see her again until about two months after, when she said she was very well, and looked so. The abdomen was so much less that any enlargement could scarcely be seen, and she expressed a doubt as to having been pregnant at all, but thought it was "the change of life." She still felt a little weight at the bottom of her body. I told her I was sure she was pregnant, and would soon part with a dead child. However, time passed on, the natural period of gestation ended, and nothing came of it, and it was not until the lapse of *eleven months* from the beginning of pregnancy, or *five months* from the time when I first saw her, that she sent a hasty message for me, saying that, as she "was walking across the bedroom floor, her inside began to come out." I found her laying on the floor, half fainting, the unbroken bag of membranes protruding, which I removed, and liberated therefrom a six months' fœtus, withered and mummified. The placenta came away, of course, still attached to the membranes. Scarcely any blood was lost, and she quickly recovered. As such cases are not very common, I thought it might be worth while to record this.—I am, Sir, yours faithfully,

W. M. BURMAN, L.R.C.P. Lond., &c.

Wath, Rotherham, April 11th, 1881.

ABERDEEN.

(*From our own Correspondent.*)

THE outbreak of milk poisoning referred to in my last communication is now subsiding, no fresh families having been attacked last week, and very few new cases having occurred in families already affected. The stoppage of the supply of milk has effectually checked the spread of the disease,—an additional proof, if any had been required, that the milk was the cause of the outbreak. Careful inquiries made by the officials of the sanitary staff have shown that out of 110 families supplied from that dairy, 90, comprising probably about 300 individuals, have been attacked. As formerly mentioned, the sudden and severe onset of fever, and the great prostration which followed its subsidence, were the most marked of the constitutional symptoms; and it has turned out that this prostration has been the source of danger. Three deaths have occurred, all of old people—over seventy—in whom the prostration was never rallied from. Each of these fatal cases lasted from eight to nine days. Several other cases looked for a time very serious; but all seem now to be progressing towards convalescence. The local symptoms, as formerly mentioned, consisted in enlargement with tenderness of the lymphatic glands of the neck, first of those close to the angle of the jaw, and afterwards (if the disease continued) of those farther down in the upper triangle of the neck, and in some cases also of those in the lower triangle. The thoracic and abdominal glands were unaffected. Each fresh invasion of glands was marked by a sharp paroxysm of fever, lasting from twelve or twenty-four to forty-eight hours; thus giving rise to "relapses" separated by intervals of one or more days. The most common course has been two attacks, corresponding to the invasion of the two sides of the neck, with one two-days' interval between them; but in many cases the febrile paroxysms have recurred repeatedly, every second or third day, each attack accompanied by and corresponding to, the swelling and tenderness of a gland or glands in the neck further down than those previously affected. The swelling of the glands slowly subsided, and final convalescence was marked by the complete disappearance of the glandular swellings. The tissues around the glands did not seem to be affected, and in no case (as far as known) has suppuration occurred. A large proportion of those attacked were young persons, who seemed to throw off the disease comparatively easily; but middle-aged or elderly people when attacked, appeared to suffer more heavily. In one of the fatal cases a post-mortem examination was obtained; but, having been delayed until decomposition had begun, and having had of necessity to be somewhat hurriedly made, the result was not entirely satisfactory. With the exception of chronic affection of the kidney of old standing, insufficient to account for death, but sufficient to explain why the system could not stand the prostration following such a shock, nothing definite was discovered. The tonsils, lymphatic glands, and blood were reserved for microscopic examination; but as the tenderness and swelling had subsided before death, and as in fact death seemed to be due more to the prostration following disease than to the disease itself, it is hardly to be expected that microscopic examination will throw much light on the matter. The abdominal lymphatic system and the spleen were entirely unaffected.

In my last communication I mentioned that the disease had broken out suddenly on the 1st of April. It appears, however, on further inquiry, that for one or two weeks at least prior to that date there had been stray cases of this affection, all in families receiving milk from the same source; but which, from the novelty of the disease and the short period of its continuance, had at the time been overlooked. The full lists of cases and dates have not yet been received, but from those obtained it appears that the outbreak extended from at least March 25th to April 11th. Pretty extensive inquiries made in various places in Scotland have failed to show the existence of the disease elsewhere.

Although it is impossible now to reproduce the exact conditions which existed at the commencement of the outbreak, and also impossible satisfactorily to examine or experiment with the milk, yet, from what has been learned, it appears that the morning's milk was the worst and the evening's the best; that skimmed milk had less effect than sweet milk or cream; and that boiled milk had still less effect.

As to the nature of the disease, the most reasonable view seems to be that it is the result of an organic poison, of a nature similar to that which produces typhoid fever, which, entering the system by the mouth or fauces, spends its local action on the neighbouring lymphatics. As there is nothing about the cows or their surroundings to account for the outbreak, the condition of the water-supply seems the most natural source to look to, and, as I mentioned in my last communication, the water used in and about the dairy has been shown to be highly contaminated with organic matter. The following is the analysis:—

	Grs. per gallon.	Parts per 1,000,000
Total solids, containing	4·7	.... 67 143
Chlorine	—	.... 10·143
Free ammonia	—	.... 0·029
Albuminoid ammonia	—	.... 0·212
Nitric anhydride	—	.... 3·857
Sulphate of lime, carbonaceous matter, &c.	—	.... 52·902

The analyst adds this note:—"The contamination which the water has suffered in this case takes it from the 'excellent' into the 'dangerous' class. While the harmless ingredients remain at nearly the same point the injurious ingredients have been trebled."

With water of such a character as this used exclusively and continuously in the dairy, is it any matter of surprise that an outbreak should result? Is it not rather a matter for congratulation that no worse results have happened?—and is it not one other added to the many warnings we are constantly receiving that while pure water and pure milk are amongst the most easily obtained necessaries of life, being furnished by nature in a condition capable of sustaining health, yet by our own perversity and carelessness we can only too readily convert them into deadly poisons?

GLASGOW.

(*From our own Correspondent.*)

THE struggle which has been going on for the medical officership to the Scottish Provident Institution has resulted in the appointment of Dr. G. T. Beatson to the office. I understand that the canvas for this place was very keen, and that the disappointment now felt in some quarters is correspondingly great; few, however, will be disposed to grudge Dr. Beatson his success.

Dr. G. P. Tennent has obtained the new physicianship to the Western Infirmary.

Dr. H. C. Cameron leaves the Royal Infirmary, having been appointed surgeon to the Western. In thus having an outsider passed over their heads the dispensary surgeons feel somewhat disheartened, and fancy they have a grievance against the managers of the institution; having borne the drudgery of dispensary work, they not unnaturally think themselves entitled to the ward appointments. The managers, however, have doubtless been actuated by a desire to do the best they could for the great charity under their care. Dr. Cameron has resigned his appointment as examiner in surgery at the University. The withdrawal of Dr. Cameron from the Royal Infirmary renders vacant the post of surgeon to the infirmary and the lectureship in surgery in the medical school attached to the institution.

For the former post Mr. H. E. Clark and Dr. D. Foulis are mentioned as the most prominent candidates; both are excellent surgeons, and the interests of the Royal would not suffer were either appointed. Dr. W. McEwen is spoken of as the most likely candidate for the lectureship.

In the burgh of Hillhead, adjoining Glasgow, one of Ransome's patent disinfecting stoves has been fitted up for the use of the ratepayers. With the exception of one in Greenock, this is the only apparatus of the kind in use in Scotland.

At the annual general meeting of the subscribers to the Glasgow Dispensary for Skin Diseases, it was stated that during the past year 1192 new cases had been treated, making upwards of 23,000 since the opening of the dispensary. Eighty-four of the more important cases had been sent to the ward for cutaneous affections in the Western Infirmary.

The happy manner in which the proposed compulsory reporting of infectious diseases would work in Glasgow was well illustrated a few days ago. Dr. Russell thus refers to the case in his last report to the Town Council:—"During the fortnight we have registered the first case of genuine small-pox which we have seen in Glasgow for seven months. The patient was a seaman who had sailed between Calcutta and London in a ship in which small-pox appeared during the voyage. He left the vessel at London and came down to his home in Glasgow. Feeling ill on his arrival, a doctor was at once summoned, the disease detected, one of those blank certificates which I recently submitted to the committee filled up and posted, and the patient removed to hospital before he had been twenty-four hours in the city. I do not anticipate that any secondary cases will arise from this."

Obituary.

WILLIAM HARDWICKE, M.R.C.S. ENG.,

CORONER FOR CENTRAL MIDDLESEX.

AFTER a tenure of upwards of six years of the office of Coroner for Central Middlesex, Dr. Hardwicke died suddenly on the 14th inst. Whilst engaged in holding a number of inquests at Islington Dr. Hardwicke was seized with symptoms of cerebral hæmorrhage, and struggled sufficiently against them to complete the duties in which he was occupied. When conveyed to his house at Paddington he was seen by Dr. Danford Thomas and Dr. Westmacott, and the aid of Dr. Buzzard was soon after obtained. He was then in a comatose condition, with complete hemiplegia of the left side, evidently dependent upon cerebral hæmorrhage. The symptoms of apoplexy increased, and he died at 2.30 A.M. on the following day. Dr. Hardwicke was sixty-four years of age. Almost up to the time of his seizure he had enjoyed good health, though there had been a slight warning a few weeks previously in the shape of numbness of the left hand. There was a family proclivity to apoplexy, his mother and brother having succumbed to the same disease. It is curious that Dr. Hardwicke had more than once expressed the opinion that he should die, like his brother, the well-known medical publisher, of apoplexy. Dr. Hardwicke's loss will be severely felt.

ROTUNDO LYING-IN HOSPITAL, DUBLIN. — The Secretary of the Public Health Committee of the Corporation has recently drawn attention to the sewerage of this hospital, and has pointed out that the sewer into which the general sewage of the hospital is conducted is at all times, but more especially during high water, when its outlet is closed, charged with sewage gas, from which it can only escape through an imperfectly closed door which partially secures the opening between it and the drain which conducts the sewage from the hospital. The head of the sewer is about thirty feet from one of the principal doorways of the basement of the hospital, towards which the foul exhalations from it find their way through the door referred to. The breadth of the floor of this sewer is so great as to render its flushing by water impossible. Mr. Boyle suggests that a twelve inch pipe should be substituted for the present outfall, and that the existing sewer be filled up throughout its entire length.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — The following gentlemen having passed the required examination for the diploma were duly admitted Members of the College at a meeting of the Court of Examiners on Tuesday last:—

Awdry, Walter Robert, Kidderminster.
Beyer, Henry Gustav, M.D. New York, Washington, U.S.
Black, William Gladholm, South Shields.
Cox, James, M.D. Melbourne, Melbourne, Australia.
Eames, William, L.R.C.P. Edin., St. John's, S.E.
Holberton, Henry Nelson, L.R.C.P. Lond., Hampton.
Howe, John Ernest, B.A. Cantab., Knowle.
Jennings, —, L.S.A., Malmesbury.
Kaeser, Jean, M.D. Bâle, Avenue-road.
Kelly, Thomas, M.D. McGill University, Ontario.
Oswald, Robert J. W., L.R.C.P. Edin., Kennington-road.
Palmar, Edward Talbot, L.S.A., Southsea.
Platt, Walter Brewster, M.D. Harvard Univ., Boston, U.S.
Pomfret, Henry Waytes, L.S.A., Hollingworth.
Potter, Edward Furniss, Knaresborough.
Shelswell, Oscar Berridge, L.R.C.P. Lond., Sibford, Oxon.
Stokes, Lennard, Lee, Kent.
Thornson, Wilfred Burrell, Ledbury-road.
Trotter, Walter Octavius, Stockton-on-Tees.
Walsh, J. H. Tull, Cheltenham.
Wells, Alfred Ernest, Brixton.
West, John Arthur, Bickley-park.
Wight, Ernest Octavius, Clarendon-road.

The following were admitted Members of the College on Wednesday last:—

Branthwaite, Robert Welsh, L.S.A., Willesden.
Browne, Oswald Auchinleck, M.A. Cantab., Lympstone, Devon.
Cory, William Howard, Bath.
Downing, Charles, Falmouth.
Hallowes, Herbert Chaworth, Chesterfield.
Hatton, Edwin Fullarton, M.D. Toronto, Peterborough, Canada.
Knowling, Ernest Mansford, B.A. Cantab., Wellington.
Luscombe, Thomas B., L.S.A., Hampton.
Maddison, William Thomas, Cardiff.
Makeham, H. W. Payne, L.S.A., Chelmsford.
Osborne, H. Rochester, L.S.A., St. Ives, Hunts.
Pearce, Walter, L.R.C.P. Lond., Maidenhead.
Row, Frederick Everard, Devonport.
Shaw, Frank Herbert, Hastings.
Stephens, Guy Neville, Lincoln.
Sturridge, Peter Frederick, Jamaica.
White, Percy Harry, M.B. Edin., Norwich.

The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners on the 13th and 14th inst.:—

Alfred E. Hind, Thos. H. White, Charles B. Leaver, Samuel Stephens, James N. Vogan, and Albert Gresswell, St. Bartholomew's Hospital; Charles W. Biden, Charles Josling, and John J. Rowland, Charing-cross Hospital; Arthur W. Clark and William Watson, Guy's Hospital; William W. Robson, George W. Ford, Thomas Johnston, Walter B. Tomson, and Goolden Perrin, St. Thomas's Hospital; Charles T. Street, Charles J. Weller, and Clement S. Robinson, St. George's Hospital; Harry Littlewood, Thomas Wilson, and Frederick A. Dixey, University College; Thomas Wholey, London Hospital; Jas. R. Roberts, Middlesex Hospital; Albert W. Mitchell, Trevor Webster, Thomas Short, and Clifton Sturt, King's College; Charles D. Green, John L. C. Cox, Duncan B. Irving, and Frederick Bryan, St. Thomas's Hospital; Robert Caldwell and Charles S. Humphreys, Westminster Hospital; John Powell, Arthur H. Mason, and W. H. Brown, University College; Frank Percival, St. George's Hospital; Francis B. W. Phillips and William C. Blight, Guy's Hospital.

Of the 214 candidates examined during the last fortnight, 37 failed to satisfy the Board of Examiners, and were referred for three and 2 candidates for six months' further anatomical and physiological study.

[In the list published last week of gentlemen who passed the Primary Examination, the name "Charles H. Hall" should have been C. H. Hale.]

UNIVERSITY OF EDINBURGH. — The following gentlemen have passed the First Professional Examination for Medical Degrees:—

G. R. Ayshford, E. H. Bannister, John Barrie, G. B. Batten, Alexander Bisset, Ernest Black, J. A. Blair, T. M. Blumenreich, J. N. F. J. Boissière, H. R. Bramwell, G. T. Broatch, R. N. Buist, A. J. A. Campbell, J. G. Cassels, James M. Caw, R. L. Clark, John Cunninghame, A. E. Curtis, Richard Davidson, William Davies, William O. Dow, William Dutton, T. E. Dyson, H. S. Fairbank, W. C. Faulkner, J. E. A. Ferguson, Francisco Fernandes, W. H. Francis, Arthur Fuller, W. G. Galletly, F. W. A. Godfrey, G. B. Goodall, J. A. Haggart, F. W. G. Hall, J. H. Helm, John Henderson, G. V. Hewland, T. M. Hodgson, John Hoyle, John Hutson, E. M. Inglis, R. W. Jamie, J. S. Jones, D. K. Keith, Jas. Kerr, F. H. Knaggs, James Lamrock, A. E. G. Langschmidt, J. A. Lestrade, H. S. Lloyd, J. S. M'Cracken, George Mackay, J. S. M'Laren, Andrew M'Lennan, Jas. M'Leod, Jas. Macpherson, Adam Macvie, Alex. Menzies, W. J. van der Merwe, Gustave Michael, George Miller, R. S. Miller, David Milligan, S. C. Mitchell, G. P. Nicolet, Joseph Nielson, John Noble, F. B. O'Flaherty, A. M. Paterson, C. E. Paterson, R. J. Paton, A. W. G. Price, O. R. Pughe-Owen

A. S. Purves, Wm. Richards, W. G. Roberts, J. B. Robinson, Chisolm Ross, A. J. T. Roux, H. D. Rowan, C. F. D. Shaw, Herbert Shelmerdine, L. G. Smith, S. H. A. Stephenson, W. M. Sturrock, G. P. Taylor, George Thomson, C. G. Thorp, John Tomlinson, S. C. Townsend, C. G. Traill, E. M. Tyrrell, Edmund Vaudrey, T. W. E. Waddington, Joseph A. Wake, N. H. Walker, John Walther, E. H. Warner, Algernon Westlake, J. B. Wilkinson, John Williamson, S. H. Wilson, T. N. Wilson, A. J. Wood, George B. Wood, G. A. H. Woodforde, W. S. R. Woodforde, J. W. Wyncoll, Peter Yates, J. H. Zepero.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on April 14th:—

Batterham, John W., Maitland Park Villas.
Luscombe, Thomas Benjamin, Hampton, Middlesex.
Oakley, John Lewis Bagnall, Newland, Gloucester.
Stott, Hugh, West Kensington Park.
Whistler, Charles Watts, Ashburnham, Sussex.
Harvey, Fredk. W., Cromwell House, Gunnersbury.

The following gentlemen also on the same day passed the Primary Professional Examination:—

John Kenaz Goodall, Charing-cross Hospital; Arthur Augustus Lipscombe and Henry Frederick Iliewicz, London Hospital.

College of Physicians in Ireland.—During the April examinations the following obtained the licences in Medicine and Midwifery of the College:—

Medicine.—Hope Bridges Adams, Charles Dillon Barrett, John Geo. Cronyn, Patrick Arthur Daly, Charles B. Gaffney, William Gem, Wm. Henry Holden, John Laird, John Vincent Lentaigne, Edward Hayes M'Laughlin, Alice Kyme Marston, Isabella Mears, John O'Halloran, Vincent Adolphe Passanha, Francis John R. Russell, Edith Shove, William John Trotter.

Midwifery.—Hope Bridges Adams, Charles D. Barrett, John George Cronyn, Patrick Arthur Daly, C. Burke Gaffney, W. Henry Holden, John Vincent Lentaigne, Edward Hayes M'Laughlin, Alice Kyme Marston, Isabella Mears, Francis John Roberts Russell, James Quirke, Edith Shove.

The under-mentioned have been admitted Members:—

Wilberforce Arnold; Samuel Browne; Charles Edw. Dwyer, Surgeon, Army Medical Department.

Dr. J. H. Aldridge has been placed on the Commission of the Peace for the borough of Southampton.

The Earl Cadogan has been elected to the Presidency of the Chelsea Hospital for Women, which office had become vacant by the death of the Earl of St. Germans.

An application has been made by the authorities of the Preston and County of Lancaster Royal Infirmary for a grant towards the endowment to the institution out of the bequest of £200,000, for charitable purposes, by the late Mr. E. R. Harris, late prothonotary of Lancashire.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest.*

Atkin, C., L.R.C.P.L., M.R.C.S.E., has been appointed House-Surgeon to the Liverpool Eye and Ear Infirmary, vice J. Rose, L.R.C.P.L., M.R.C.S.E., resigned.

Bailey, J. B., M.D., L.R.C.S.Ed., has been appointed Medical Officer for the Sixth District of the Maidstone Union.

Buchan, G., M.B., C.M., has been appointed Surgeon to the Ironstone Workers of the Busbie Colliery, belonging to Messrs. James Dunlop and Co., of Clyde Iron Works.

Carter, R. W. F., L.R.C.P.Ed., L.F.P.S.G., has been appointed Medical Officer for the Workhouse of the Dulverton Union, vice Robinson.

Chadwick, W. F., M.R.C.S.E., has been appointed Medical Officer for the Second District of the Oldham Union.

Davies, B., M.D., F.R.C.S.E., has been reappointed Medical Officer of Health for the Newport Urban Sanitary District.

Dickinson, W. M., M.B., L.R.C.S.Ed., has been appointed Medical Officer of Health for the Shire of Mount Rouse, Victoria.

Dobbyn, W. A., M.R.C.S.E., L.A.H.D., has been appointed Resident Surgeon to the Beechworth Hospital, vice Moussé, deceased.

Doyle, C. W., M.B., C.M., has been appointed Medical Officer for the Sixth District of the Norwich Union.

Harris, A., M.B., C.M., has been appointed Medical Officer for the Dalston District of the Carlisle Union.

Kiernan, L., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Harrow District of the Hendon Union.

Malone, M. J., M.D., F.R.C.S.I., has been appointed Consulting Physician to Barrington's Hospital, Limerick.

Mason, S. B., L.R.C.P., L.F.P.S.G., L.S.A.L., has been appointed Medical Officer and Public Vaccinator to the Pontypool District of the Pontypool Union.

Murrell, W., M.D., M.R.C.P.L., M.R.C.S.E., has been appointed Lecturer on Materia Medica and Therapeutics at the Westminster Hospital, vice Phillips, resigned.

O'Connor, M. R., M.D., M.Ch., has been appointed Visiting Physician to Barrington's Hospital, Limerick.

Ogilvie, L., M.B., C.M., has been appointed Lecturer on Zoology and Comparative Anatomy at the Westminster Hospital, vice Carter Blake, resigned.

Pratt, R., M.R.C.S.E., L.S.A.L., has been appointed Resident Medical Officer to the Royal United Hospital, Bath.

Row, F., M.D., L.R.C.S.Ed., L.S.A.L., has been appointed Medical Officer for the Clowance St. John District of the Stoke Damerel Parish.

Snowball, W., M.B., B.Ch., L.R.C.S.Ed., has been appointed Honorary Surgeon to the Melbourne Hospital for Diseases of Children.

Stocker, C. J., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer to the Plashet Industrial Schools, St. George's-in-the-East, vice Levick, deceased.

Sutherland, J. A., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Acting Resident Surgeon at the Melbourne Hospital.

Warren, W., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Resident Surgeon at the Geelong Hospital, vice Scott, resigned.

White, J. A., M.R.C.S.E., L.S.A.L., of Pendleton, has been appointed Certifying Surgeon under the Factories Act, vice Davies, deceased.

Births, Marriages, and Deaths.

BIRTHS.

Chetwood.—On the 15th inst., the wife of William Chetwood M.R.C.S.E., of King-street, Finsbury-square, of a daughter.

Coward.—On the 9th ult., at Queen-street, Huddersfield, the wife of Frank A. Coward, L.R.C.P.Ed. &c., of a son.

Duke.—On the 8th inst., at 9, Cornwall-road, Westbourne-park, W., the wife of G. Amos Duke, M.R.C.S.E., of a son.

Evans.—On the 11th inst., at Fronheulog, Fourcrosses, Festiniog, North Wales, the wife of R. D. Evans, L.R.C.P.Ed., L.R.C.S.Ed., of a son.

Farrington.—On the 15th inst., at The Moat, Penshurst, the wife of W. H. Farrington, M.D. (prematurely), of a son, stillborn.

Hoar.—On the 12th inst., at Maidstone, the wife of Charles E. Hoar, M.D., of a daughter.

Muirhead.—On the 16th ult., at Gellahating, Assam, the wife of William Muir Muirhead, M.D., of a daughter.

Phelps.—On the 10th inst., at Highbury, the wife of A. M. Phelps, M.A., M.B., of a son.

Rigby.—On the 2nd inst., at Winckley-square, Preston, the wife of J. A. Rigby, Esq., M.D., of a son.

Rushbrook.—On the 15th inst., at Seven Sisters-road, Holloway, the wife of Henry George Rushbrook, L.K.Q.C.P.I. & L.M., of a daughter.

MARRIAGES.

Stott—Gurr.—On the 19th inst., at St. Michael's, Paddington, Hugh Stott, M.R.C.S.E., L.S.A.L., to Ellen, youngest daughter of the late A. J. Gurr, of Shepherd's-bush.

Tweedy—Mack.—On the 20th inst., at St. Paul's, Canonbury, by the Rev. William McCall, Vicar of St. George's, Tufnell-park, N. (uncle of the bride), George, second son of George Tweedy, of Bishop Auckland, to Rosa Courtney, eldest daughter of Robert Mack, Surgeon, of Canonbury, N. No cards.

Wilson—Balfour.—On the 9th inst., at St. John's, Edinburgh, by the Rev. T. J. Nunns, M.A., assisted by the Rev. D. Sandford, LL.D., Robert Morrison Wilson, M.D., of Old Deer, Aberdeenshire, to Charlotte Mary (Sissy), only daughter of the late Charles Anthony Balfour, Lieut. Royal Artillery.

DEATHS.

Alexander.—On the 12th inst., at Eastbourne-terrace, London, Mary Alice, widow of Thomas Alexander, C.B., late Director-General of the Army Medical Department, and eldest sister of T. Heath Haviland, Lieutenant-Governor of Prince Edward Island, Canada.

Chadwick.—On the 7th inst., at his residence, Butterworth Hall, Milnrow, Lancashire, John Chadwick, M.D., L.R.C.S.Ed., L.S.A.L., aged 66.

Charsley.—On the 17th inst., at Graham's Town, South Africa, W. P. Charsley, M.D., late Principal Civil Medical Officer, Ceylon, only son of the late William Charsley, Esq., of Her Majesty's Exchequer, aged 56. (By telegram.)

Hardwicke.—On the 15th inst., at Richmond Villa, Paddington, Dr. William Hardwicke, of Holders-hill House, Hendon, Coroner for Central Middlesex, aged 64.

Innes.—At High-street, Forres, N.B., John George Innes, L.R.C.S.Ed.

Jarvis.—On the 3rd inst., at his residence, Lea Side, Harrow, George Harvey Thompson Jarvis, M.R.C.S.E., L.S.A.L., aged 58.

Kirkman.—On the 11th inst., at his residence, Courtland-terrace, Kensington, John Moss Kirkman, M.R.C.S.E. &c., late of Ardwick-green, Manchester, aged 69.

Philp.—On the 2nd inst., at Brighton, Francis Richard Philp, M.D., in his 82nd year.

Shewan.—On the 16th inst., at Princes-square, Bayswater, Alexander Shewan, Deputy Inspector-General of Hospitals, Indian Medical Service (Retired List).

Stephens.—On the 12th inst., at his residence, Warwick Villa, Abbotsford-road, Redland, Henty Oxley Stephens, M.D., M.R.C.P., aged 75.

Waller.—On the 14th inst., at Spendhurst, Gipsy-hill, Thomas Waller, M.R.C.S.E., Retired Surgeon-Major, Bombay Medical Service, aged 76.

Waylen.—On the 10th inst., at Culver-street, Colchester, Edward Waylen, for twenty-nine years Surgeon to the Essex Rifles Militia.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, April 25.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. — Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M. ; on Tuesday, 9 A.M.

HOSPITAL FOR EPILEPSY AND PARALYSIS, Regent's-park.—5 P.M. Dr. Julius Althaus "On Recent Researches in the Pathology and Treatment of Cerebral Paralysis."

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. R. J. Lee, "On the Special Character of Cutaneous Diseases in Infants and Young Children."—Dr. Allen Sturge will exhibit Two Patients illustrating some interesting points in connexion with Muscular Atrophy.—Dr. Gilbart Smith will exhibit Photographs of the Machines used in the Mechanico-therapeutic Institution of Stockholm.

Tuesday, April 26.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

ROYAL INSTITUTION.—3 P.M. Professor Dewar, "On Non-Metallic Elements."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Dr. George Thin, "On an Unusual Case of Warty Growths on the Face."—Dr. Champneys' Second Communication "On Artificial Respiration in Stillborn Children; Expansibility of various parts of the Lungs."

Wednesday, April 27.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN. — Operations 2½ P.M.

Thursday, April 28.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL. — Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

ROYAL INSTITUTION.—3 P.M. Professor Tyndall, "On Magnetism."

Friday, April 29.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—8 P.M. Professor Blackie, "On the Language and Literature of the Scottish Highlands."

Saturday, April 30.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Professor H. Morley, "On Scotland's Part in English Literature."

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

THE VEGETABLE CELL.

AT a late meeting of the Edinburgh Botanical Society, Mr. J. M. Macfarlane read a paper "On the Structure and Division of the Vegetable Cell," in which he stated that he had observed within the nucleolus of the cell a body which he proposed to call the nucleolo-nucleus, and of whose behaviour in the process of cell development he gave a somewhat detailed account. Professor Dickson said that, whereas division of the cell was known to be preceded by division of the nucleus, Mr. Macfarlane carried the matter further back, and showed that division of the nucleus was preceded by division of the nucleolus; and that, again, although perhaps a little additional observation was still required, he believed to be preceded by the division of the nucleolo-nucleus. It might be a question whether the nucleolo-nucleus was the most important factor, or whether it might be subordinate to the nucleolus or the nucleus; but if the matter was as Mr. Macfarlane showed, that all went to show the probability or possibility of this newly-discovered structure proving of very great importance.

Mr. David Edgar Flinn's question had escaped our notice. We certainly think there is no district in which there is more need of a well conducted medical defence association than that of Birmingham, which on former occasions has done good service in the cause of medical reform.

CAUSE OF DEATH?

To the Editor of THE LANCET.

SIR,—Kindly allow me space in the next issue of your valuable journal to submit to the notice of your readers a few notes of the following case of sudden death.

On the 1st of this month, about 9 A.M., I was called to see a schoolboy, fourteen years of age, who had a history of having been suddenly seized at 4 P.M. the previous evening, without any assignable cause, with severe headache, accompanied by sickness and vomiting. Upon my arrival I found the patient lying partially on his face, with his back turned to the light, complaining of intense pain in the head and a feeling of nausea. When asked a question he showed marked signs of irritability and disinclination to be disturbed. His pulse was high and bounding; temperature 103°; tongue dry; scalp hot; his pupils contracted, and there was marked photophobia.

I diagnosed acute encephalitis; prescribed perfect rest and quiet, exclusion of light, and the application of cold cloths to the head; the patient to have milk and water to drink. Ordered a full dose of calomel to be given, and left with a promise to call later on.

At 1 P.M. we were informed that an attack of vomiting followed the administration of the powder which was returned, and that the patient was becoming delirious. A second calomel powder was ordered, and we promised to visit the patient as soon as possible. In a few minutes—twenty-one hours from the first appearance of the symptoms—a messenger came to say the boy was dying. My principal straightway went to see him, and found that the respiration had ceased, his face was purple, and that other signs of asphyxia were present. The pulse was still to be felt at the wrist. Artificial respiration was employed at once, but with no effect, the patient dying in about one minute after his arrival—three minutes from the onset of these last symptoms.

I should be glad if some of your correspondents could suggest to me the immediate cause of death in the above case. Was it due to thrombosis of the pulmonary artery? If so, how was it brought about? Apologising for trespassing on your space,

I am, Sir, yours obediently,

April 18th, 1881 M.R.C.S., &c.

"THE SURGICAL DISEASES OF THE HEAD AND NECK."

THE *Vienna Montags Blätter* states that in M. Edward Albert's work on the above subject, of which the second edition of the first volume has just appeared, there is a passage treating upon narcotics and containing the following anecdote:—When Sir James Simpson proposed the use of chloroform in confinement cases the religious zealots in England got up an agitation against it on the ground of the scriptural curse, "In sorrow thou shalt bring forth children." Sir James quickly answered this party, which even comprised some doctors, with the biblical fact that God narcotised Adam (*immisit soporem*—"caused a deep sleep to fall upon him") when he created Eve out of his rib.

AN ACEPHALIC MONSTER.

To the Editor of THE LANCET.

SIR,—As these cases are not commonly met with, I thought the following might be worth recording. The case occurred in my obstetrical practice on the 6th inst. Being called to attend Mrs. H. S——, a multipara, I found on examination a pouch of membranes projecting through a well dilated os, and had no difficulty in diagnosing a foot presentation. I ruptured the membranes, brought down the foot, and got the labour terminated in a short time. It struck me, however, at the time with what ease the head passed out through the lower outlet, and on examining the fœtus, which showed marked signs of life in moving its body and extremities, though not crying, I found the greater part of the head absent. The body was that of a well-developed female child, and the face, as far up as the lower part of the forehead, was also well formed, with the exception of the eyes, which were preternaturally large and projecting. There was no forehead, the whole of that part of the cranium originating in membrane, and its contents appearing to be absent. The skin and dura mater terminated abruptly with the bones, and the base of the skull supported little else than the pia mater, the cerebrum being wholly or almost wholly absent. There was very little trace of the cerebellum, but the medulla oblongata seemed to be intact.

I may mention that it lived only a few minutes, to the great satisfaction of its friends, who seemed shocked to find that it was not "like the world." As I was not allowed an opportunity of making a dissection, I can furnish no further particulars.

I am, Sir, your obedient servant,

Beith, Ayrshire, April 7th, 1881. C. R. MACDONALD, M.B.

Dr. H. J. Hardwicke is thanked for his communication; but it does not seem to us that the statements of the criminal he mentions are of any value.

Dr. Latham (Cambridge) is thanked.

Junius.—We do not see anything objectionable in the proceeding.

M. D. W. (Dundee).—Professor Moleschott's lecture will be given in whole or in part in an early number.

A Young Practitioner.—1. Barnes, Galabin.—2. Eustace Smith, Meigs.

Dr. T. Robinson.—We cannot promise insertion of the paper.

Mr. J. B. Sealy.—An account of the case will be found in THE LANCET of April 9th, p. 601.

EARLY MATERNITY.

To the Editor of THE LANCET.

SIR,—Those interested in such statistics will find recorded in THE LANCET for 1874 (vol. ii., page 436) an instance of maternity at the age of thirteen years; and in THE LANCET for 1873 (vol. ii., page 852) an instance thereof at the age of ten years and a half. We may set off against these two cases, and the still more remarkable one in to-day's LANCET, the case of a woman being delivered of triplets at the age of sixty-two, recorded in THE LANCET for 1867 (vol. i., page 727).

I am, Sir, yours, &c.,

Penzance, April 9th, 1881. A. B. B.

DRUGGISTS' CHARGES.

To the Editor of THE LANCET.

SIR,—"A Retired Surgeon," in your last issue, states that when he commenced his professional life, in a small country town, forty years ago, surgeons not only dispensed their own prescriptions, but also those of consulting physicians, with very considerable profit and little trouble.

I can assure him that in many parts of England the surgeon is still as much an apothecary as he was forty years ago, and strictly adheres to the above practices. In many towns in Scotland, too, and more especially in the Glasgow districts, the practitioner, often a university graduate, "dispenses" such articles as tobacco, snuff (in half-pennyworths), sweets, bottles of hair-oil, corn-plasters, and such like. He is not above "sending out his own remedies"; he is even sometimes not above sending out the remedies of Professors Holloway and Morison. This certainly does not look like what "A Retired Surgeon" designates as "pride interfering with pocket." The remuneration for this "brain work" goes into the practitioner's pocket.

So that the good old days have not quite gone yet. Why not improve on them, if possible? Why should not the practitioner become more general than ever, and sell ham and butter, or spirits and beer?

I am, Sir, yours truly,

April 15th, 1881. A SURGEON—NOT RETIRED.

FALSE EARS.

IN Paris false ears are a new manufacture for the toilette. Ladies who think they have ugly ears place these artistic productions under luxuriant tresses of false hair, fasten them to the natural ears, and wear them for show. False hair, false teeth, false breasts, false hips, false calves, false ears—what next?

FEES FOR MEDICAL EXAMINATIONS FOR INSURANCE OFFICES.

To the Editor of THE LANCET.

SIR,—I have seen some correspondence in your columns lately on the above subject, and there is one point which has not I believe been touched on, and which, I think, is well worthy the attention of the profession. It is the custom of some offices to give only half a guinea as fee when the proposal is for under some amount (in some offices £300, in some £500). This has always struck me as an anomaly, for surely the medical examination and report are, or ought to be, the same in all cases, whatever is the sum proposed to be assured. I examine for a good number of offices here (perhaps a dozen), and it has been my custom to write a protest to the secretary on receiving my first half-guinea fee, pointing out the inconsistency, and asking on what principle the office acts. I am happy to say that one of my offices last month reduced the minimum amount for the full fee of one guinea from £500 to £300, and that I have had a letter from the secretary of another only this week, saying that "they have pleasure in stating that a fee of £1 1s. will be allowed in all cases in future." This is encouraging, and shows, I think, that if other medical examiners for insurance offices would write similar letters we might soon have a guinea in all cases—not too large a fee, in my opinion, for any such report as most offices demand and, I think, have a right to expect for their own protection.

I am, Sir, yours, &c.,

Halifax, April 12th, 1881. E. WEST SYMES, M.D.

TALIPES AFTER ACUTE RHEUMATISM.—WHAT TO DO?

To the Editor of THE LANCET.

SIR,—I have under my care a girl nine years of age who some three years ago had an attack of acute rheumatism. During convalescence there suddenly appeared lameness, caused by contraction of the tendo Achillis, and since that time the case has remained apparently a simple case of talipes equinus.

I should feel very much obliged if any of your readers could tell me whether or not in such a case section of the tendon would be justifiable or likely to improve the limb. The girl is very well in health now.

I am, Sir, yours, &c.,

April 20th, 1881. E. G. W.

A Subscriber.—We do not know of the existence of such a society.

Mr. William Fraser, M.B.—We are not aware of any such necessity.

Union.—We fail to see that any practical benefit would arise from the adoption of our correspondent's suggestion.

Dry-as-dust.—We have no recollection of the article mentioned.

THE CONTINUED USE OF ERGOT IN SMALL DOSES.

To the Editor of THE LANCET.

SIR,—May I ask, through your columns, if any of your readers can give me information upon the continued use of ergot in small doses, as to how long it may be persevered with without inducing ergotism?

I have a patient who has been suffering for some time past from, I think, aortic obstruction. Four consultants have seen the case, two of them, at least, very eminent men. The advice given has always been to rest upon the iron and digitalis treatment; and this was done and seemed sufficient until lately, when it completely failed, and the patient looked like going altogether to the bad. Dyspnœa became extremely urgent, the action of the heart very tumultuous, and the pulse hardly perceptible. Stimulants appeared to increase the mischief, and all the ordinary remedies proved utterly useless. Anasarca first, then ascites supervened, then œdema of the lungs; and the patient appeared to be moribund, and not likely to last from hour to hour. In this extremity I had recourse to ergot, which had once before in my hands been successful for a time. The preparation used was the ext. ergotæ liq. (P.B.), and the dose given twenty minims every three hours, combined with five minims of tincture of digitalis. In a short time the most marked improvement in the pulse was observable, and in about three days the patient was breathing calmly and sleeping quietly, the pulse being full and soft, and not over sixty. Since then the dropsy has disappeared, and rest can be taken lying quite low in bed; the dose of ergot has been reduced to ten minims every fourth hour, and the exhibition of it has now been continued for three weeks.

In my previous case, as soon as good improvement was established, and the patient could leave her bed for a sofa, the ergot was discontinued, when immediately the whole trouble recurred, and the patient quietly succumbed. I should like now to push the ergot to the furthest possible extent to see if permanent improvement can be established; and I shall be very greatly obliged by any information upon the subject that any of your readers can give.

I am, Sir, yours obediently,

April, 1881. QUÆSITOR.

A NEW OPERATION FOR SOME FORMS OF NEUROMATA.

To the Editor of The Lancet.

Sir,—I hardly know whether I am justified in calling this a new operation, but it is not described in "Holmes's System of Surgery," and I never saw it practised. Holmes says, "The only effectual remedy for these morbid growths is the knife; the operation may consist either of excision of the tumour, with or without a portion of the nerve, or of amputation of the affected limb."

Now, my operation may be called excision of the tumour without a portion of the nerve, but it is not described minutely, and unless the surgeon remembers the pathology of neuromata he will probably not think of it, simple as it is. Let me tell my story. I will first describe an interesting case, in which I must confess that I and a friend of mine made a mistake, and then I will show what lessons I learnt from it. Last summer a man came to our hospital with a large tumour in the position of the median nerve, just below the axilla. There was also a large mass a little above the bend of the elbow, apparently connected with it, but not the same tumour. I supposed that both were enlargement of the median nerve. It was on the left side, and on the same side of the trunk was an immense number of small tumours, chiefly on the chest-walls, which looked like enlarged lymphatics, but I am inclined to think they were connected with nerves. There were about fifty of them, about the size of small nuts. The tumour under the axilla was very painful, and the patient wished this one to be removed.

My medical friend who was with me proposed to perform some operation. I asked him to do this, and promised my assistance and advice. He divided the tissues down to it carefully, and exposed the tumour. It was connected with the median nerve; the nerve was one with it, in fact, above and below, and there seemed to be no way of dealing with it but by removing a portion of the nerve, cutting it above and below the tumour. I had done this a year or so before in the case of a similar tumour, and though the patient lost more or less the use of the arm, he got rid of the pain; so I advised my friend to do the same. He did so. The mass at the bend of the elbow we deemed it wiser to leave alone. There was troublesome suppuration afterwards in the wound, but it finally healed. The man did not lose so much power of the arm as I expected, though it was considerably paralysed. The curious and satisfactory point was that the mass near the bend of the elbow disappeared gradually, and all the small tumours spontaneously disappeared also. We examined the tumour we had removed, and were struck by the way in which nerve fibres completely surrounded the tumour, which was in the centre and almost unconnected with the nerve. It was fibrous in its nature. I looked at Jones and Sieveking's Pathological Anatomy, and found these tumours very clearly described.

I resolved the next time I saw a neuroma to bear in mind the probability of it being what Jones and Sieveking call a false neuroma, which was evidently the nature of the tumour we had removed. In the course of the next six months I had three cases, and I applied the knowledge I had acquired. The first was a tumour on the outside of the leg, connected with the musculo-cutaneous nerve; the other two were in the axilla, and connected with the median nerve. All these three tumours were false neuromata; the nerve fibres had completely formed a covering for the tumour. I simply cut carefully through all the tissues down to the nerve; then hooking it up, I made a longitudinal incision through the nervous covering of the tumour, and turned out the fibrous tumour with the greatest ease, leaving the nerve uninjured except by the longitudinal incision. I stopped the bleeding and closed the wound with a suture or two. All these cases did well; the wound in two cases healed by first intention. In the case of a large neuroma of the median there was secondary hæmorrhage and a good deal of suppuration, but in all cases the wound finally healed, leaving the patient without pain and the nerve quite uninjured, the motion and sensation of the parts supplied being perfectly normal. This may not be a new operation. There is certainly nothing remarkable in it, but it is one of great practical use, and I have not seen it described, so I think the above might be worth publishing.

I am, Sir, yours, &c.,

Kashmir, March, 1881. E. Downes, L.R.C.P. Lond.

Erratum.—In Dr. Robinson's letter on Locomotor Ataxy, in our last issue, page 644, the word printed "parents" should have been "patients."

Croonian Lectures

ON THE

INFLUENCE OF THE CIRCULATION ON THE NERVOUS SYSTEM.

Delivered before the Royal College of Physicians of London,

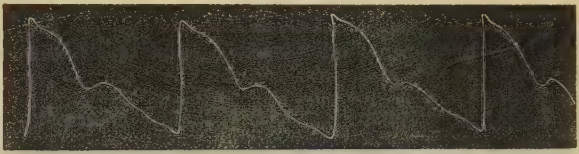
BY WALTER MOXON, M.D. Lond., F.R.C.P.

LECTURE III.—Part II.

The consideration of fainting, epilepsy, and the fatal coma of cerebral exhaustion has confined our attention so far to the influence of the circulation upon the nervous centres. But there are other bearings of the influence of the circulation on the action of the nerves which are worthy of some notice, and the chief of these is the condition known as angina pectoris. Perhaps no complaint has attracted more attention than this singular and painful affection, and perhaps the attention devoted to a complaint has never given rise to so large a record of somewhat incongruous anatomical lesions as causes of the disorder. To select among these in the hope of finding a proximate cause of the angina is not a promising task; for one might well say that every kind of disease of or about the heart has been found as cause of angina pectoris; so that pathologically angina pectoris had become a rather wearisome topic, when new interest in it arose through the clinical observation of its connexion with a certain state of the circulation. No medical discovery in recent years has received a more marked and more just attention than that made by Dr. Lauder Brunton as to the power of nitrite of amyl to relieve angina pectoris; indeed, it stands among a very few instances in which the physiology of a disease has enabled a trained and acute scientific mind to infer successfully the remedial powers of a physiological agent. It is well known that Dr. Lauder Brunton observed that in cases of angina pectoris the tension in the arteries is very high, and that nitrite of amyl, by relaxing the small arteries, reduces the tension and relieves the suffering. But whilst the benefit thus obtained in some cases of angina pectoris is most satisfactory, in other cases it is so utterly awanting that there must be some differences in the cause of the pain corresponding to so great a difference in the effects of the remedy. I will now ask your attention to some facts which may throw light on this difference. I will send round tracings from the pulse of a man who is in Guy's Hospital for angina pectoris, and who is always relieved by the amyl. Afterwards I will send round tracings from the pulse of another man who died of angina pectoris, which never was relieved in the slightest degree by amyl, but in whose case there is some good reason to believe the amyl acted injuriously. The man who obtained relief is in No. 10, Philip ward. He is sixty years of age, and has done no work for eighteen months on account of pain in the chest, which is not constant, yet is present for the most part as a moderate pain. But this pain seizes him at times in a much more severe manner; it then has all the characters of angina pectoris—an excruciating sense of pain and compression of the chest extending through the left shoulder, and down to the fingers of the left hand. This seizure of great pain generally occurs when he is walking. When he has persevered in spite of the pain, he has several times fallen, and been convulsed. Two such convulsive attacks observed in the hospital were seen to be epileptic. (I may remark, in passing, that the epileptic convulsions of this man are more nearly certainly due to anæmia of the brain than in any case I have met with. But the same association of angina with epilepsy has been observed before.) Examination of the heart and great vessels shows evidence of obstruction of the aortic orifice. The man never had rheumatic fever, so that the obstruction doubtless arises from disease of the aortic wall invading the valves.

Dr. Galabin has been kind enough to take these tracings during an attack of the angina, and during the relief which the patient was obtaining from nitrite of amyl. When the paroxysm is at its height the traces show that the heart is labouring against high pressure.

Fig. 1.



Four ounces. Ordinary pulse of G. B——.

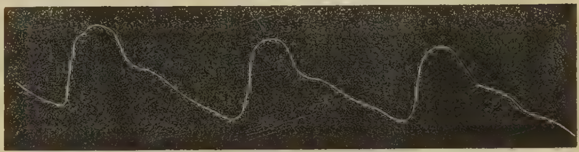
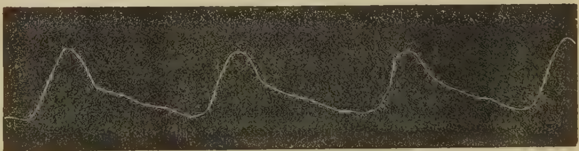
Two ounces. During attack of pain.

Fig. 3.



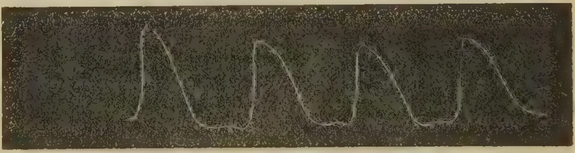
Three ounces. During attack of pain.

Fig. 4.



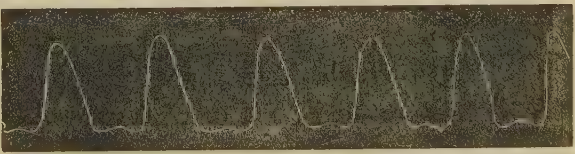
Four ounces and a half. During attack of pain.

Fig. 5.



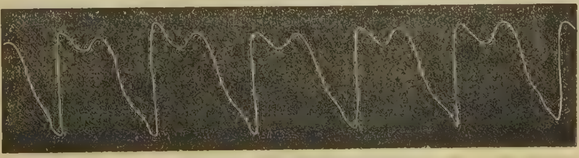
Three ounces. Nitrite of amyl just commenced.

Fig. 6.



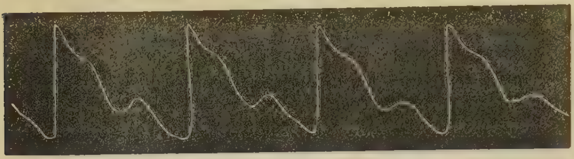
Three ounces and a half. Nitrite of amyl (2).

Fig. 7.



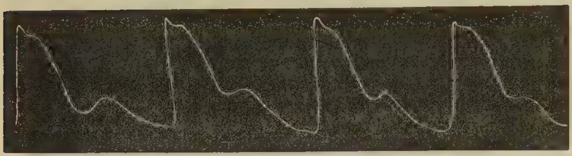
Three ounces. Nitrite of amyl (3).

FIG. 8.



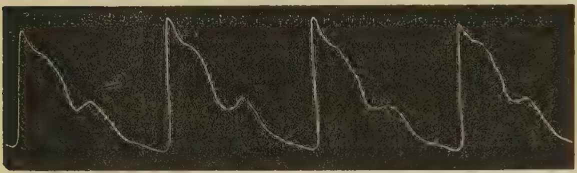
Three ounces. Nitrite of amyl. Pain relieved.

FIG. 9.



Four ounces and a half. Nitrite of amyl. Pain still relieved. Effect passing off.

FIG. 10.



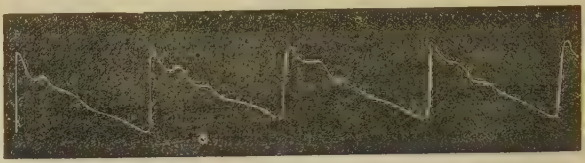
Three ounces and a half. Nitrite of amyl. Effect going off.

This is to be inferred because the pulse bears four ounces and a half pressure, and also because we find a slanting upstroke, a round top, and almost no dicrotic wave. As soon as the amyl begins to act and the pain to be relieved, these signs of "high tension" begin to rapidly pass off, and the pulse trace returns to the condition it usually shows in this man. The relief of the pain goes with evidence of more effectual circulation. But there is some doubt whether this more effectual circulation is brought about merely by reduction of the arterial tension, for the pulse in the natural state bore a rather higher pressure than it would bear during the angina, so that the actual tension appeared rather lower in the paroxysm, and the state of the artery during the paroxysm would be better ascribed to the heart's failing to keep it up to its hard work. The first trace after the nitrite of amyl shows rather slanting upstroke, then deep dip, but slight dicrotic rise. Next trace shows sharper upstroke and more dicrotism. It looks as if the drug first relaxed the arteries and reduced tension, and then a little later stimulated the heart to act more sharply. The trace with the effect of nitrite of amyl going off after the paroxysm is very like the ordinary trace without the drug. It may be observed that the pulse is slower, though the tension is lessened in the attack, so that the cardiac regulating apparatus does not act quite normally.

From this observation it would appear that the pain in angina pectoris occurs in persons whose arterial tension is high. But that the attack of angina does not coincide with an increase of tension; rather, indeed, with a decrease of it. The pain comes on through a temporary, and in fatal cases, a permanent failure of the power of the heart to cope with the high tension in the arteries. And the relief of the pain by amyl comes partly through the nitrite relaxing tension and partly through its stimulating the heart. In short, angina pectoris arises in this man whilst the heart is labouring in vain against an ordinary high tension—that is, through relative failure of the heart against high tension, and as pain occurs with a lower than normal tension, the painful parts must at the time have increased sensibility to such tension. In other words, we must recognise state of nerve as well as strain of vessel among the causes of the pain.

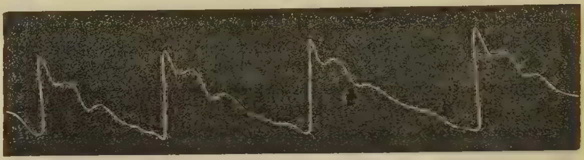
Now my second case, in which amyl did not in the slightest degree relieve the excruciating and overpowering suffering, shows in the pulse trace a very different state of affairs. The pulse in its ordinary condition has characters which appear like those of slightly higher tension than normal—about the degree of increase of tension that one meets with in chlorotic girls. A pressure of four ounces develops the trace best, and the trace offers a marked tidal wave and a slight dicrotic wave. But a pressure of five ounces flattened, and a little more crushed the pulse.

FIG. 11.



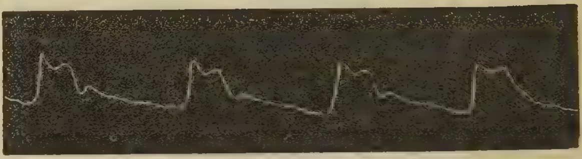
Three ounces. Mr. B——. Ordinary pulse.

FIG. 12.



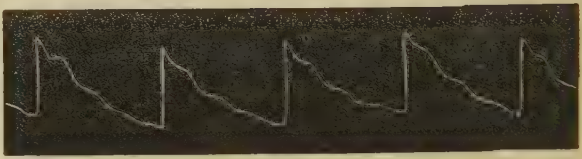
Four ounces.

FIG. 13.



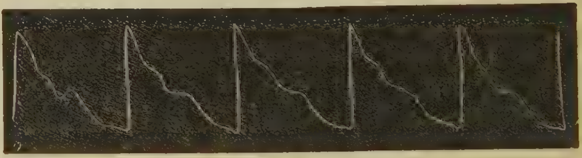
Five ounces.

FIG. 14.



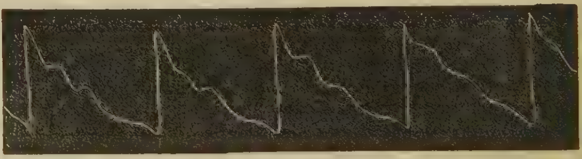
Five ounces. After exercise. Pain felt slightly.

FIG. 15.



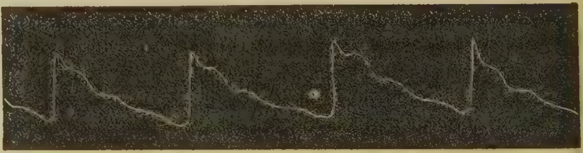
Three ounces and a half. Nitrite of amyl.

FIG. 16.



Four ounces and a half. Nitrite of amyl. Effect passing off.

FIG. 17.



Five ounces. Twenty minutes after nitrite of amyl.

These traces were taken by an authority whose skill in using the sphygmograph and ability in interpreting its writing are I had almost said unequalled. Dr. Galabin, who took these tracings, ascribes the condition of the pulse ather to inelastic arteries than to high tension, concluding this to be the case on account of the sudden crushing of the pulse by a moderate pressure. Now, when the gentleman whose pulse furnished these traces used some effort and produced the pains of which he complained, and when Dr. Galabin took a pulse-trace as speedily as possible, and whilst yet some of the pain remained, it was thereupon found that the pulse showed lower tension than in its natural condition; and when nitrite of amyl was at once administered there was scarcely any effect at all produced by it upon the pulse, hardly any dicrotism appeared, although there was a slight diminution in breadth and increase of height of the tidal wave, and the amyl produced no relief whatever. Shall I be excused for giving full particulars of this case, important as it is from the completeness with which the conditions of it during life and after death were allowed to be observed? The history is as follows:—Mr. B——, civil engineer, forty-two years old, a well-built, healthy-looking man, of younger appearance than his stated age, said that he had been ten years in India. When there had nothing beyond a very slight sunstroke, and "inflammation" of the bladder of a few days' duration, which, however, he said rather brought him down in the way of nerve-power. He got well on the way home, and has been well ever since, until a month ago when going up a hill he suddenly felt a pain which stopped him; the pain went across his chest at the level of the heart, and up the breast-bone, and down the left arm into the fingers. When he persevered in the attempts to walk the pain went up his neck to his jawbone, and seemed to fix his jaws; when he desisted from the effort his pain soon ceased. But since the day when he was taken he finds himself unable to go up a hill without a recurrence of the pain, and latterly it has been more easily brought on, and, in fact, stops him whenever he goes walking—stops him in the most absolute way. The pain is not accompanied by palpitation or any sense of effort of the heart, or fault of the heart's action, that he is conscious of; he ascribes the pain to his liver. There is no tendency to sickness when he perseveres in walking, or tries to do so. He praised his appetite and digestion. Up to that time he had not had a single attack that was not caused by exertion. The possibility of such a thing had not struck him. I examined his heart very carefully, and could not detect any abnormal murmurs. The sounds themselves were rather feeble, the apex beat was scarcely palpable. These conditions were not more evident than is the case in many quite healthy persons. The temporal arteries were not visible, nor were the radial arteries either thick or tortuous. The pulse was, however, slightly visible at the right wrist. This gentleman was advised to take with him in his walks some nitrite of amyl capsules, and when pain appeared to break the capsule and use it by inhalation. Dr. Bosworth of Sutton, wrote to me Dec. 14th: "He still has the pain; he has carefully tried the nitrite of amyl capsules, but they have not the least effect either in abating the pain or preventing its recurrence." Meantime Dr. Galabin kindly took the tracings I have shown. The next I heard of Mr. B—— was on Dec. 23rd, from Mr. Ewen of Exmouth, who said that Mr. B—— had been seized there with an attack of angina whilst in bed. Again, two weeks after that he had had a cerebral attack, including aphasia, and, finally, that Mr. B—— had died suddenly. An inspection was made, and the heart and root of the lungs were sent intact to me by Mr. Ewen for examination. The specimen is here, and it very clearly shows why nitrite of amyl failed to relieve the pain and failed to produce any marked effect at all upon the sphygmographic trace. The heart is of about natural size. Its left ventricle is dilated and the wall is thin. The portion of this ventricle near the apex for about two square inches is changed to a yellow fat-like substance, looking quite unlike muscle; a lesser degree of the change in the form of fibrous degeneration extends around this part, so that but a moiety of the whole substance of the thin wall of this ventricle is free from change. Where the change is most extreme at the apex there was seated an ante-mortem polypus of clot as large as a filbert. This was burst open and its contents partially gone. Microscopic examination showed the yellow leathery substance to be altered muscular fibre. Fully one-third of the ventricle wall was thus destroyed, and the rest was thin, wasted, and flabby.

Now, in this case the symptoms were those of angina pectoris in its most characteristic form, as described by Heberden, and the symptoms were utterly unrelieved by amyl; and when we consider the facts which are beyond doubt in this case, we must see reason to conclude that high arterial tension is not the only or the necessary cause of angina pectoris, even if it be the principal cause.

For the facts are these: First, sphygmographic trace showed rather inelastic arteries than high tension. Second, exertion, which brought on the pain, lowered the tension of the pulse, as shown by the sphygmograph. Third, nitrite of amyl produced very little change in the pulse, as shown by the sphygmograph, and brought no relief at all. And, lastly, the state of the left ventricle, as found on post-mortem examination, showed such extreme wasting and degeneration that it appeared impossible that tension could have been raised by its action, and to confirm this impression an old ante-mortem clot gave evidence of weeks of a passive and stagnant state of the blood in the left ventricle. The condition of the cardiac nerves, which, no doubt, caused the angina, I will presently describe. In short, the doubt as to high tension which the pulse contributed, the nearly certain assurance that there could be no high tension which the heart contributed, and the conclusive evidence that there was no high tension to relieve which the total inefficacy of amyl contributed,—all these sum up to prove that in this case the angina, typical as it was, must have arisen from some other cause than high tension in the arteries.

Let me now show another set of tracings, taken by Dr. Galabin from the pulse of a gentleman who has angina pectoris in a most typical form. In this case the disorder has lasted about two years; some of the attacks have been so severe that recovery appeared hopeless to the medical attendant: so intense was the pain he endured and so great was the consequent prostration. But in the height of the attacks no change was noticeable in the pulse, either in rate or quality. I could not obtain tracings of this pulse during the paroxysm. The tracings taken in the interval, and which are now before you, are thus described by Dr. Galabin:—"The pulse is fully developed by a very low pressure, one ounce and a half, but bears pressures up to three ounces (about the average pressure for a youthful normal pulse) without much change; a pressure of three ounces and a half destroys its characters, as you will see, and a very little more quenches it altogether. The curve differs from that of a perfectly normal soft pulse only in the fact that the tidal (predicrotic) wave commences too early in the descent. I should think that the general conclusion is that the arterial elasticity is in very fair condition, considering the patient's age, and that there is no excess of tension, the pulse being a soft rather than a hard one."

Now, in this gentleman's case the inhalation of nitrite of amyl produced no relief whatever. Injections of morphia were the only means by which the pain could be assuaged. Here, then, we have evidence that in the intervals between the attacks the tension was low. Whilst in the attacks we can infer that there was no high tension, inasmuch as amyl proved of no service whatever; in other words, relaxation of the arteries did no good.

In the series of three cases just related we have, first: a patient with signs of aortic disease whose pulse-trace during the paroxysm gave the characters of high tension and whose pain was relieved by nitrite of amyl, thus showing that the tension was an essential factor in the attack of pain. But, at the same time, it was observed that the tension of the pulse was lower in the attack than in the patient's ordinary condition, so that some other factor than the tension brought on the attack, although lowering the tension took the attack away. Thus, even where the relief of the tension removed the attack the tension is proved to have been but one factor in the causation of the pain. In the second case slight signs of high arterial tension were present in the ordinary pulse, but it was observed that in the pain this tension was lowered, whilst nitrite of amyl was utterly useless. Here we find tension reduced in the attack, as in the first case, but it is not in this case a factor in the production of the pain; relief of tension has no effect. In the third case there is no high tension, but quite the contrary; the pulse is of low tension, and amyl is again utterly useless. In this case tension passes out of sight altogether. The general conclusion is that high arterial tension is not to be regarded as the determining cause of angina pectoris, but as one factor of pain in some cases of angina pectoris; and that whilst it is true that amyl gives relief when high tension is present, there is reason to be cautious in pressing the amyl when it fails, for by lowering tension when already low the amyl may dangerously increase the tendency to stagnation of the blood. And there was evidence in two of the cases that tension was really lower during the pain.

Indeed, the achings which are suffered at the heart are of two distinct kinds, like the achings which are suffered in other parts, say the teeth. In either case there is a kind of ache which is more properly a tenderness of the part, so that it suffers in its ordinary service, as when a tooth cannot chew, or the heart cannot beat, without pain more or less severe. Here, in the case of the teeth, we are able to use the other side of the mouth, or, even if hard driven, to live on liquid diet, and give the tender organs a rest for their recovery. And in the case of the heart, when its work distends the aorta, and causes pain, we can take advantage of what Dr. Lauder Brunton has so well taught us, and can open the distal vessels with nitrite of amyl so as to relieve the tension.

The relief thus given lasts only for a while, and often only for a short while, and it is very desirable if possible to find means of lowering pressure permanently. If the angina pain which is relieved by amyl is caused by the pressure of a bulging aorta, there is a fair prospect of permanently lessening or removing such pain by any measures that would tend to permanently lower general arterial tension. But what means have we of permanently lowering arterial tension? Such a result is not so easily obtained as might at first be supposed. It is natural to think that if blood be drawn the tension in the vessels must be reduced with the loss of their contents. But it has been shown by experiment that this is not the case. Bleeding does not with any certainty, or to any large extent, lower the pressure in the arteries. Neither, indeed, will any attempt to suddenly alter the whole quantity of blood in the body succeed in suddenly lowering arterial tension. Yet it is certainly possible to lower vascular tension by lessening the quantity of liquid in the whole blood mass. This is shown in a rather horribly conclusive way in some experiments of Kussmaul and Tenner, in which they desired to remove the cerebrum, and then to examine the results of further sections of the cerebellum. But they found that all their normal rabbits bled to death before the ultimate conditions for their experiments could be reached. Hereupon the experimenters kept some rabbits on a dry diet of corn, &c., for two weeks, and the effect of this deprival of liquid in the food was so satisfactory, and the blood in the vessels fell to so low a tension, that such a rabbit could have its calvaria and cerebrum cut away, and its occiput and cerebellum mutilated to any desired extent, without dying too soon for Kussmaul and Tenner's purposes. Here we see the power of bleeding and dry dieting crucially contrasted, and the result is to show that the method of Valsalva for the cure of aneurism, so far as it proceeded by bleeding, did not correspond with the most hopeful line; neither, so far as it proceeded by starvation of solids, did it correspond with the most hopeful line. The experiment of Kussmaul and Tenner rather shows clearly that for reduction of blood-pressure it is not necessary to bleed, nor is it necessary to reduce solids in the diet, so far as they are truly solid, and not succulent; but that a very great degree of reduction of tension may be reached by starvation of liquids.

In the Clinical Society's Transactions, vol. iii., there is a case of angina pectoris relieved by nitrite of amyl. It is very ably and carefully reported by Dr. Lauder Brunton, and it shows well the signs of high tension in pulse-tracings taken during the pain, and also the relief of the tension as the amyl came into operation. The pulse was quickened during the attack of pain. The sphygmograph used by Dr. Brunton did not enable him to estimate the degree of pressure upon the pulse. His conclusion was that in this case the attack consisted in spasmodic contraction of some, if not all, of the small systemic, and probably of the pulmonary, vessels, causing great increase of the blood-pressure on both sides of the heart. He remarks upon the fact that with the high tension the pulse becomes quicker, thus showing a derangement of the cardiac regulating apparatus, which should cause the pulse to become slow as the pressure rises. But I believe that unless we can estimate the pressure borne by the pulse one cannot certainly conclude from the pulse-trace that the tension is positively high; all that can be said is that it is high relatively to the power of the heart. So that there may not have been unusually high tension, but rather a failure of the heart to cope with the existing tension, such as Dr. Galabin found in my case. Dr. Brunton concludes that the pain was not originally in the nerves composing the cardiac plexus, but was produced by a pressure of blood upon those of the heart and arteries, and that the pains were of a rheumatic character.

It appears, then, to be exceedingly difficult to decide what was the proximal cause of the pain in these cases; but it is a significant fact that Dr. Brunton's case which was relieved by amyl was one of aortic disease with regurgitation, and my case was also one of aortic disease; and as it was not rheumatic, it was in all probability of the nature of deforming aortitis. Indeed, I believe that it is chiefly for the relief of attacks of anginose pain in aortic disease that nitrite of amyl has come into such general use in our hospitals since Dr. Brunton's valuable discovery was made known, whereas I have been generally disappointed with amyl when there has been no sign of disease of the aorta. Cases of relief by amyl in angina in which there was no evidence of heart disease are recorded, but I do not know of any such cases which have been cleared up by post-mortem examination.

But we have seen that the cases of angina pectoris which are due to high arterial tension form only a part of the whole number, and there are other cases of angina which are more purely neuralgic and are not relieved by amyl, and these latter cases have an altogether different kind of cause. It may be that the pathological change which produces the more purely neuralgic angina is not always the same. But an example of what I have found in many cases to be a very evident cause of the pain is before me now in this specimen, which is the heart in my second case, that of Mr. B——, whose pulse showed reduced tension when under the pain, and whom amyl failed to relieve. The state of the nerve accompanying the anterior coronary artery of this heart is sufficient to account for any degree of pain. In searching for the cardiac nerves, I observed that the aorta was perfectly healthy; it was quite separable from the texture around. The cardiac nerves, in their course between the aorta and pulmonary artery, close to the origin of these vessels, were easily found; and on following them down they were quite natural in appearance, until the anterior branches came to a diseased part of the corresponding coronary artery. Now, the mouths of the coronary arteries were natural, and the anterior vessel was natural for about half an inch, then suddenly became swollen at a bifurcation so as to be thick and white. At the same spot it became impossible to separate the vessel from the tissue around so as to render visible the exterior of the artery. In fact, here dissection of the vessel could not be carried out, and the nerve could no longer be separated from the artery without tearing or cutting the vessel. At one inch from its origin the artery was quite blocked up, and full of pus-like detritus of old clot; the diseased part of the heart's wall corresponded to this part of the artery. Microscopic examination of sections of the vessel showed a good example of deforming arteritis. Whatever was the origin of this patch of inflammation in the artery, it extended to the tissue around, with the effect of causing a dense fibrous change, which involved the branch of the cardiac nerve. In short, the nerve was involved in the inflammatory decay of the artery in the same way as the branch of the dental nerve is involved in the inflammatory decay of a carious tooth.

Let me give one, perhaps, yet more striking case of neuralgic heartache. The most remarkable case of angina pectoris which I have met with occurred in a child of eleven years of age, who used to be seized with onsets of intense thoracic pain when at play. No physical signs of heart disease were found in her. In one of her seizures the child died, and on examining the heart I found the aorta in the first two inches of its length softened, and with almost gelatinous appearance, through subacute inflammation. At the point where the cardiac nerves passed between the aorta and pulmonary artery they were involved in the thickening and inflammation which surrounded the former vessel. Neither the valves nor the coronary arteries were at all involved in the disorder. But the implication of the nerve in the inflammatory disease of the vessel was most obvious, and the pain was as completely explained by the post-mortem appearances, as facial neuralgia is explained by finding an exposed branch of dental nerve. In both these cases the nerve was involved in inflammatory decay of the artery. A similar case of inflammation, including the cardiac nerves, and causing angina pectoris, is given by Lancereaux, and is figured in his Atlas of Pathological Anatomy.

From the foregoing observations it would appear clear that there are two distinct kinds of angina pectoris, one which is a result of tenderness and overstrain of the great vessels. In this kind of pain high tension in the arteries is a factor, although a morbidly sensitive state of the nerves must at the same time be present. Such pain corresponds to pain and tenderness in the teeth during mastication, and it is lessened by whatever will lessen the strain upon the tender parts; so that amyl nitrite, or less certainly nitroglycerine, will bring welcome relief, even when it does not give entire comfort. But the relief thus afforded is apt to be temporary and often only partial. So that even in these cases we have to bring in other means, and supplement the service which the amyl renders in relieving the strain upon the vessel by such further service as morphia can render by reducing general sensitiveness. A second form of angina pectoris is a kind of neuralgic heartache, arising from actual inclusion of a cardiac nerve in the inflammatory decay of an artery, and no signs of high tension in the vessels are present. This disease corresponds with such neuralgic toothache as arises when a branch of the dental nerve is involved in inflammatory decay of a tooth. It is more paroxysmal and violent than the first form, the intervals are more free, and there are usually no signs of disease of the heart or great vessels. The means of relief are those which are found useful in the similar neuralgia of the face, and lead us first to reduce morbid sensitiveness by such improvement of tone in the general health as may be possible; second, to employ such alterative drugs as, like arsenic and quinine, have proved themselves to possess some power of controlling the tendency to neuralgic pain; and, third and chiefly, the use of sufficient quantities of morphia to afford relief in the attacks. Morphia, given in the form of subcutaneous injection, will produce the most satisfactory result in the way of temporary relief of this form of angina pectoris. But angina pectoris does not always arise from organic changes in the heart or arteries. For, like facial neuralgia, it may occur secondarily as a reflected pain whose source is at a distance. The primary disturbance which gives rise to reflex angina pectoris is usually seated in the course of the pneumogastric nerves. A very remarkable example of this occurred in the person of one of the greatest surgeons of our own or of any past time. My late friend and colleague, Mr. Hilton, was attacked three years before his death with severe angina pectoris; so sévere that the cramping thoracic pain would not allow him to walk many steps, and he was obliged to have a cab to go a distance of 100 yards; this pain, after causing great suffering for several months, passed away, and then very gradually during the next two years the symptoms of cancer of the stomach developed themselves. The heart and great vessels were found post mortem to be entirely free from all morbid changes. But not only may the gastric branches of the pneumogastric thus influence the cardiac nerves and give rise to the special pains of neuralgic heartache; but, on the other hand, I have met with some remarkable cases which time will not allow me to detail, in which aortic disease has been associated with abdominal pain in the hepatic region of a neuralgic character, and in its mode of onset and conditions of relief behaving just like angina pectoris. Nor is it only the sensory fibres that thus vicariously suffer. A lady, fifty years of age, has been for three years under my observation with no other signs of organic disease than a weak heart and feeble pulse. This lady is reduced to a most sedentary mode of living by the fact that if she tries to walk but a few yards she is suddenly attacked with vomiting. Heberden, in his description of angina pectoris, mentions that some of his patients, who persevered in walking in spite of their pain, were attacked with vomiting. In this lady the vomiting appears without the preceding pain, the onset of gastric disturbance without previous nausea is as sudden and surprising to her as is the pain which seizes the chest in angina.

The largeness of the subject I chose when the College honoured me with an invitation to deliver these Lectures was not so broadly apparent to me as it is now that I have to take leave of it with so deeply felt a sense of the imperfection of the treatment it has received at my hands. I can only hope that the few points I have brought before you may contribute a little towards maintaining for the hour that interest which continuously belongs to everything affecting the brain.

In my first lecture, that part of it which spoke of the cornu of the fourth ventricle, I adduced Dr. Guy's observations as in support of the suggestion I made with respect to the function of the choroid plexus in the cornu. I inadvertently reversed the bearing of a part of his results, and they were thus made to appear more favourable to my suggestion than they really are. I did not say that the choroid plexuses of the fourth ventricle are overlooked in our anatomical works, but that the occupation of the cornu by the choroid plexus is not mentioned.

Gulstonian Lectures

ON

ANÆMIA.

Delivered before the Royal College of Physicians,

BY SIDNEY COUPLAND, M.D., F.R.C.P.,

PHYSICIAN TO THE MIDDLESEX HOSPITAL.

LECTURE III.—PART II.

Fatty Degeneration: The most important Result of Anæmia—of Heart—of other Muscles—of Vessels—of Viscera—Liability to Hæmorrhages explained by Vascular Deterioration.—Treatment of Anæmia: Hygienic—Dietetic—Medicinal—Transfusion.

THE frequency with which fatty metamorphosis of the tissues and an anæmic state of the blood are associated is such that the connexion between the two must be an intimate one. Whenever a tissue is deprived of nutriment it undergoes this change, its albuminous particles becoming converted into fatty granules and oil-globules. It is the simplest instance of retrograde metamorphosis of the tissues, and occurs as a physiological event in their natural decay. Pathologically, although no tissue is exempt from this form of degeneration, the muscles are particularly prone to it, and this proneness is no doubt due to the muscles being so actively employed in the metabolic processes of the body. Deprived of their due supply of oxygen, their protoplasmic elements are unable to go through their normal changes, and, instead of complex stable products, they break up into fatty molecules. Such a conversion may be effected with remarkable rapidity, witness the widespread metamorphosis in acute poisoning by phosphorus, which may be established within a day or two,[1] and in such case I believe the change is effected by the deprivation of oxygen, and the disturbance to the normal tissue metamorphosis thereby established. More often there is reason to believe that the process is of slower duration, but important as it is to determine this question, I do not think it possible to do so yet. There may be links still wanting in the chain of knowledge, but it is to my mind one of the most reasonable facts in pathology that whenever the blood is impoverished the tissues must suffer degeneration, and it is important not to disregard the fact in the treatment of anæmia. The muscle of the heart—which of all muscles requires a constant and definite supply of oxygen for its renewal, its unceasing action denoting continual metamorphosis—is particularly liable to suffer. Nourished probably in two ways, by the blood circulating through its cavities and by the arterial supply to its walls, is there not reason enough why this muscular organ should be especially singled out to undergo this metamorphosis when the blood is deficient in oxygen-bearing elements? Hence it is that the occurrence of true fatty degeneration of the heart is recognised as the most constant and most striking effect of a grave and prolonged anæmia. Out of seventy-six cases of fatal idiopathic anæmia where post-mortem examinations were made, in sixty-four it is expressly stated that the heart was thus degenerate, sometimes extremely so; in six other cases no mention is made of its condition, and in only six is it said to have been healthy. This degeneration of the heart is, in fact, as I pointed out in my last lecture, the only constant anatomical feature of cases of idiopathic pernicious anæmia. It was originally pointed out by Addison, and the observation was abundantly confirmed by Wilks, and its occurrence has been noted, as above seen, with few exceptions in every case of fatal anæmia since attention was drawn to it. Wagner, in his treatise on Fatty Degeneration of the Heart, attributes some cases to anæmia, and Ponfick described in detail the "anæmic form" of fatty heart. There is, then, general concurrence of opinion upon the association, and it is probable that it has wider bearings than we generally admit. The recognition of this sequence as a pathological fact may possibly in time throw light upon cases of cardiac degeneration at present thought to be idiopathic—cases, that is, which do not arise secondarily to inflammation of the pericardium and myocardium, from disease of the coronary arteries, from alcoholism or from fever, or, as a final event, in long-standing valvular disease. It is hardly conceivable that an impoverished state of blood should follow upon an enfeebled fatty heart; at any rate, such an impoverishment as to fall under the head of anæmia. It is far more probable that the degeneration is the result of the blood change rather than the cause of it. There are many cases where the degenerative powers have been apparently of rapid evolution, cases of acute anæmia following loss of blood. As an example of this I might instance the case related in my last lecture (No. 6), where profuse and uncontrollable uterine hæmorrhage supervened in a chlorotic subject, and where the heart was found to be most extensively degenerated. Here is another case where one factor at least in the production of the degeneration was a similar loss of blood. A woman, aged forty-six, was admitted under my care into the Middlesex Hospital on Oct. 23rd, 1880, suffering from general dropsy dependent upon a dilated and degenerate heart. She had approached the climacteric, having previously passed a healthy life, but for the past five years the catamenia had been most profuse; she called it "flooding." Three months before admission the menses apparently ceased; to reappear in great excess during the past fortnight. Œdema of the legs began about one month before, followed by swelling of the belly; but prior to this she had been getting pale, and suffering from palpitation and breathlessness on exertion. She was somewhat obese, very anæmic, and the conjunctivæ were yellow-tinged. Accounting for the dropsy, there was evident dilatation of the heart, with epigastric impulse, a soft systolic apex bruit, and irregular intermittent pulsation. She suffered from œdema of the lungs, and treatment had no effect in reducing the dropsy or removing the anæmia, which even grew more intense, although no menorrhagia occurred whilst she was in the hospital. After her death, which took place on November 12th, the heart was not only overladen with fat, but its muscular walls were flabby and extremely degenerate. The kidneys were also fattily degenerated. Here, then, was a case (and it is one of a class) where the cardiac degeneration was the most pronounced feature and was the immediate cause of death, but where it seemed probably related to, if not wholly dependent upon, the menorrhagic attacks to which she had been subject. Dr. Green has recorded a striking instance of the effect of profuse menstrual loss in inducing fatty degeneration, in the eighth volume of the Clinical Society's Transactions. The case is that of an anæmic ill-nourished girl, the subject of mitral stenosis. The occurrence of menstruation, after an interval of six weeks, and the profuseness of the flux (possibly made so profuse by the presence of the mitral disease) so lowered the standard of the blood that within five days she died in a state of exhaustion. In addition to the mitral disease and an abnormally narrow aorta, the muscular tissue of the heart was found to be in an advanced state of metamorphosis, and similar regressive changes were met with in some of the voluntary muscles. Similar examples might be quoted. The degeneration of voluntary muscles observed in Dr. Green's case is very interesting, and it is probable that if such muscles were more frequently examined in anæmia they would be found occasionally affected.

---

[1] See case recorded by myself in THE LANCET, vol. ii. 1879, p. 309.

One may, without transgressing the rightful limits of pathological speculation, attribute the origin of the areas of fatty degeneration observed by Virchow in the lining membrane of the aorta in cases of chlorosis to the same cause—the impoverishment of the blood. The well-known experiments of Cohnheim bearing upon the embolic process demonstrated the fact that the integrity of the walls of the blood-vessels depends upon their being filled with a due amount of healthy blood. The tendency to capillary hæmorrhages—purpuric spots, ecchymoses beneath serous membranes, and sometimes parenchymatous hæmorrhages — in pernicious anæmia is, I believe, due in great measure to such vascular deterioration. It has not always been found, however, in such cases; but I may say that the only opportunity of which I availed myself of examining the retinal vessels in a case of this disease where there were marked hæmorrhagic foci in the retina, enabled me to distinguish clearly that the endothelial cells of the small arteries, and those of the capillary walls themselves, were studded with minute oil-globules. That such ecchymoses are due to the condition of the blood only, is far less probable than that they are caused by actual damage to the vessel-walls through which the altered blood circulates; and when there is evidence of such vascular deterioration this explanation seems to be all sufficient. This, however, like that of the condition of the voluntary muscles, is a point which calls for further investigation.

Fatty degenerations of the gastric and intestinal glands, of the liver and of the kidneys, are met with in a certain number of cases of profound and fatal anæmia; but how far and in what way, whether as results or as causes of the anæmia, it does not seem possible yet to say. Certainly not one of these organs may be so affected; they are not so often found degenerate as the heart-muscle. The gastric glands are not often examined, and their derangement is possibly a factor in the production of the anæmia; whilst the intestinal and hepatic cells are liable to undergo a physiological fatty infiltration which must not be confounded with a morbid state. In one of the cases previously related (Case 5), the liver though certainly fatty was very remarkable, the cells affected being those nearest to the centre of the lobule, and not at the periphery, as in the ordinary fatty infiltration process. Some of the most advanced cases of visceral fatty degeneration which I have seen have occurred in cancerous subjects, especially uterine cancer; which more or less rapidly progresses in ulceration, impoverishing the blood more and more as it advances. Such instances of course differ from cases of phthisis where there is pyrexia and direct respiratory disorder to aid in the production of the fatty change.

I am not, however, now concerned with the subject of fatty degeneration as a whole, but only in relation to anæmia. We have, I think, ample evidence that there is a link between the blood condition and the tissue change, and everything points to the latter being the result of the former. At the same time we must not lose sight of the other alternative to which I have above alluded, for I do not think it is absolutely capable of disproof, at any rate in every case. I refer to the view that the anæmic condition is itself dependent upon what may be called an "inertia" on the part of the tissues, whereby they do not perform what is required of them, and failing to go through their normal metamorphosis pass into the fatty regressive state. In such a case there would be less demand for oxygen, and this would react upon the supply, and fewer corpuscles and hæmoglobin would be formed. Such an hypothesis requires, however, far more than the former, which has also received support from experimentation, the effect of continued loss of blood being found to produce fatty metamorphosis.

The treatment of anæmia, apart from the removal of its cause, when this can be ascertained, may be summed up under the head of hygienic, dietetic, and medicinal measures. On the first and second of these I need hardly dwell; their importance is self-evident. The necessity for rest alternated with moderate exercise, graduated according to the severity of the anæmia, is important. Even slight exercise is irksome and harmful until the blood is sufficiently reinforced to permit of it, and absolute rest is called for at first. The influence of air and light is of as much value in aiding restoration from the anæmic condition as their deprivation is powerful in inducing this state, and such hygienic measures as bathing act by promoting tissue metabolism. A valuable contribution to the treatment of anæmia by these means has lately been made by Drs. M. P. Jacobi and White[2] in what is a scientific exposition of the effects produced by those who practise hydrotherapy. These writers relate cases, accompanied by analyses of the urine, where wet packs and massage were employed, in addition to ferruginous medication. The effect of such treatment was to cause increased elimination of urea, to improve appetite, and to procure sleep; and the explanation afforded is that the treatment, acting through the nervous system and the circulation, promoted tissue change, and increased the capacity of the tissues and the blood for oxygen, the passive exercise of the muscles aiding also, by quickening the circulation, in the removal of the products of nitrogenous waste.

In diet the indication is to allow meat in considerable quantity as soon as the digestive organs are capable of the work imposed on them; but where, as so often happens, the digestive power is at a minimum, then recourse may be had to meat essences, peptonised foods, and (as an extreme measure) nutrient enemata. There is frequently a great distaste for nitrogenous food among these subjects, many of whom owe their anæmia in large measure to their preference for a diet of non-nitrogenous materials, and it follows, therefore, that chief attention should be paid to this point, especially as the organs of digestion are more or less deranged by the anæmic state. As I have before pointed out, digestive derangements both induce and are induced by anæmia, and by dealing with them we often strike at the root of the condition, which, however, requires also measures directed specially to it. These measures comprise the administration of certain drugs, which are comprised under the term "hæmatinic." Of these I pass now to speak briefly.

---

[2] Archives of Medicine, August and October, 1880.

Of all remedies iron maintains, as it always has maintained, a pre-eminence in the treatment of anæmia. It seems to act directly upon the blood-forming viscera, and probably also upon the digestive organs—i.e., on the gastro-intestinal tract. No wholly satisfactory explanation has, I believe, been given of the mode of action of the iron in either of these directions, or of the reason why the best results in the most marked cases of chlorosis are obtained by the administration of heroic doses far in excess of what is actually required in blood formation, and much more also than is actually absorbed. Trousseau called iron as much a specific in chlorosis as mercury was in syphilis, and there was truth in the remark, although we may not know in what its specific action precisely consists. The application of methods of blood measurement enable us to estimate the rapidity with which iron hastens recovery from the anæmic condition. Sometimes it appears to act, at any rate in the first instance, by causing an increase in the number of corpuscles without a corresponding increase in the amount of hæmoglobin (Gowers, Baxter and Willcocks); but the reverse has also been noted (Hayem), and in a series of cases published by Moriez from M. Hayem's clinique the increase in hæmoglobin was marked from the first, and, of course, greater than the increase in the number of corpuscles, which was high at the commencement. Moriez gives several tables illustrative of the effects of this and other modes of treatment, using the symbols N, R, and G to represent respectively the number of the red corpuscles per cubic millimetre, their richness—i.e., the number of corpuscles in healthy blood to which they are equivalent, and their functional value or quality, G being equal to $\frac{R}{N}$. For the normal standard to be reached not only should the figures R and N be equal and of the full amount—(i.e., 5,000,000 per cubic millimetre), but they would then contain the same amount of hæmoglobin, when G of course = 1. The mean results of twelve cases thus tabulated gave before treatment (by iron) N – 4,031,745, R – 1,991,318, and G – 0·49; after treatment, N – 4,747,675, R – 3,940,000, and G – 0·83. I give the results of similar estimations in a few cases lately in the Middlesex Hospital (see Table), the most remarkable being No. 4, where the percentage of hæmoglobin was doubled within ten days. This case was treated with sulphate of iron and bicarbonate of potash, and it will be seen that although the number of corpuscles was but slightly affected, their functional value rose above the normal. Unfortunately no numeration was made on Dec. 24th, when the actual amount of hæmoglobin was much higher still, so I cannot say whether in point of number the corpuscles in this case still remained so much below the normal.

Cases of Anæmia treated by Iron and Arsenic.

No.	Date.	Number of Corpuscles.	Hæmoglobin.	Quality of Corpuscle.*	Treatment.

* Calculated by dividing the corpuscular richness by the actual number of corpuscles, the amount of hæmoglobin being the indication of the former.

Under the use of iron the corpuscles, according to Hayem, also increase in size, and the large number of hæmatoblasts which he finds in the blood of chlorotics appreciably diminishes during the treatment. These methods of blood-measurement might be applied to discriminate between the efficacy of the different salts of iron, and also to estimate the different modes in which it is administered—from the waters of a chalybeate spring to the concentrated doses in which we often give it medicinally. Indeed, as to the form and mode of the administration of iron, I can quite confirm the opinion of those who regard the sulphate as the most rapid in its effect, and who urge its administration in large doses. It is remarkable how well it can be borne, and for my own part I am content to prescribe it in almost every case of pure chlorotic anæmia. At the same time we possess so many different preparations of different degrees of astringency, that there are scarcely any cases in which some form of this metal is not tolerated.

Next to iron, and in some forms of anæmia to be preferred to it, is *arsenic*. This metal is a powerful hæmatinic. It acts on the tissues as well as on the blood and blood-forming organs; and its effect upon the cutaneous epithelium has been actually demonstrated. It is almost the only drug which has been successful in the treatment of severe idiopathic anæmia—which more often resists all medication. The patient under Dr. Cayley's care, where the anæmia was most profound and the corpuscles had fallen to a little less than one-half the normal, notably improved under arseniate of iron. A case was recently recorded from St. Mary's Hospital under the care of Dr. Broadbent,[3] which is a good illustration of the efficacy of arsenic. A woman, forty-two years of age, who had been progressively anæmic for about four months, and was in an extreme condition when admitted (estimated number of corpuscles two days later being 560,000 per cubic millimetre, or 11·2 per cent.), was placed upon liquor arsenicalis with digitalis. The dose of the liquor was increased from two to four minims, and was administered six times daily. In two months time the number of corpuscles had increased to 64 per cent. In the remarks appended to the report of the case it is held "that there can be little doubt that it was one of essential or pernicious anæmia; the patient had the appearance characteristic of this disease, and the sub-febrile temperature; while the red corpuscles of the blood were not only reduced in number to an unusual degree, but deformed. Whether this diagnosis be accepted or not, the failure of iron to do good, and the rapid improvement during the administration of arsenic, are remarkable. In little more than two months the patient passed from extreme anæmia to apparently perfect health, with wonderfully good colour of the cheeks and mucous membranes, and she continued well and strong for some months after leaving the hospital, up to the time when she ceased to present herself for examination." Such cases as this speak strongly in favour of the value of arsenic. I have sometimes prescribed it in simple anæmia (see Table, Nos. 5 and 6) with good result, but as a rule one prefers the use of iron, which acts more promptly and fully. Phosphorus has been sometimes administered with success in essential anæmia; as, for example, by Dr. Broadbent in a case where iron had failed; but it has on the whole but few, if any, advantages over arsenic, and its long-continued administration is to be deprecated.

It was at one time thought that manganese could replace iron as a hæmatinic, when that metal had failed to influence anæmia; but it never gained much favour, and has fallen into disrepute. Indeed, from some recent observations of M. Hayem referred to by Moriez, manganese would appear to have no influence in increasing either the red corpuscles or the hæmoglobin, at any rate in the right direction. Its administration appeared to diminish the effect of iron, which was given subsequently. Another treatment that has been sometimes prescribed is that of inhalations of oxygen. The same observers have studied the effects of this treatment also, and declare that although it increases the appetite and the power of assimilation, it has no influence in increasing the richness of the blood in hæmoglobin (Moriez). Lastly, quinine and strychnine, although not hæmatinics in the trict sense of the word, are very valuable as adjuvants, and the same may be said of the mineral acids and bitters.

---

[3] Brit. Med. Journal, Sept. 25th, 1880, p. 508.

The subject of *transfusion* of blood is one which demands the most thorough examination in reference to the treatment of anæmia. In some forms of symptomatic anæmia, especially where the cause is a sudden and excessive loss of blood, there can be no question either as to the propriety of transfusion or its efficacy in saving life. It is another matter, however, when we have to deal with the insidious and progressive anæmia, which has been denoted by the term "pernicious." Transfusion has not yet been employed to a very large extent in such cases, and it has often failed of success. I find that it was performed in 20 out of 110 cases, to which I referred in my last lecture, and that the six recoveries (one of which was not permanent) all occurred in Quincke's practice. I think his success in these cases may be attributed to his having resorted to transfusion at a less advanced stage of the disease than is usually the case. His first cases were invariably fatal, and in his commentary upon them he pointed out the inutility of deferring transfusion until the heart is already advanced in degeneration, and restoration is well nigh hopeless. In one of his papers, where he summarises the results of five such transfusions, he says that defibrinated human blood was used, and from 80 to 100 cubic centimetres injected into the radial artery. (Professor Schäfer, in his valuable report to the Obstetrical Society of last year, advocates immediate injection from artery to artery as far preferable to intravenous injection, whether mediate or immediate. It will be seen that Quincke performs an operation the same as regards the recipient of the blood; but he uses defibrinated blood, and does not practise the immediate transference.) Usually, during the transfusion, the face became flushed, the pulse slowed, and sometimes very weak, almost a state of collapse occurring. In three cases a rigor, followed by fever, occurred a short time after the operation. On two occasions the transfusion was followed by hæmatinuria and casts in the urine, but not by the escape of actual blood-corpuscles. In one of these cases the amount of hæmoglobin passing off by the urine was estimated at $\frac{1}{16}$th of that injected, and Quincke points out that similar effects follow, according to Ponfick, the transfusion of an animal with blood from another of different species. In some cases petechial and other hæmorrhages follow transfusion. Quincke seems to be firmly of the opinion that by transfusion the blood is reinforced with functionally active elements, and the results of his cases apparently bear out that opinion. Transfusion, then, is a correct and rational procedure, and one which we are bound to adopt in these cases of progressive idiopathic anæmia if no ordinary treatment makes any impression on them. But its results can never be expected to be crowned with such success as in cases of acute anæmia following hæmorrhage, for the simple reason that we are dealing with a disease the origin of which lies deep in the organism, and the effects of which are already manifest in grave degenerative changes in the heart. Perhaps the less heroic measure of administering enemata of defibrinated ox blood, which was advocated by the Therapeutical Society of New York as of great value in conditions of exhaustion and anæmia, may be found of service. At any rate, it deserves the careful trial which Dr. Sansom in this country has claimed for it.

It only remains for me to thank you for the kind attention you have given me during this imperfect attempt to illustrate the leading features of anæmia. I have consciously left many points untouched, whilst many of which I have spoken are capable of much fuller analysis than I have attempted. For all the shortcomings of what has been little more than an abstract of the present state of knowledge on this subject I ask your indulgence.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES. Mr. Henry Rogers, late of Leadenhall-street, bequeathed £500 each to the South Staffordshire General Hospital and the Wolverhampton Dispensary; and £500 more at the death of his widow. Mr. Samuel Courtauld bequeathed £2000 to the Essex and Colchester Hospital. By the will of Mrs. Elizabeth Baily, late of Clifton, the Bristol Royal Infirmary and the Bristol General Hospital have received £500 each, and the Redland Dispensary and the Hospital for Sick Children, £100 each.

THE annual dinner of the Pharmaceutical Society of Great Britain is announced to be held at Willis's Rooms on the 17th of May.

ON WOUNDS OF THE KNEE-JOINT.

By WALTER RIVINGTON, F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL

(Concluded from p. 653.)

I WILL now give my own experience during the ten years of my service as one of the senior surgeons of the London Hospital. In December, 1872, a man, fifty-two years of age, was admitted into Bowley ward with a lacerated wound on the outer side of his thigh communicating with the knee-joint. It was a very severe case, for the wheel of a waggon, drawn by four horses and containing two and a half tons of potatoes, had gone over his limb, contusing the muscles and soft structures of the thigh, and blood had been effused freely into the intermuscular planes of connective tissue. Acting in consultation with Mr. Tay I sealed the wound with lint and collodion. Great swelling of the joint, leg, and thigh, inflammation, and suppuration ensued; profound constitutional disturbance, ushered in with chills and shivering; temperature rising within forty-eight hours to 105°, pulse to 144, and respiration to 33; extreme restlessness, necessitating repeated hypodermic injections of morphia; delirium, and death within a week. This was the progress and termination of the case. I am far from saying that in so severe an injury the issue would have been different if the carbolic spray had played upon the wound, and if the wound and the joint had been freely syringed out with a solution of carbolic acid, for it is not always possible to antisepticise severe and irregular wounds communicating with the intermuscular spaces, and I was informed at Edinburgh that the effect of syringing out freely the wounds accompanying compound fractures appeared in some instances to be to drive the germs inwards instead of outwards, and had not been attended with results uniformly satisfactory. I have now in the hospital a young woman with a compound dislocation of the elbow-joint, the radius and ulna having been displaced backwards with free laceration of ligaments and great bruising of the limb. Notwithstanding our best exertions, the carbolic injections were unsuccessful, the discharges became putrefactive, and the gauze dressings had to be abandoned. Nevertheless, I feel convinced that if the patient with the lacerated knee-joint could have been saved, he could only have been saved by the free use of carbolic acid and antiseptic dressings. Mr. Tay and I discussed the propriety of adopting the carbolic-acid treatment. Unfortunately that treatment had not then taken a firm root in London, and we were both sceptical concerning its alleged virtues, and inclined to believe that a strong irritant like carbolic acid was not an advisable application to delicate membranes, serous or synovial. A case had recently occurred in the hospital, and had been reported in one of the journals, in which the knee-joint was said to have been wounded, and syringed out successfully with carbolic acid, but the house-surgeon who treated the case was by no means certain that the joint had been entered either by the wound or the carbolic acid, and he remained in doubt when I had last the opportunity of seeing him. These considerations led us to reject the Listerian system. Cases have occurred in which the patella has been fractured, and considerable effusion of blood has taken place over the fracture, obscuring the injured bone. Inflammation has set in, and a fluctuating swelling, accompanied by redness, pain, and increased heat, has presented itself to the surgeon beneath the skin and superficial fascia, and apparently over the patella. Believing that he had to deal with an abscess, the unwary practitioner, be he general practitioner, surgeon, or house-surgeon, has taken a scalpel or lancet, and made an incision, letting out nothing but blood. With the emission of the blood the swelling has subsided, and to his mortification the practitioner has discovered the transverse fracture of the patella, and becomes painfully alive to the fact that he has opened the knee-joint.

Two such cases came under my observation some years ago, and what was the issue? In both severe inflammation and suppuration, calling for free incisions into the joint and limb and insertion of drainage-tubes; in both a serious illness, in one instance terminating fatally, in the other more fortunately in recovery with a stiffened limb. Similar catastrophes have followed interference with bursæ communicating with joints. Can we doubt with our present experience that the fluctuating swellings over the fractured patellæ might have been opened safely under the protection of the carbolic spray? And as to bursæ, I have now in the hospital a case of ganglion communicating with the knee-joint which I dealt with successfully by removing a portion of the wall of the sac under complete antiseptic precautions.

A case of compound fracture of the patella occurring in my practice nine years ago, in which an attempt was made to save the limb without the use of carbolic acid, terminated fatally from pyæmia. Malgaigne's hooks used for the treatment of fracture of the patella have been known to penetrate the knee-joint. One authentic case at the hospital has been communicated to me, resulting in the amputation of the patient's limb. There is a loose cartilage in the knee-joint. The septic surgeon adopting the best precautions known to him, makes the lauded subcutaneous incision of the capsule and synovial membrane, and squeezes the cartilage beneath the common integuments. Violent inflammation, rigors, pyæmia, and death are the results. Here again the operation might have been performed with perfect safety if Lister's method had been used. A young man, eighteen years of age, came under my care in February, 1875. Five weeks before admission he had injured his knee with a chisel. The wound healed and he went to work. He struck the cicatrised wound and it broke out again. On admission into the hospital there was a small tortuous wound at the lower and outer part of the left thigh above the patella. There was a good deal of pain as well as some swelling of the joint. I could not ascertain to my satisfaction that the wound communicated with the knee-joint, and I treated the case for a few weeks with rest on a McIntyre's splint, evaporating lotions, and ice. Shortly it became evident that the joint was implicated and contained pus. The patient suffered from hectic fever, his appetite failed, and he passed restless nights. He had not had any rigors since his admission into the hospital. It became evident that something further must be done. Three courses were open. 1. To make free incisions into the joint, insert drainage-tubes, and wash out the cavity daily. 2. To amputate the limb. 3. To excise the knee-joint. Looking to the condition of the patient I was myself inclined to amputate. A consultation was held, and as my colleague, Mr. Hutchinson, thought that the limb might be saved by excision, and that excision was preferable to amputation, I adopted his suggestion. The synovial membrane was found generally inflamed, and passing into a state of pulpy degeneration; there was an abscess deep in the popliteal space. The patient did well for a couple of days, when part of the flap sloughed, abscesses formed at the lower part of the thigh, and amputation was performed. Two days later pyæmia set in, with rigors and distension of the right knee-joint with pus. The aspirator was used on two or three occasions to empty the joint. Death took place three weeks after the excision, and pyæmic abscesses were found in the lungs. The case corroborates the conclusion at which surgeons not practising Lister's system have gradually arrived that excision is not a favourable mode of treatment for a suppurating knee-joint. Nor has amputation been much more successful. Preference is given to free incisions, but uniformly good results by these means cannot be expected. The case also leads us to inquire what would have been the result if Lister's plan had been applied when the joint was first wounded with the chisel?

It was with an experience of the kind just related that, at the Edinburgh meeting of the British Medical Association, I saw Professor Lister in an obstinate case of hydrops articuli incise and explore the knee-joint under the carbolic spray, with the most perfect confidence that he was not exposing the patient to any risk of life or limb. The favourable progress of the case subsequently I found to be but a type of what occurred in other cases under the like conditions. The demonstrations of Professor Lister at Edinburgh, acting I trust upon a candid mind open to the reception of truth, convinced me at once that it would be no longer justifiable, at least in regard to wounds of joints, to adhere to the old unreliable lines of treatment. Since then the advent of Professor Lister to the metropolis has rendered us all familiar with what may be accomplished safely under the protection of the spray and gauze. For a surgeon deliberately to convert a simple fracture of the patella into a compound fracture would assuredly have been deemed by surgeons of the old school as a procedure almost criminal. Nevertheless, Professor Lister and his disciples have shown that an ununited fracture of the patella may be treated advantageously by exposing the separated fragments, and wiring them together. Whether this practice should be imitated, exposed as patients would be to some accidental incompleteness or failure in the antiseptic details, is another question. For my purpose here it suffices to know that under complete antiseptic precautions a free opening of the knee-joint appears to be attended with as little risk as the division of a tendon.

With these facts before us can we doubt that Lister has established the claim which he has advanced, that he has introduced a new principle into surgery? If this be so it cannot be wrong to attribute the successful issue of the case which I related at the commencement of this paper to the application of the antiseptic treatment. But, if any further corroboration were needed, it would be found in two cases of compound fracture communicating with the knee-joint which occurred a few weeks ago at the London Hospital in the practice of my colleague Mr. Couper, who from the first has been a warm adherent to Lister's system. Mr. Couper has kindly given me permission to refer to them. On Oct. 3rd two young men of nineteen years of age were riding in a dog-cart. The horse became restive, and kicking out vigorously struck with his hoofs the left knee of each of the occupants of the dog-cart, inflicting on one a compound transverse fracture of the patella, and on the other a compound fracture of the internal condyle of the femur, the wound communicating with the knee-joint. After their admission into the Hospital Mr. Neatby (Mr. Couper's house-surgeon) injected the joints with a solution of carbolic acid (one in nineteen), carefully cleansing the wounds, and removing from the case of compound fracture of the femur a small fragment of loose bone. Drainage-tubes were inserted, and the wounds dressed with the protective and gauze. The progress of both cases has been most satisfactory. In the case of compound fracture of the patella there has been no suppuration at all, nothing but the exudation of some reddish serum. The wound has closed, and the fragments are in apposition, but not as yet firmly united. The temperature rose on the second day to 101·4°, and on the 7th to 100·8°; otherwise it has been little above the normal. In the other case some bagging of pus took place in the thigh, the abscess being opened by the house-surgeon on the fifth day. The highest point marked by the thermometer has been 102°. In both cases there has been a remarkable freedom from complications and constitutional disturbance. It is too early to predicate the ultimate issue as regards the mobility of the articulations.

Here, then, are three consecutive cases of wounds of healthy knee-joints, all of a severe character, and treated in a hospital with an established reputation for pyæmia, recovering perfectly without any of those serious sequelæ so familiar to surgeons of the last generation, and to some of the present, as to produce a profound dread of accidental or intentional wounds opening into the cavity of the articulation. And these results have been demonstrated by Lister's justifiable surgical procedures to be the rule and not the exception, when the details of his method are faithfully carried out under the immediate superintendence of the surgeon. It follows that such results would alone be sufficient to establish the immense value of the system which Professor Lister has perfected with the "prolonged patience" which has been regarded as the essence of genius. Slowly as scientific truth is received, and Syme, I believe, used to aver that after a truth had been established in Edinburgh it was ten years before it reached London, we have advanced thus far at any rate, that it is no longer a question whether Lister's system is to be accepted or not, for surgeons generally accept it in whole or in part, and gratefully acknowledge the debt which they owe to the founder. The question which now remains to be debated is the relative value of Professor Lister's system and other methods of treating wounds in particular classes of cases.[1] For joints I can imagine nothing that can be greatly superior to Listerism, but how far it may be superior in amputations, in ligature of arteries, in compound fractures, in wounds of the peritoneum (accidental or surgical), has not been finally determined. All these must be debated upon their own merits, and even if it should be proved that other treatment is as good or superior in any, or in all, for there is no finality in surgery, the decision could not detract aught from the grand results achieved by the antiseptic system in the diminution of the mortality in hospitals after injuries and operations, or lessen by one iota the obligations which surgery owes to Lister by extending its power for good, by introducing precision and certainty in place of doubt and chance, and lessening the anxiety felt by all who have serious and responsible cases committed to their care.

---

[1] Some excellent results have been obtained in compound fractures of the patella by Mr. Jessett of Erith, and Mr. Corner of Poplar, by the use of carbolic oil as a dressing after washing out the joint with a solution of carbolic acid. For Mr. Jessett's case see THE LANCET, 1873, vol. ii., p. 663.

Finsbury-square.

THE DIAGNOSIS AND TREATMENT OF WHOOPING-COUGH.

By ROBERT LEE, M.A., M.D., F.R.C.P.,
SENIOR ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

The history of whooping-cough, or chin-cough, would almost lead to the belief that the disease must have existed long before it was recognised as a specific malady and designated by a special name.

I do not propose to enter fully into the historical narrative, but there are two or three facts which I shall briefly state, the explanation of which is worthy of consideration.

In the year 1678, or about two hundred years from now, there was a mortality in London of 20,471, amongst which one case of whooping-cough and two cases of chin-cough are mentioned, this being the first entry in the returns. For fifty years after chin-cough and whooping-cough were registered separately, as though they were different in their nature, till in 1730 they were entered together, when the mortality was 152 in 27,000, or 1 death in 177. Gradually the mortality increased, till it reached an average of 1 in 29 for London; and during the last few years the whole country has suffered, and now there is a higher mortality in the total of deaths in Great Britain than has ever been registered before. Are we to explain these facts by supposing that the disease has actually increased, or that we have been slow to recognise it? I shall say no more in detail on this point, except that it is a far more important one than might be imagined, and has a distinctly practical bearing on the questions of diagnosis and treatment.

It is now about nine years ago since I began to observe, with the opportunities afforded by the practice of a large children's hospital, the various features of whooping-cough, noting any facts which appeared to be important, as they occurred from time to time. It is probable that those who have been occupied in similar practice will agree with me that among the poorer classes of a large city the average of whooping-cough cases may be estimated at nearly 10 per cent. of all cases under treatment.

The first point which forces itself on the attention is, that whooping-cough is far more prevalent in infancy than is generally supposed. Sir Thomas Watson's opinion that the disease is rare in very early life is certainly not confirmed by my experience; and as this opinion has been evidently received and restated in works on medicine—as, for example, in one of the most recent and popular in use in America, which says that the disease rarely affects children before weaning—it is well to direct attention to a possible source of error in diagnosis. I am quite satisfied that if an infant of only a few days old be in the same apartment with another child suffering from whooping-cough, whether it be weaned or not, it will, in all probability, take the disease; at least, its age will not protect it. And just as the mortality is greater among children from whooping-cough before the age of twelve months than later, so the occurrence of the disease is more general.

The next point of interest is the degree to which whooping-cough is infectious. Of late the possibility has been discussed of the principle of imitation being involved in the symptoms, and there has been a tendency to refer them to nervous derangements, much in the same way that the disease found its place in the nosology of Cullen, along with asthma, in the class of spasmodic diseases. But when it is clearly shown that whooping-cough is very infectious, and that it must be regarded properly to belong to the class of which scarlatina and measles are typical members, I need hardly remark on the little practical use of discussing how far a child may control the cough by effort, or what is the precise physiological explanation of the nervous symptoms. It will be time for that when we have ascertained how to prevent the spread of the malady and have diminished its mortality.

The following are a few cases out of a large number of which I made notes at the time that the subject of the infectious character of the disease was under investigation, and here I may remark that every precaution is taken to separate the whooping-cough cases from others.

In 1876 a child aged eighteen months was brought, on May 11th, to be treated for convulsions, being otherwise well. On July 3rd whooping-cough was clearly diagnosed—that is, fifty-three days later.

On May 22nd a child was brought with enlarged cervical glands. On June 12th the first symptoms of whooping-cough showed themselves. On July 10th a brother of the child, not attending the hospital, had the disease.

A child (male, aged ten weeks) was brought to the hospital with eczema of the head and body on May 29th. Had whooping-cough on July 10th. Another member of the same family was brought with it. A boy, aged thirty-seven months, was brought in for congestion of the brain on June 15th. On July 20th the disease was well-marked. A child (male, aged seven weeks), emaciated from ill-feeding, was brought in on May 11th. On June 19th the disease first showed itself. The mother would not allow that it had whooping-cough till four weeks after this. Another child was brought for rickets on May 22nd, and on July 14th the disease was well-marked.

In my note-book for 1878 there are the following instances: A child (female, aged four weeks) was brought with congenital syphilis on May 30th; the disease was well-marked on June 20th. Another on the same day with eczema, and after the same period showed symptoms of the disease. Another child (nine months old) was brought with eczema on Oct. 19th, and on Nov. 24th there was well-marked whooping-cough. Another child (aged three weeks) was brought with obstinate constipation on Nov. 3rd, and on Nov. 20th symptoms of whooping-cough first showed themselves. There are eleven more cases, of the respective ages of eighteen months, fourteen months, three months, six weeks, three months, eight months, seven months, four months, thirteen months, thirteen months, and eighteen months, none showing any symptoms of the disease when they were first brought, and suffering from rickets, eczema, improper food, or other causes of illness.

Taking an average from these twenty-one cases we have thirty-two days as the period which may elapse between exposure to infection and well-marked symptoms of the malady. Very frequently I have noted in cases the first symptoms of whooping-cough from a week to a fortnight before the mother would admit the fact, and in stating the average at thirty-two days I should deduct ten days or more for the obscure symptoms of the early stage of the malady, thus making the period of incubation generally three weeks.

It is singular to notice how obstinate most women are in denying that their children have whooping-cough, so that their evidence or opinion is of little value. Among these cases there was one of a mother who caught the disease. She lost her infant and had two other children ill with it. In another family two others at home caught it, one an infant five weeks old. In another the infant caught it, aged seven months.

Without dwelling long on the law of infection as regards adults, to judge from seven cases in hospital practice, and an equal number in private life, in which the father, mother, or nurse caught whooping-cough a second time, I think we may conclude that close and constant exposure to the influence of infection is the almost invariable cause of such an occurrence.

(To be concluded.)

Society for Relief of Widows and Orphans of Medical Men.—The Directors of this Society held their usual quarterly meeting on Wednesday, April 13th, at 5 P.M. Dr. Pitman, V.P., was in the chair. Applications for relief were read from fifty-nine widows, fourteen orphans, and four recipients of grants from the Copeland Fund. A sum of £1250 was recommended to be distributed at the next quarterly court, should the visitors report favourably on the cases. There were no fresh candidates for membership or for relief. The death of one member was reported. It was resolved to advertise once a quarter in the medical journals with the desire of making the Society better known. Dr. Temple, Dr. Self, Dr. Cumberbatch, Dr. Augustus Brown, Mr. Spencer Watson, and Mr. Vasey were the members selected to fill the annual vacancies in the directorship. The annual general meeting is to be held on May 18th, at 5 P.M.

ON TRICUSPID STENOSIS.

BY BEDFORD FENWICK, M.D.

(Continued from p. 656.)

THE collated cases are summarised in the table already published (No. 1), and I will discuss the subject in the order there followed :—1. Sex. 2. Age. 3. Previous History. 4. Diagnosis, Prognosis, and Treatment. 5. Size of the Tricuspid Orifice. 6. Size of the Mitral Orifice. 7. Concurrent Cardiac Changes.

1. *Sex.*—Out of these 46 cases, *41, or 89·1 per cent., were females, and only 5, or 10·9 per cent., were males.* This appears to me to be very significant, interesting, and conclusive—significant of some great and hitherto undiscovered cause, interesting as a curious statistical fact, and conclusive as a proof that tricuspid stenosis is *not* of congenital origin; for it will not, I think, be asserted that the female is more subject than the male to cardiac changes. In the ten years from 1871 to 1880 there were 31 cases of all kinds of congenital malformation of the heart exhibited, and tested therefore, before the Pathological Society. Of these, 17, or 54·8 per cent., belonged to males, and only 14, or 45·2 per cent., to females. Dr. Peacock[1] writes: "Malformations are certainly *most common in males.* Of 91 cases, 52 were males and 39 females, or 57·2 and 42·8 per cent. respectively." Nor I think would the assertion be correct of adults. Of 157 cases of all forms of heart disease treated in the London Hospital in one year, 88 were males and only 69 were females, or almost exactly 4 men to every 3 women. Finally, these 46 cases can in no sense be called "selected." They are collected from very varied sources, recorded by numerous observers, and extend over a period of fifty-five years. They are all that are noticed in Schmidt's or Virchow's Yearbooks since the early part of this century.

I may add that Dr. Norman Moore has had the great kindness to search the post-mortem register of St. Bartholomew's Hospital, and has found 13 cases there recorded. Of these, 12 were women, and only 1 a man.[2]

2. *Age.*—The youngest age at death in women was seventeen, in men twenty-one. The oldest age at death in women was fifty-eight, in men sixty-four. The average length of life in women was thirty-one years, in men 36·4 years. The majority of cases died between twenty and forty, and a rather larger number in the first than in the second decade. Only two cases lived beyond the age of fifty, and only three died before the age of twenty. This will be more clear on reference to Table II. Dr. Peacock[3] exhibited a specimen of congenital stenosis of the tricuspid from a child who only lived seven months.

3. *Previous history.*—From its birth this child was livid, and it became almost black when coughing, and it suffered much. In only one case of these forty-six is it noted (No. 18) that the patient suffered from "darkness of the surface" from birth. A few others are noted as "always delicate," "stunted in growth," and so on; but surely it will not be asserted that every delicate girl—that every badly-developed woman necessarily suffers from some congenital cardiac defect. And unless this assertion be made it seems to me most illogical to infer that this delicacy, this stunted growth, must have been the sequence of latent disease in these cases. I am inclined to believe it to be the cause of the cardiac changes. In the great majority of cases it is distinctly noted that the patient's previous health had been good. Now, I suppose it will not be insinuated that tricuspid stenosis is conducive to health or long life, or that it does not produce marked results, or even that it can exist for long without these results becoming apparent. In this connexion the previous history of the second case I have here recorded becomes very important. Here a woman enjoys good health, does hard work often, for eighteen years, suffers from and shakes off an attack of acute rheumatism; some years later is found to have her heart (presumably only) slightly diseased; five years later again shows signs of mitral stenosis, and commencing disease of the aortic orifice. This latter, after another year, and another attack of acute rheumatism, is found to have progressed into a state of stenosis. Finally, in one more year, a fresh attack of articular rheumatism has exhibited fresh inflammatory power, and it is found by post-mortem examination that the tricuspid orifice is stenosed also. Is not this the history of the march of a disease? Finally, in 23 out of 46 cases, there was a well-marked antecedent history of acute or subacute rheumatism. Out of 304 cases of all kinds of heart disease, I find that there was a previous history of rheumatism in 152, or again exactly 50 per cent. It seems to me that all these facts are powerful proofs that tricuspid stenosis in adults is an acquired disease, and is therefore *not* of congenital origin.

On reference to the following table, it will be observed that 35 of the cases died before forty, and only 10 after that age; that every male case had suffered from rheumatism; that the average length of life in rheumatic cases in men was 36·4 years, and in women 30·1 years; and that the average length of life in women with no rheumatic history was 33·2 years.

TABLE II.—*Age, Sex, and Previous History.*

Ages.	No. of Cases.	Rheumatism.			No Rheumatism.			Not noted.
		M.	F.	Total.	M.	F.	Total.	
15 to 20	3	—	1	1	—	2	2	—
20 to 30	17	2	8	10	—	6	6	1
30 to 40	15	2	6	8	—	6	6	1
40 to 50	8	—	3	3	—	4	4	1
50 to 60	1	—	—	—	—	1	1	—
60 to 65	1	1	—	1	—	—	—	—
Totals ...	45*	5	18	23	—	19	19	3
Percentages ...		100·0	48·6	50·0	—	51·4	—	—

* In one case (No. 10) no age or previous history is noted.

4. *Clinical features.*—These were noted in 28 cases. Of these cyanosis or lividity was well-marked in 22; dropsy, generally extreme, in 15; dyspnœa, often orthopnœa, in 27. In most cases there was great hepatic tenderness (and enlargement), in many severe epigastric pain. In 13 cases the area of cardiac dulness is said to have been much increased laterally. As the right auricle was in every case, save one, found after death to be (often greatly) dilated, a well-marked lateral increase of the heart's space may, I think, be considered a diagnostic feature of the disease. In three cases it is stated that there was a marked undulation of the whole left anterior chest with the cardiac action. As it was remarked in many cases that the heart's impulse was very powerful, this phenomenon was probably present even more frequently than noted. In 9 cases a very marked turgescence of the jugular veins was visible. For anatomical reasons I imagine that this condition in a less degree perhaps must be present in every case of advanced stenosis. The urine was generally very scanty, and contained albumen. The temperature, when recorded, was normal or subnormal. The pulse varied so greatly that it furnished no definite conclusions. *Murmurs* were noted in 32 cases. Of these a bruit was audible at the base in 12; in 7 being purely systolic, in 2 purely diastolic, and in 3 occurring with both sounds of the heart. A presystolic bruit was audible at the point of impulse alone in 10 cases, at or about the ensiform cartilage alone in 5 cases, and at both the right and left apices in 6 cases.

A systolic murmur was noted at the point of impulse in 15 cases, at or near the lowest part of the sternum in 9 cases. Thus in 31 out of 32 cases there was an evident mitral bruit, and in 20 cases out of 32 there were murmurs which probably were caused by the tricuspid changes, and these murmurs were audible over a limited and well-defined area, which I would thus delineate. If the point of junction of the sternum and the fourth right costal cartilage be taken, and from thence one line be drawn vertically downwards, and another obliquely to the junction of the sixth left costal cartilage with its rib, a third and horizontal line from the latter point, drawn to the right, will cut the first or vertical line just below the tip of the ensiform cartilage, and complete what I would venture to call the lower tricuspid triangle, or the area within which tricuspid stenosis murmurs are chiefly audible. I use the term "lower" because a similar figure might in like manner be drawn rather above and to the right of this which would cover the area of tricuspid regurgitant murmurs. I am aware that this is not only a smaller space, but greatly diverse in position from that assigned to general tricuspid murmurs by a great authority, Professor Gairdner of Glasgow. It is also rather different and somewhat smaller than that given by a very careful clinical teacher, Dr. Hayden of Dublin, after a thoughtful review of three well-marked cases. But, with all deference to these very accurate observers, I am inclined, after a somewhat careful review of these 32 cases, to believe that the above defined area is mainly correct, especially as, after deducing the triangle from the facts, I found that its highest point lies almost exactly over the tricuspid orifice, and that it covers the course which the blood must take on being propelled downwards from this opening towards the apex of the right ventricle. With regard to the murmurs heard, the mechanism of the cardiac cycle, the analogy of tricuspid and mitral stenoses, and the fact that a presystolic murmur is pathognomonic of the latter disease, justify, I think, the assertion that the former may also, and probably does, produce a bruit heard during the cardiac pause. And this is proved by the fact that the disease has been diagnosed during life from the presence of this one sign by Dr. Hayden and Foster, and that in 11 out of 32 cases there was a well-marked harsh, presystolic bruit heard during life within the lower tricuspid triangle.

---

[1] Malformations of the Heart, p. 117.

[2] Since writing the above Dr. Peacock has been good enough to send me a paper on two cases of Tricuspid Stenosis published in Toronto some years ago. One of these was an old museum specimen, and its sex unstated. The other was from a woman. Dr. Horrocks has also still more recently brought a well-marked example of the disease (from a woman) before the Pathological Society.

[3] Pathological Society's Transactions, vol. v., p. 64.

A. Diagnosis.—The presence, however, of this murmur in this area does not necessarily mean the existence of true orificial stenosis. Professor Gairdner diagnosed tricuspid obstruction from this one physical sign in a man in 1862. Ten years afterwards the man died, and obstruction of the tricuspid was found, not from any disease of the valves, not from any change in the orifice, but from the presence of a small globular pedunculated tumour of the auricular wall, which descended into the aperture after the manner of a ball valve. Again, Dr. Ernest Sansom informs me that a patch of roughening on the pericardial surface of the right auricle may give rise to a rubbing sound audible in the lower tricuspid triangle, and simulating a presystolic murmur even to the most practised ear. To summarise then the diagnostic features of this disease, I think it may be asserted that—

1. If there be clear evidence of mitral stenosis, which exists in every case of the analogous tricuspid condition, a well-marked murmur in the lower tricuspid triangle, if it be harsh in tone, and especially if it be presystolic in time, the patient an adult female, the systemic venous circulation more embarrassed than the pulmonary, and the right auricle much dilated, there is probably stenosis of the tricuspid.

2. If the same signs be present in a man, and the murmur in the lower tricuspid triangle be very clear, or very clearly distinct from that at the apex, and plainly presystolic in time and tone, the disease is tricuspid stenosis. If the latter conditions be not well marked it is probably a case of tricuspid regurgitation.

3. If there be a distinct presystolic murmur at the apex, not much systemic venous obstruction, and *no evidence of mitral stenosis*, the bruit is caused by some congenital malformation of the tricuspid valves, or due to roughening of those valves, to the presence of some such condition as found in Professor Gairdner's case, or to a patch of pericardial roughening localised to the right auricle.

4. If the patient be a female, has suffered much from acute rheumatism, is known to have previously exhibited signs of mitral stenosis, has great dilatation of the right auricle, a feeble cardiac action and greater systemic than pulmonary venous obstruction, even though no murmur be heard at all, or only a faint systolic bruit be audible, tricuspid stenosis may be present to an extreme degree.

(To be concluded.)

DENTAL EXAMINERSHIP.—It is stated that the Committee on Examinations in Anatomy and Physiology of the Royal College of Surgeons will meet on Monday next to consider and report to the Council on the applications and nominations of "persons skilled in dental surgery."

CASE OF MYXŒDEMA.

BY HENRY A. LEDIARD, M.D., F.R.C.S.,
SURGEON TO THE CUMBERLAND INFIRMARY, LATE MEDICAL SUPERINTENDENT TO THE CENTRAL LONDON SICK ASYLUM,
CLEVELAND-STREET, W.

ELLEN D——, aged fifty-four, was admitted into the Cleveland-street Infirmary, London, on August 26th, 1879, during my absence from home. She was being treated for dropsy, and I found this note taken, that the abdomen appeared to be ascitic, but gave no fluid wave on percussion. There was no albumen in the urine, and the patient had remained neither better nor worse.

From the description Dr. Ord gave of the disease in a paper read at the Clinical Society, early in the session 1879–80, I at once came to the conclusion that the patient under my care, who was being treated for dropsy, was the subject of myxœdema. I say from his description, for I did not see the patient shown on that occasion; indeed, this is nearly the first case I have seen; one other that I can recollect occurred in Edinburgh. I did not attend the lady, but I well remember her features and manner, which are so very characteristic of the disease. I mention this case in addition to the one I am about to give, because they were both women in somewhat advanced years.

The patient states that she was born in Tipperary; her mother died at sixty (disease ?), her father died at forty of fever. There were nine children; the patient is the eldest, two only remain beside herself, the rest died under fifteen years. She had always been healthy until she "got the dropsy," nine months before, when the skin became rough and peeled off, together with weakness in the back and breathlessness on mounting stairs. She has been married and has had eleven children; six died young, and the five living are twelve, nineteen, twenty, twenty-three, and twenty-nine years respectively. Her husband was gouty. She could never write, but can read a paper. Has been a charwoman of late. It was difficult to get much history from the patient, but she did her best, so I tried her relations. Her son-in-law had known her for seven years. She was always a slow speaker, but he thinks she is slower in speech now. She is not so hasty in temper as she used to be, and her voice is deader than formerly. Another person said she had known the patient for eight years. She was always stout and slow in manner, but she looks yellower than formerly and speaks slower, and she cannot understand her so well as before. For some reason I could not induce a daughter to come and be questioned.

The case so closely resembles Dr. Ord's very graphic description that I think I need not give all the clinical features at length, but add that it was noted that the face was puffed and waxy-looking, with a delicate colouring of the cheeks, lips somewhat pouting, no expression, and when the patient smiled the eyes almost disappeared. The tongue was characteristic, being large and flabby; there was often observed an œdematous swelling of the uvula and soft palate. The patient in disposition was quiet and cheerful; certainly very slow of understanding, for to every question she always answered, "What's that, doctor?" As an example of her disposition, I remember that on one occasion a medical friend asked her to show her teeth; she said slowly, "I haven't got none, doctor," and seemed highly amused at the joke. Her chief occupation was knitting stockings, but the needles worked slowly. She took part in the ordinary work of the ward, such as helping the nurse; and I never saw her out of temper for the eight months that she was under my constant observation. She was somewhat inclined to sleep, and occasionally was found nodding in her chair.

As to the thyroid gland, the neck was too fat to enable anyone to say whether it was small, or even present. Occasionally there were glandular enlargements in the neck, below the jaw and above the clavicle, these swellings being usually preceded by well-marked rigors. Back pain was tolerably constant. The skin was always dry, harsh, and rough, not more so on the hands and arms (she had been a washerwoman) than elsewhere. The hair on scalp was plentiful, and black. In order to test the skin I experimented with pilocarpin injected hypodermically. On December 22nd a quarter of a grain was given, the next day half a grain, without result; but on the 28th one grain acted in a few moments, and she began to wipe her face. The nurse reported that the sweating was general and lasted one hour and a half, no inconvenience being complained of, the patient saying that "there was more water in her mouth."

On December 30th the note runs: "Skin unaltered by the sweating. Extensive area of ecchymosis near pin puncture in a vein." On November 12th, also, it was noted that a pin scratch on her chin had produced some subcutaneous ecchymosis in its track of unusual character.

The œdema was general, and really was not œdema proper, for it only pitted on firm and rather prolonged pressure, very differently from what is seen in ordinary dropsy. The urine was never found to contain albumen, was repeatedly examined, the quantity passed was natural, and the colour always pale; minute analysis was never gone into. The blood I began to examine with the hæmacytometer, but on my resigning my appointment this was in an unfinished state. I made repeated examinations with the ophthalmoscope, but nothing abnormal was seen; the media were exceptionally clear, and pupils well dilated with atropin or duboisin. The laryngoscope found the larynx and vocal cords quite natural. The examination of the vagina and cervix was intended but never accomplished; in one of Dr. Ord's cases the vulva, os uteri, rectum, and anus were noted as showing change. Sight, smell, taste, and hearing were not noticeably altered in any way, neither was any bloody urine observed. The hands were as Sir W. Gull has described them—swollen, broadened, and shapeless, but this may have been accidental, seeing that she was a stumpy, clumsy woman generally. The abdomen was flabby and pendulous, always looked ascitic, but no fluid was ever detected by percussion. The temperature was recorded from October 29th, 1879, to November 18th; one thermometer was used, and from then until April 27th, 1880, two were used twice daily in each armpit without a single intermission, nurse Westell taking the greatest care and interest in these observations, for which she deserves the order of St. Katherine. There was never any marked difference on the two sides, the up and down strokes corresponding nearly exactly. The average temperature was 95° and 96° F.; 97° was reached forty-one times in eight months, 98° five times, and the temperature was above normal once only, when on November 2nd it was 99°. The note taken was: "Pain and swelling in throat inside and out, and on the following day fauces œdematous." This rise may have been due to some catarrh. I regard, then, this constant subnormal temperature as very characteristic and remarkable.

During the eight months she had fits once, on Feb. 22nd. The notes run thus: "Seems dull and heavy this morning, having had two fits yesterday. She stated that previously there was pain in her heart, her sight left her, and she felt faint." There was nothing unusual observed about the size of the heart and its action. The lungs were healthy, and no increase in size was found in liver or spleen. The digestive organs acted well. She never vomited, and had always a moist clean tongue. Her diet was a plain one always, and she was easy to please in this respect. Several medicines were given by mouth, such as diuretics, but without any result, and, as far as I noticed, she was not markedly worse at the end of eight months than she was at the commencement. Her mental state I cannot give better than as described by Sir W. Gull as that of "senile placid indifference." There was no syphilitic history. I have nothing to place on record of the pathology of this disease at present, but Dr. Ord has given the results of examinations in some of his cases, which terminated in the usual manner.

The case in point was shown, as occasion permitted, to several medical men, amongst whom were Mr. Hutchinson, Dr. Barlow, and Dr. Douglas Powell, who quite agreed with me as to diagnosis.

Carlisle.

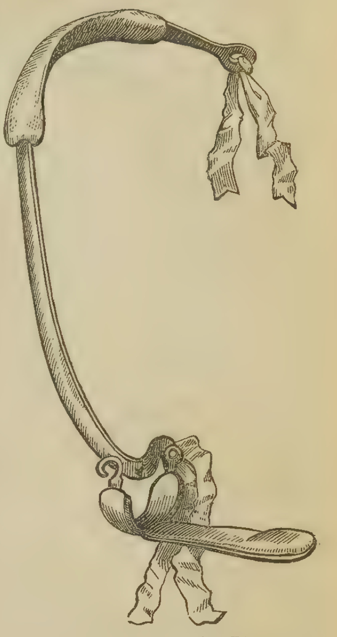
A NEW SPLINT FOR THE ARM.

BY NORMAN PORRITT, L.R.C.P. LOND.,

HOUSE-SURGEON TO THE HUDDERSFIELD INFIRMARY.

THE splint figured below consists of a flat piece of iron moulded at one extremity to fit the shoulder, and at the other to support the hand. It procures complete immobility of the elbow-joint, while possessing the following advantages over the wooden rectangular splints used for that purpose:—

The splint is not bandaged to the limb, and there is, therefore, no fear of tight bandaging and its attendant evils, circulation being in no way interfered with. There is sufficient space between the elbow and the splint to apply any dressings, antiseptic or otherwise, without removing the splint or disturbing the position of the limb. It acts as a sling by supporting the arm, and although movement of the whole arm is allowed, no movement at the elbow is possible.



In applying, the bandage is carried across the back over the opposite shoulder, round the front of the chest, again to the back, where it passes horizontally between the end of the splint and the bandage over the shoulder, once round the body, when it is tied behind. The end of the splint is thus prevented from moving outwards or upwards, and in practice it is found that the splint keeps its position. The splint is light and cheap, and can be made by an intelligent blacksmith, the length of the shoulder-piece being ten inches, of the shaft eleven inches, and the support for the hand measures six inches. If made of soft iron, the comparative lengths of the shaft and shoulder-piece can be altered by bending to suit different-sized individuals, and with a little padding for the hand and shoulder-pieces the splint is complete. Mr. A. Kempner, of Woodhouse-lane, Leeds, has very efficiently made most of the splints, and Messrs. Matthews Brothers, of Carey-street, are the London makers. It has been used by myself and others in nearly thirty cases: for example, after excision of the elbow, in cases of injury to the elbow, especially when attended with much swelling; in disease of the elbow, or where bony anchylosis is desired, and in fractures about the joint without much displacement—e. g., fracture of the head of the radius. It may be used in any case where complete immobility of the joint is desired. It is very comfortable, and patients who have worn it prefer it to others. In one case it was worn continuously for eight months, and after its use in a case of synovitis of the elbow, where the limb was bandaged to a wooden splint, an immediate improvement took place. It is not taken off at night, and when the shoulder-piece is concealed under the armhole of the waistcoat or other article of dress, it is hardly possible to see that the patient is wearing any apparatus, the hand, kept in position by a bandage carried over the wrist from side to side of the lower part of the splint, being the most prominent figure.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.

TWO CASES OF SARCOMA OF CHOROID; ONE OF TRAUMATIC HÆMORRHAGE INTO THE VITREOUS.

(Under the care of Mr. STREATFEILD.)

FOR the following notes we are indebted to Dr. Silcock, clinical assistant.

CASE 1. *Sarcoma of Choroid.* — J. B——, aged seventy, pilot, a hale old man, well preserved for his age, attended the out-patient department on Jan. 3rd, having lost the sight in his left eye. In Nov. 1880, he accidentally discovered that he could not see things on his left-hand side; since then his sight had been gradually getting worse; but he had never suffered from any pain in the affected eye. With the exception that he was "gouty," his general health was, and had always been, excellent. Vision, normal in the right, amounted only to the bare perception of light in the left eye, and was entirely lost in the outer part of the left field. By direct examination, a round, slightly nodulated mass could be seen, growing apparently from the inner ciliary region, about as large over as a pea, and yielding a yellowish-red reflex. The cornea was clear, the anterior chamber of normal depth, and the pupil active. In the lens were a few incipient striæ. The globe was nowhere tender; its tension decidedly minus. The right eye, on examination, was healthy.

On the day of admission, Jan. 31st, the left eye was excised, care being taken to divide the optic nerve as far back as possible. With the exception of an attack of gout whilst in the hospital, the patient did well, and was discharged on Feb. 2nd. Dr. Brailey, curator of the museum, found that the growth was a soft, white, vascular sarcoma growing from the inner side of the ciliary body. The cells were round or oval, many drawn out into a short tail, having one, sometimes two, large oval or round granular nuclei.

Case 2. *Sarcoma of Choroid.*—J. M——, aged sixty-nine, bootmaker, a well-nourished, healthy-looking man, was admitted on Feb. 7th. He stated that nine months previously he noticed that he could not see objects on his right-hand side. Latterly his sight had been getting rapidly worse. He had never had any pain in the affected eye. His health had always been good. On direct examination, a large mass could be seen springing from the inner ciliary region of the right eye, having much the same appearance and occupying a similar position to that described in the first case, but covering a somewhat larger area. The cornea, anterior chamber, and pupil were unaffected, a few commencing striæ being observable in the lens. The globe was not tender, its tension minus. The left eye, on examination, seemed healthy. Vision was good in the left, but almost totally lost in the right. The eye was excised, the optic nerve being "cut long," as in the previous case. The patient was discharged on Feb. 14th. Mr. Brailey reported that the growth was a sarcoma apparently starting from the choroid, but filling up half the eyeball, though not reaching to the optic disc. The cells were spindle-shaped, many tripolar, with large oval granular nuclei.

Case 3. *Hæmorrhage into the Vitreous.*—A. G——, aged twenty-six, attended as an out-patient on February 14th, having lost the sight of his right eye. Four weeks previously whilst loading a gun it exploded, blowing his right thumb off. Half an hour afterwards he found that he could not distinguish anything with his right eye. He was taken to Guildford Hospital, where he remained some time. Four or five days after the accident he could count fingers held up in the lower and outer part of the right field. He had never had any pain in the damaged eye. When tested there was total loss of vision in the upper and inner part of the right field, light objects and shadows being distinguishable in the remaining portion. On the lower eyelid, close to the outer canthus, was the recent cicatrix of a small wound; the ocular conjunctiva in this region was a little injected. The cornea, anterior chamber, iris, and lens were unaffected. With oblique illumination a bright-red reflex was obtained from the lower and inner ciliary region; no normal fundus reflex elsewhere. The vitreous anterior to the extravasation was a little cloudy. There was no tenderness of the globe, its tension slightly minus. He complained of slight photophobia and lacrymation, but of no pain.

Remarks by Mr. Streatfeild.—The three cases can only be considered in one group, inasmuch as they were attending at the Moorfields Hospital at the same time, and as they afforded an opportunity of some comparative observations to be made in practical diagnosis, which, as regards the intraocular sarcomata, is always a matter of urgency and importance, inasmuch as in such cases the eyeball must be immediately excised. In these two cases the eyes, it has been observed, were of less than the normal tension, whereas it is generally supposed that intraocular growths are accompanied by an increase of tension. This is true only of growths which have attained larger size than had either of these tumours; and that in the early stages the tension is, on the contrary, diminished may be due, as Dr. Brailey has remarked, to loss, by the growth, of some part of the secreting surface. In neither of these two cases had the tumour attained such a size as to distend the eye and cause the hardness of a later stage of the disease. Neither of the patients had had any pain, the media were clear, and the anterior chambers not shallow. By observation at first, with the naked eye, in ordinary daylight, an unusual light reflection from a part of the fundus could be seen in these cases, and much more distinctly seen, of an orange-red colour, with the concentrated light of the ophthalmoscope lens (oblique illumination). With the ophthalmoscopic mirror, looking obliquely, the tumours could be seen in profile, and retinal vessels on their convex surfaces. The retinæ were evidently detached and lifted up, but these were no ordinary detachments of the retinæ; their colour and dense opacity, their steep convexity, and the absence of any folds or creases on the surface of the elevations showed this. The ages of the patients excluded the probability of their being gliomatous growths. Nor could they be tubercular; they were too large, abrupt, and regular in shape, and, again, the patients were not young. Were they subchoroidal effusions? Excepting the consideration of their ages the same objections prevailed. What could these large, single, rounded, prominent elevations in the anterior part of the periphery of the fundus in each of these cases be but sarcomatous growths from the choroid or ciliary body? I thought they were both of the nature of sarcoma, and operated at once. The growths were not yet comparatively very large, and the optic nerves, cut across in the excisions, were healthy, so that the prognoses are good. The third of the three cases, herein reported by Dr. Silcock, seen at first by daylight with unaided vision, and without a knowledge of the history of the case, might have been also taken for an intraocular growth in that part of the fundus from which the sarcomata had their origin, a reddish glare being reflected from a part of the periphery of the vitreous chamber. But this appearance was not so exactly localised as it was in the cases of the tumours, and oblique illumination made the contrast with them greater, and the diagnosis certain. Instead of orange-red, with retinal vessels on the surface, it was uniformly of the colour of blood recently effused, partly occupying the back of the vitreous chamber, and partly in contact with the posterior lens capsule, irregular in outline instead of being rounded, and evidently concave instead of projecting forwards. It could be nothing but a blood-clot moulded to the shape of the surrounding parts. The man thought the thumb which was "blown off" struck his eye, but the correspondence of the small cicatrix of the outer part of the lower lid, and a little hard mass which could be felt in the centre of the corresponding patch of the injected ocular conjunctiva, which I took to be another scar of the same date, made me think that, not improbably, a shot had penetrated the lid, and also the sclerotic, and may be found hereafter in the eye, if it should become necessary to excise it. The tension was already deficient, the eye beginning to waste.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

CRUSHED FOOT; AMPUTATION; SALICYLIC-SILK DRESSING.

(Under the care of Mr. T. D. Ransford.)

J. G——, aged thirty-seven, admitted January 6th, had previously been a patient, under the care of Mr. Hamilton, with injury to the knee of the left leg, which resulted in a stiff knee. He was at work in the Mersey Steel and Iron Works, when a ton weight of iron fell on his ankle and crushed it to a pulp. After consultation it was determined to amputate the limb at the lower third, which was done with a long anterior and a short posterior flap, with Lister's antiseptic method, and dressed with gauze. The dressing was repeated every morning, on account of the extensive serous oozing soaking through all dressing, till some salicylic waste silk had arrived from Leeds on the morning of January 12th, when it was determined to try it, as recommended by Mr. MacGill. Temperature 100°; pulse 72. The wound looked well, the sides had been left open to allow of free drainage. One drainage-tube came away with the dressing, the other was left in. The wound was covered with the protective, and one or two layers of wet gauze were put over this, then about a quarter of a pound of the waste salicylic silk was picked out and spread over some gutta-percha, and the stump laid in it. The whole was then bandaged to the limb by gauze bandage. This dressing was kept on till January 19th, seven clear days, the temperature being about 98° to 99°, and the pulse 70 to 76. No discharge showed through anywhere, and the dressing was only changed to remove the drainage-tube. The wound was dressed in the same way again, and, as the temperature and pulse were normal, it was allowed to remain on for ten days, up to January 29th, when the dressing was removed and the whole stump was found soundly healed, with the exception of two small points on each side, less than half the size of a threepenny piece; these were dressed with lint and boracic acid lotion, and took longer to heal than might have been expected, seeing the rapid progress made with the silk dressing. Sent to the country, quite well, on February 14th.

Remarks.—Although this case was not dressed from the very first with the silk dressing, yet, as far as it goes, it bears out all that Mr. MacGill has said in its favour in THE LANCET of January 1st, page 10.

HORNY TUMOUR OF LIP.

(Under the care of Mr. T. D. RANSFORD.)

For the following notes we are indebted to Mr. Ward.

R. B——, aged fifty-seven, admitted Feb. 16th into the Albert ward. Five years before a small white blister appeared on the middle of the lower lip at the junction of the skin and mucous membrane, and remained as such for two years, after which it began to grow steadily. The patient never noticed that it grew more rapidly at one time than another. He said that there never had been any discharge from it, and that the mass had always grown from underneath. During the last two years he had suffered from indigestion and attacks of bronchitis. No history of syphilis.

On admission he was in good health, but rather delicate-looking. A large mass extended nearly at right angles from the margin of the lower lip, its base occupying about an inch of the space of the lip, and protruded about three-fourths of an inch. At its free border it was divided into two unequal parts, the break having been caused by a removal of part of the mass by the patient. There was no hardened base, but the mucous membrane on the left side of it looked white. There was no enlargement of the neighbouring glands, but the patient stated that the glands under the jaw occasionally became enlarged and painful. The mass was quite painless at the free border, the patient being able to remove pieces of it with his finger nails. On compressing the base it was very painful.

The tumour was removed on the day of admission by cutting parallel with the lip with a pair of scissors, the white-looking mucous membrane being also removed and the skin and mucous membrane were drawn together, and the wound dressed with lint and boracic acid lotion. Discharged well five days later, the 21st inst.

Remarks.—The interest of this case arose from its growing from the usual site of an epithelioma, but the long history and the absence of any infiltration of the neighbouring tissues or glands were alone enough to establish its innocent character. The tumour, with the exception of a piece reserved for the microscope, has been sent to the Royal College of Surgeons Museum, Lincoln's-inn-fields. It was an ordinary papilloma.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Cylindroma of Popliteal Space. — Cancer of Rectum. — Villous Polypus of Bladder. — Cirrhosis of Liver in a Child.—Membranous Tracheitis following Tracheotomy.

THE ordinary meeting of this Society was held on the 19th inst, Dr. Wilks, F.R.S., President, in the chair. The chief communication was by Mr. Harrison Cripps upon "cancer" of the rectum; it was admirably illustrated by a large series of microscopical specimens, drawings, and diagrams. Mr. Godlee showed in the ante-room a curious case of arrested development of all the limbs.

Mr. BUTLIN exhibited a specimen of Cylindroma. It was the primary tumour removed from the ham of a boy aged nine, who had died from recurrent sarcomatous growths, which had been brought before the Society by Mr. Cripps (see THE LANCET, p. 213). The primary growth apparently sprang from the posterior ligament of the knee-joint; there was rapid local recurrence as well as widespread secondary dissemination, tumours being connected with the ilium, one of the ribs, and occurring also in the abdomen and pelvis. The microscopical characters of the primary tumour were those of cylindroma, composed of cylindrical, polygonal, and hexagonal cells within a hyaline matrix which apparently proceeded from change in the vessel walls. This form of new growth has been described in connexion with the skull and in the submaxillary and parotid glands; it has only once been observed in lymphatic glands. It belongs to the sarcomata, and in this case the recurrent and secondary growths were typical specimens of round-celled sarcoma. Mr. Butlin attributed the peculiar shape of the cells to their mutual compression and removal of intercellular substance.

Mr. HARRISON CRIPPS exhibited a series of specimens and drawings illustrative of the development of so-called Rectal Cancer. He found them all to conform to one type, the adenoid; the different appearances in various specimens representing different stages in its growth, which assumes two main forms—viz., one where it begins between the muscular and mucous coats, and, when ulcerating, makes an ulcer with a base formed by the hypertrophied muscular coat, and spreading at the margins; the other where it forms from the first a projecting tumour, clinically innocent. The latter is usually described as a papilloma, the former as an epithelioma, but they are both probably opposite types of the same disease. Section through a well-marked slowly-growing tumour shows spaces lined by cylindrical epithelium resting on retiform tissue. In the rapidly-growing tumour the same spaces and epithelium are present, but in a less defined form, both the cells and fibrous tissue being embryonic. The mode of development of these spaces is ascertained by observing the growing margin, which exhibits epithelial buds and processes arranged in dendritic fashion. These leaflike processes bend over and coalesce, forming the spaces lined by epithelium, which at an earlier stage was on the surface. Secondary outbuds of epithelium grow in these spaces by the proliferation of the cells. He had not been able to trace a direct continuity of growth between the Lieberkühnian follicles and surface epithelium and the deeper-seated new formation, a greater or less amount of retiform and fibrous tissue intervening. But in this intermediate tissue there is, especially near the new epithelial growth, a large amount of leucocytes, and their presence has suggested the view taken of the origin of the deep-seated epithelial new formation. The rectal mucous membrane is composed of cylindrical epithelial cells on the surface of retiform tissue, the number of cells on a given area (there are about 50,000,000 to the square inch) being very large, owing to the existence of numerous depressions of the mucous membrane the Lieberkühnian crypts. Each epithelial cell may be regarded as having an individuality of its own; its nucleus is capable of division and of passage into the subjacent retiform tissue. There is no morphological distinction between the epithelial nuclei and the retiform cells, and Mr. Cripps believed he had seen in some specimens an actual transition of the former into the latter. If such a transition or migration take place, the subsequent transformation of the retiform cells into deeper-seated epithelium is feasible—the nuclei being considered as embryonic forms of the surface epithelium, which subsequently develop into adult epithelium. Dr. Moxon's observation of cancer in the liver, secondary to rectal cancer, reproducing all the structures of Lieberkühn's follicles, is explicable on this hypothesis, which requires only the transplantation of lymphoid elements originally derived from epithelium to a distal organ. The various names applied to these rectal new growths, as sarcoma, epithelioma, &c., are so far erroneous that they are only descriptive of particular parts of the growth—the nuclear or immature part, the epithelial or adult parts, &c. As to the cause of this malignant disease, it might be supposed that an obstruction of the lymphatics would cause a tumour to develop, hindering the removal of the potential epithelium, but that view does not account for the dissemination of the growth. It must be assumed that the cells in the retiform tissue cannot find their way into the lymph stream, that being fixed they develop into epithelium in the deep tissues, and give rise there to a formation reproducing the characters of gland tissue.—Mr. DORAN pointed out that the intestinal epithelium was rather shed than reabsorbed, and that it was more probable that the lymphoid cells should be the progenitors of the epithelial cells than the converse; and that, under morbid influences, they should undergo that transformation before coming to the surface. Such a view explains the origin in deep tissues of cysts well lined with epithelium. In the ovary such cysts may be derived from the epithelium of the tunica albuginea and Graafian follicles; but the ovary has the power of forming any tissue (e.g., in dermoid cysts) without any impregnation.—Dr. THIN said that Mr. Cripps, by his careful research, had done for cancer of the rectum what Thiersch had for cancer of the lip, and Waldeyer for cancer of the breast. But his valuable facts were supplemented by theories to which he (Dr. Thin) could not assent. This was the third occasion on which he had heard the doctrine put forth that connective tissue could be formed from epithelium. Dr. Saundby had applied this view to the histogeny of granular kidney and cirrhosis of the liver. It is no sufficient reply that this contradicts our knowledge of the embryonic conditions; but in neither instance can any appearance be found suggestive even of the probability that there is a formation of connective tissue from epithelium. No doubt in many specimens the nuclei were visible and not the cells which contained them; but the explanation that the epithelium sheds its nuclei is purely hypothetical, and depends upon the interpretation of the specimens given by the observer. He himself held the view that leucocytes in contact with cancerous epithelium became converted into such epithelium, and that generalisation is accounted for by the transportation of such leucocytes by means of the bloodstream to distant organs, where they give rise to new development of cancer cells.—Mr. GODLEE thought great care should be exercised before tracing a connexion between connective-tissue cells and epithelium. The term "cylindroma," employed by Mr. Butlin to a tumour which appeared to be a round-celled sarcoma, was confusing, as implying an epithelial or cancerous structure; whereas the growth in question seemed to be one of those sarcomata which have fibrous spaces like a carcinoma, but which in their recurrences in other parts have purely sarcomatous characters.—Mr. BUTLIN said he showed the specimen as an example of what had been called "cylindroma;" which is, however, a round-celled sarcoma. It had no relation with the columnar-celled epithelioma which had sometimes been spoken of under the same name. He could not admit that Mr. Cripps had done for rectal growths what Thiersch and Waldeyer had for those of the lip and breast. Waldeyer traced the origin of mammary cancer immediately from the epithelium to the ducts; and in all Thiersch's plates the surface epithelium could be seen extending downwards in direct continuity with the new growth. In neither case had there been any necessity to adopt such a theory as that given by Mr. Cripps. Dr. Thin appeared to have changed his views as to the part played by the epithelium, which a few years ago he described as not doing anything except dying out. There was one link wanting in Mr. Cripps's argument; he had not been able to show any transitional form between the nuclei and the new epithelial cells.—Dr. THIN was not aware that he had changed his views; he still held that epithelium does not beget epithelium, but that the dying cell gives out an influence which causes leucocytes to be transformed into epithelium.—Mr. R. W. PARKER asked whether Mr. Cripps really held that cancer could be developed primarily from structures which were originally formed from the mesoblastic elements of the ovum. Such a view would be contrary to the most modern doctrine which accepts as correct a purely embryological classification of all morbid growths. He (Mr. Parker) had recently examined a tumour from the humerus, which was said to be a primary one. It very closely resembled a cylindrical epithelioma of the rectum, such as those shown to-night. On making subsequent inquiries, it turned out that the patient had been ovariotomised some years previously. He was inclined, therefore, to the belief that the ovarian tumour was the primary lesion and was a cylindrical epithelioma, and that the growth in the humerus was a secondary manifestation. He was strengthened in this view by the examination of an ovarian tumour removed by Mr. Thornton, which on section was found to consist of a similar cylindrical form of growth. The questions, therefore, arose, were the present views regarding the development of the ovary correct—viz., that the ovary is formed entirely of mesoblastic elements, or must we give such a disease, when it recurs in the ovary, some other name than cancer; or must we give up the embryological doctrine of tumours, which teaches that cancer cannot occur primarily in tissues of the connective (mesoblastic) series. For his part, the embryological doctrine held good in nine-tenths of all the cases, and he believed, as our knowledge of embryology improved, that it would be found to hold good in all cases, and that it might even be possible to correct our physiological views by the aid of pathological specimens such as the one he had just alluded to.—Mr. CRIPPS, in reply, said that a gradual investment of the nuclei by protoplasm, on their way to become epithelium, could be seen in some specimens, especially in the adipose tissues. The lymphoid cells between the fat cells could be seen of increasing size, gradually displacing the latter. He felt absolutely certain of the conversion of lymphoid cells into epithelium, and he pointed out that in the liver not only do these cells develop into epithelium, but form the definite tissue of a Lieberkühnian follicle, and in that fact the view that they are direct offspring of the original cells of the rectal mucous membrane receives confirmation.

Mr. TREVES showed a specimen of Villous Polypus of the Bladder from a woman forty-eight years of age, who died of pyloric cancer, and had been subject to hæmaturia for fourteen years. The polypus was attached midway between the summit of the bladder and the urethral orifice, and had a flocculent appearance. Sir H. Thompson had made a distinction between the hæmaturia due to cancer of the bladder and that due to villous disease—viz, that in the former it is intermittent, and in the latter constant, but not profuse. However, in this case the hæmaturia was not only intermittent, but often very severe, so that large clots were passed. The hæmorrhage, when present, was also increased by the slightest movement.

Dr. SEYMOUR TAYLOR showed a specimen of Cirrhosis of the Liver from a child nine years of age, who had been under Mr. Osborn's care for a congenital hydrocele of the left side. Death took place rather suddenly. The child had been subject to epistaxis and morning sickness; it had never been jaundiced, and there was no history of syphilis or of spirit drinking. After death there was much ascites, slight œdema, no sign of intestinal hæmorrhage, and no evidence or appearance of inflammation. The liver had the characteristic hobnailed character, with general capsular thickening. The spleen was large and firm. Dr. Murchison records a case in a boy nine years of age, where there was evidence of alcoholism; and Dr. F. Taylor last year showed a specimen from a child in whom the history was negative.

Dr. CARRINGTON exhibited a recent specimen of Membranous Tracheitis, following an impacted nutshell in the larynx. Tracheotomy had been performed. The case was not exposed to the diphtheritic poison. The nutshell was lodged below the vocal cords, and its presence did not apparently give rise to the membranous inflammation which started from the tracheal wound.

The following specimens were exhibited by card:—Fracture of Spine, by Dr. Carrington; Hygroma of the Neck, by Mr. Treves; Congenital Malformation of Foot and Hand (photographs), by Dr. Mortimer Balding; Stenosis of Tricuspid and Mitral Valve, by Dr. Burnet.

CLINICAL SOCIETY OF LONDON.

Cross-legged Progression. — Excision of the Tongue.

THE ordinary meeting of this Society was held on the 22nd inst., T. Smith, Esq., Vice-President, in the chair. It was marked by a prolonged and interesting discussion upon excision of the tongue for cancer, arising out of a paper read by Mr. Stokes of Dublin.

Mr. W. J. TYSON (Folkestone) read notes of a case of Cross-legged Progression. J. W——, aged sixty-seven, a waggoner for many years, at the age of fourteen fell on a barn floor and injured the right leg. This accident kept him in bed for four months. He says from this time he could never straddle a horse, and always walked lame. Sixteen years ago he began to have difficulty in keeping up with his horses, his legs becoming more and more approximated. The last fifteen months he has walked cross-legged. This latter position is maintained day and night. With some force the legs can be unlocked and brought parallel, but not without causing pain. There is only the slightest movement in each hip-joint; the surrounding bone appears thickened. When he gets up in the morning, or when he starts to walk, a crackling noise is distinctly heard. Both extremities are extremely adducted and everted; the heels are far apart and the toes close together. The legs cross one another just above the knee-joint, the right being in front. The hip-joints are the only ones at all affected in the body. Both knee-joints *can* be fully flexed, but these are scarcely moved except in sitting or lying down. He can walk with two sticks very slowly and for a short distance, but he nearly always uses two crutches. In commencing to walk, the crutches are first placed forwards, and then the body is thrown on to them; the lower part of the spine appearing to take—in fact, it really does take—the place of the hip-joints; there being hardly any movement in hip or knee on either side, the body is thus raised by the crutches and swung forwards. The absence of knee movement in progression constitutes a difference between the present case and those exhibited by Mr. Lucas, in one of which the knee movement was considerable. The following description best explains the cross-position of the limbs. In the original accident some injury to the right hip-joint occurred, and during its repair adduction of the right leg took place. This condition then would naturally account for the difficulty he had as soon as he was able to get about of sitting across a horse's back. The right hip became anchylosed, and as time went on, and the right leg became more adducted, there was a tendency for the left one to pass across to the right side in order to maintain equilibrium, and as movement in the left hip-joint became less, so anchylosis would gradually come on here, and thus, after a time, both hips would become fixed, the movements lost in these joints being supplied to a great extent by a complementary movement occurring in the lower part of the spine. The cause of the cross-position of the legs was discussed when Mr. Lucas brought forward his two original cases before this Society on Oct. 22nd of last year, but more fully by him subsequently in a paper in THE LANCET in the following December. Three theories were mentioned in Mr. Lucas's latter communication—(1) the adduction, (2) the gravitation, and (3) the optional, or when the leg on the same side of the injured hip is thrown on the limb of the opposite side for the purpose of rest and relief of pain. It seems that adduction of the limb must be the commencement of all these cases, it making no difference whether the adduction is at first produced optionally, or whether it comes on in the course of the hip-joint disease, and providing that the limb is sufficiently and permanently adducted so as to interfere materially with progression, the other leg will naturally be passed across its fellow to keep the body in the erect position, and also as the easiest way for walking. In the commencement of these cases there is probably the usual inversion accompanying the adduction, but as soon as the patient attempts to walk this is slowly changed into eversion, as this latter position allows greater scope for the movements of the knees and ankles.—Mr. CLEMENT LUCAS regarded these cases as little more than pathological curiosities; he had only heard of two other cases besides Mr. Tyson's since he drew attention to the subject, and he thought the condition must be very rare and invariably the result of double hip disease. He had not committed himself to any theory of its production, but agreed with Mr. Marsh that adduction was the main cause. Mr. Croft's view could not hold. He himself had thought that the position of the limbs was at first optional in order to relieve pain, and that it increased because the knees were used in progression. His cases showed that the disease might be of a different character, one of them being a man with osteo-arthritis of the hip, and the other a lad with ordinary pulpy degeneration and dislocation.—Mr. HOWARD MARSH said the condition consisted mainly in adduction and fixation of the limbs, which would not occur unless both hip-joints were diseased. Cases of progression with considerable, but not such extreme adduction, were more common; indeed, in every case of chronic hip disease there is very marked adduction, not to the extent of producing the cross-legged position, but compensated by the up-tilting of the pelvis on the affected side. He did not understand in Mr. Tyson's view how the opposite hip could become anchylosed without having been previously the seat of disease.—Mr. T. SMITH agreed with Messrs. Lucas and Marsh, because certainly there is adduction in old hip disease, and yet the cross-legged position is rare. It was difficult to see how the cross-legged progression could occur unless both hips were diseased, and if they are diseased, its non-occurrence was certainly remarkable.—Dr. WILTSHIRE inquired whether the affection might not be neurosal, and related the case of a lady who, after a slight blow on the hand, became the subject of a condition attributed to an ascending neuritis.—Mr. TYSON, in reply, said that the original accident occurred many years ago. If adduction be extreme, then the cross-legged posture must occur. The patient had only walked in this way for the past eleven months, and the peculiarity of the case was that he made no use of his knees in progression, obtaining all his movement from the lower part of the spine.

Mr. WM. STOKES (of Dublin) read a paper on Excision of the Tongue. He commenced by alluding to the change that surgical opinion has lately undergone in reference to the merits of excision of the tongue, and mentioned the views of Professor Gross and Mr. Collis on this subject. The particulars of six cases in which the writer had excised the tongue were then briefly stated, in which relief from suffering caused by enlargement of the tongue, difficulty of deglutition and articulation, discharge and pain, was obtained in all as an immediate result of the operation. In two of the cases a considerable time—twenty-two months and eighteen months—elapsed without any recurrence of the disease; in two others three months and four months elapsed; in one the patient was lost sight of immediately after the wound healed, and in only one of the cases was almost immediate return of the disease observable. Performing the operation at an early period of the development of the disease, if possible before glandular complications, was strongly advocated, and Sir J. Paget's views stated, as regards the small risk attending the operation. The question of unilateral or bilateral ablation was then discussed, and the advantages of the latter pointed out. The question of what is the safest and best method of excision was then considered, as well as the two special dangers of the operation, hæmorrhage and septic complications. The author observed that removal of the tongue by a cutting operation is not only more liable to be followed by hæmorrhage, but also by septic infection, the outcome of which latter is in a large number of cases either pulmonary gangrene or septic pneumonia. These are not observable at all to the same extent in the cases operated on by the écraseur. In proof of this, the statistics of Dr. Scheffer and Mr. Collis were considered, in the former of which it was found that the percentage of mortality from septic causes in the cases operated on by incision reached the startling figures of 60, and in those of Mr. Collis 61. Mr. Barker's cases were also alluded to, but the number of cases (3) operated on by incision, in which there were no septic consequences, was not considered sufficiently large to materially affect the conclusions arrived at. The disadvantages of certain of the écraseur operations were then pointed out, and the author concluded by describing the method of operating he preferred. He commences by transfixing the cheek at a point corresponding to the last molar of the lower jaw, and makes an incision downwards and forwards towards the angle of the mouth, terminating a few lines above it. All bleeding vessels being secured, and the parts retracted, a ligature is passed through the tip of the tongue to facilitate the drawing forwards of the organ by an assistant. This being done, a straight Liston's needle, armed with a double strand of carbolised silk, is passed through the base of the tongue at a point behind the foramen cæcum. In front of this the chain of an écraseur is passed round the tongue, and the organ gradually severed. This portion of the operation is done very slowly, taking from thirty-five to forty-five minutes. The author never witnessed in any of his cases any secondary hæmorrhage, immediate or remote. The wound in the cheek is then brought together by a few points of interrupted suture. The free ends of the strand of silk passed through the base of the tongue are then fastened temporarily, by adhesive plaster, to the side of the cheek or forehead. This double thread, which in the event of secondary hæmorrhage or traction, would be of much assistance in enabling the surgeon to draw forwards the base of the tongue and secure the bleeding vessels, is removed usually on the third or fourth day after the operation. The author believed that, by the use of the écraseur employed in the manner he described, coupled with antiseptic measures during the healing of the wound, the operation is attended with little pain, with the minimum of risk as regards either primary or secondary hæmorrhage, or those septic troubles which, after all cutting operations, are so fruitful a means of raising the mortality attending this important operation.—Mr. HEATH said that in this country the tongue was more freely operated upon than was assumed by the author. As to the question of growth, after removal, in Mr. Barwell's case there was a considerable increase; and in his own case, where more than half was removed, the stump of the tongue, nine years after, appeared to have enlarged. The mode of operating was different in different cases. He had now entirely given up the galvanic écraseur, in favour of the chain écraseur, and had never found occasion either to pierce or incise the cheek; for, by bending the écraseur and pulling forwards the tongue, the instrument could be applied far back. Whether a unilateral or bilateral operation should be performed depended on the merits of the case; and he agreed with Mr. Baker that a unilateral operation should be done when necessary; it also enabled the surgeon to examine the two halves of the organ when split in the median line.—Mr. MORRANT BAKER advocated the unilateral method when the disease was sufficiently limited. The median incision avoided the severance of arteries and rendered the detachment of the organ more easy, and it allowed of removal of the other half if the disease were found to encroach near the median line. He thought division of the cheek might be more often done with advantage, especially when the disease extended far back. It allowed also of a better control of hæmorrhage. He thought the tongue could not grow after incision, but that an apparent increase in size might result from the contraction of the cicatrix. And as to the retention of speech, it must be remembered that the tongue was not wholly removed when only the portion in front of the foramen cæcum was excised. When completely removed the mouth has a very different appearance; there is a large hollow in the place of the root of the tongue, and the arches of the palate are approximated. Mr. Gant had recently exhibited a case of nearly entire removal, which had been effected much on the plan adopted by Collis. That patient could hardly articulate. Mr. Baker had not himself found tracheotomy necessary; but in a case where he assisted, tracheotomy had to be done on account of blood flowing into the trachea. A fresh hæmorrhage occurred just before the removal of the tongue was completed, and the blood flowed more readily into the trachea than when there was no tube in it. Of course it might be said that the pharynx should have been plugged.—Mr. MACCORMAC pointed out that the trachea itself might have been plugged. He asked Mr. Stokes what measures had been taken to remove the diseased glands, which occurred in some of his cases. Permanent success depended upon this. Any modification of the operation, by splitting the cheek, &c., was justifiable if it facilitated the removal of the diseased tissues in the floor of the mouth. The difficulty of removal of infiltrated glands was considerable, and he should like to know whether the plan followed by Mr. Stokes enabled him to effect their removal. He was surprised to learn that an operation producing a crushed and bruised surface (as did the écraseur) is followed by less risk of septic processes than a simple cut wound. However, the fact remained. He had once or twice divided the tongue without any hæmorrhage of moment occurring. — Mr. BARKER said that the list he had furnished to Mr. Stokes somewhat altered the relative rate of mortality after different methods of operation. At University College Hospital, from 1871 to 1879 inclusive, there had been 51 cases of lingual epithelioma, in 34 of which excision was performed. Eleven of these cases died in consequence of the operation — 5 from septic pneumonia, 2 from septic bronchitis, 2 from septicæmia, 1 from pyæmia, and 1 from œdema of the glottis. A large proportion thus died from septic causes. Of these cases 25 were operated on by the galvanic écraseur, with 9 deaths; 7 by the wire écraseur, and 1 death (from pyæmia); 3 by the knife, no deaths; and 1 by ligature, fatal (from septicæmia). These figures, although few, condemned the galvanic écraseur. Did Mr. Stokes include the galvanic écraseur in his statistics. Mr. Barker agreed with Mr. MacCormac as to the preference to be given to the knife. The tongue should be split in the median line, and the base cut across, this measure allowing of the ready control of bleeding vessels and of their ligature in the ordinary way, and was far less open to danger of septic trouble than after crushing. Tracheotomy was sometimes called for in cases where much hæmorrhage was to be anticipated, or the diseased tissues were of wide extent. The risk from hæmorrhage could then be met by plugging the trachea, or by means of a sponge in the pharynx. In three cases he had no trouble in retaining a sponge there; but if the trachea were to be plugged Trendlenberg's tampon should be used, care being taken in its inflation, since, as Dr. Sémon had shown, its over-inflation caused dyspnœa.—Dr. DOUGLAS POWELL asked Mr. Barker what was meant by "septic" bronchitis and "septic" pneumonia. Did he imply that in such cases there was general septic infection; and were other organs affected, as in such septicæmia. If there were only bronchitis or pneumonia, that might possibly be produced by the passage of irritant matter into the bronchi or lung, and would be met by measures preventing such gravitation.—Mr. T. SMITH asked whether Mr. Stokes made any incision in the sublingual tissues. He believed that only a portion of the tongue could be pulled forward, and that the organ could not be wholly removed unless the subjacent tissues were divided. As he understood it, the septic pneumonia of these cases is produced by blood &c. trickling down the air-passages. The discharges were more copious after the use of the galvanic écraseur, owing to the slough it produces.—Mr. MARSH, in two or three instances of unilateral excision, had been disappointed with the result, the longitudinal cicatrix holding the tongue down, and the muscles of the remaining half turning it over, a condition giving rise to discomfort. It was plain that opinion was adverse to the galvanic cautery. He was acquainted with cases of secondary hæmorrhage following its use, and with one or two of fatal complications. By first dividing the muscles attaching the tongue to the lower jaw the base of the epiglottis can be reached. The experience of St. Bartholomew's Hospital did not accord with the statistics given by Mr. Barker.—Dr. COUPLAND urged Mr. Barker to reply to Dr. Powell's question. In post-mortem examination of cases of cancer of the tongue, foci of broncho-pneumonia were common, and to be attributed, not to septic infection in the ordinary sense, but to the inhalation of irritant and putrid materials.—Mr. BARKER said the question was an important one. No doubt sometimes there were pulmonary abscesses of truly pyæmic (embolic) kind; but the lungs might be also affected by blood trickling down the trachea during the operation, or fetid discharges similarly passing; also, he believed, by the simple inhalation of very acrid emanations from these wounds. In one instance the house-surgeon and nurse in attendance on the case became affected with sore-throat. He did not think these different modes of lung complication should be confused.—Dr. POWELL said the point was one of great practical importance. He had asked if there was any evidence of general blood-poisoning to which the lung disease was secondary. If in all such cases the infection was local, then a remedy might be sought in antiseptic inhalations and in enforcing a prone position, so that the blood and discharges might not pass down the air-passages.—Mr. BARKER said that in one case there was distinctly a general pyæmia, developing long after the operation, with abscesses in the liver and in the vicinity of the kidney, as well as the lung. In the other cases there was no involvement of other organs.—Mr. STOKES, in reply, said that he had not included Mr. Barker's statistics in his lists, but he had made a percentage mortality of about sixty in the cases of simple excision by the knife; and he admitted that it was remarkable that there should be apparently less danger from septicæmia in such cases than in those treated by the cautery. He was glad to find Mr. Marsh preferring the bilateral method, and could endorse what he had said as to the greater inconvenience both as regards deglutition and articulation resulting from one-half of the organ being excised than when both sides are removed. He knew of one case where the patient came to have the other half removed because of the difficulty in articulation and because it kept getting between his teeth. He was also pleased to hear Mr. Barker suggesting a preliminary division of the cheek, which greatly facilitates the operation. He had performed division of the sublingual tissues in such cases where the thickening and enlargement of the tongue called for it.

MANCHESTER MEDICAL SOCIETY.

AT the last meeting of this Society a number of very interesting cases were brought forward, notably one of Lymphatic Disease, affecting the left leg of a young girl, and causing great hypertrophy of the limb, shown by Mr. Walter Whitehead. Dr. Leech exhibited a case of Alopecia universalis, occurring in a man aged forty-one, the most careful examination of whose whole body failed to discover the slightest trace of hair. Dr. Helme showed a Sarcomatous Tumour of the Testicle, weighing twenty pounds, which he had removed post mortem from an old man aged seventy-one, who in life had declined operative interference. Dr. Lloyd Roberts exhibited two Ovarian Cysts, one of gigantic size, weighing thirty-four pounds, and the other, which was remarkable as being the smallest ovarian tumour he had ever removed, weighed five pounds; the woman from whom it was removed was only twenty-one years of age. Both patients are convalescent. Dr. Ransome read a very painstaking paper on Characteristics of Chest-movement in Chronic and Acute Cases of Phthisis, and their bearing on prognosis, illustrated by numerous diagrams, enlarged from tracings taken by the stethograph.

THE

GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

THE General Medical Council met on Tuesday last, April 26th, at 2 o'clock, Dr. Acland, President, in the chair. Four members were absent—Dr. Rolleston, Dr. Banks, Dr. Quain, and Dr. Haughton.

Dr. Alfred Henry McClintock was introduced by Mr. Macnamara as Crown Nominee for Ireland, for five years from March 2nd, in place of Dr. Hudson, deceased.

Mr. James Spence was introduced by Mr. Turner as representative of the Royal College of Surgeons of Edinburgh, for three years from Feb. 17th, in place of Dr. Andrew Wood, deceased.

The PRESIDENT delivered the following address :—

The business for which it has been thought desirable to summon the Council for this its thirty-second session need not detain it long. In the same way that it was necessary that the Council should meet last February to make legal the issue of a correct Dentists' Register, and only thus to avoid inflicting hardship on members of the dental profession, possible injury to the public, or violation of the Dentists Act, so now it has appeared to members of the Council and myself of urgency to consider without delay certain questions affecting the education and examinations of schools and colleges throughout the country. In consequence of the funeral of the Earl of Beaconsfield, which takes place this afternoon, it might have been in accordance with public sentiment that our proceedings should have been this day deferred. But seeing that the deceased statesman has left the most express desire that his obsequies should be conducted privately, and not in the metropolis, it has appeared more in harmony with his desire, and more agreeable to the Englishman's sense of steady duty, to proceed with the work and the arrangements of the day, undisturbed by any thoughts but those which hover about the close of a long life that has largely influenced our nation and age. And let it be added in this Council, that it has good reason to express its gratitude for the steady and courteous manner in which, under circumstances of much difficulty, the Earl's Government, through His Grace the Duke of Richmond and Gordon, laboured to carry through Parliament (and, on two occasions, successfully through the House of Lords) Bills for the settlement of vexed questions in regard to medical education and examination, the rights of colonial practitioners, and several other particulars. I need only refer to the Act for the Education and Registration of the Profession of Dentists, which, like every such initial measure, presented complications that could not be at once removed. It is to be regretted that the time which seemed suitable to many has not been so to all. The Council will remember that the meeting in this Easter recess was much urged by Professor Haughton, a proposal to which reference will hereafter be made. It has indeed been pressed upon me by more than one person whose opinion I value, that it is not desirable, pending the Report of the Royal Commission, which is shortly to meet, that the Council should continue the educational work already in hand, or initiate any other matters, however urgent. Had I acted on this opinion I am satisfied I should have incurred, and justly, the displeasure of the Council. It is true enough that for ten years the Council has been hampered, and the medical profession disturbed by agitation, which had no real bearing upon duties imposed on the Council by the Medical Act of 1858, except so far as to keep up a constant feeling of uncertainty as to the nature of the examining boards of the future. This circumstance made it impossible to bring to a successful termination questions which had long occupied the attention of the Council and of the licensing bodies throughout the country. Neither this agitation, nor the expectation of a more permanent settlement of those questions through an investigation of the working of the Medical Acts by a Royal Commission, would now justify us in causing suspense or uncertainty as regards educational regulations in schools frequented by youths destined for the medical profession, to any greater extent than may be absolutely necessary. It will be well for the Council to bear in mind on the present occasion the report which was presented by Dr. Storrar so far back as August of the year 1859, on the subject of general education. The principle which pervaded that report was that the superintendence of the general education of the medical profession should be left to the great national educational bodies, meaning thereby the universities of the United Kingdom. This principle was based upon the conviction, first, that intellectual fitness and a good general education were of primary importance in order to enable youths of average intelligence to master the facts and laws of physical science, and of the principles and practice of medicine directly and indirectly connected with them; and, secondly, that in the then transitional state of education in Europe, and notably in Great Britain and Ireland, it was of consequence to the future culture and social status of the medical student that his education should not be inferior to, but as far as possible the same as, that of the educated classes of society. Upon the whole the Council has never, in the twenty-two years that have since elapsed, wavered in this opinion. It has persistently maintained, time after time, that a sound education in arts should of necessity precede the entrance on professional studies, and that the purely medical institutions should neither conduct, nor be judges of, the nature and extent of attainments in preliminary education. This opinion, however, did not and could not exempt the Council from the obligation to see that the conditions which its members, as representative professional men from every part of the country, held to be desirable were fulfilled by the Examining Boards. Of these Boards no fewer than seventy-three, besides the "abiturienten" examinations and "entrance examinations" on the Continent are at this moment on the list recognised by the Council. It became accordingly, in the judgment of the Council, its duty to determine the subjects which should be compulsory in any arts examination for medical students. The Council issued last year a notice embodying its then conclusions, pointing out to the Arts Examining Boards the [subjects which they desire to be comprised in the preliminary education of a medical man, and without a knowledge of which students should not be allowed to enter on medical study. This list of subjects is to be in force at the end of the present year. It is the effect of this notice to which your attention has to be directed on the present occasion. There can be no doubt that the list is a good one, and that it implies a great advance in the educational arrangements of schools, and also in the requirements from the students. But you will have evidence brought before you that it is not easy and perhaps not possible to carry out the scheme in its entirety on so short a notice. The arrangements for examination now existing throughout the country are extensive and elaborate, and cannot at once be altered, even if should be considered desirable that they should be altered. Nor can the Council compel the alterations. And further, it is to be admitted that there are various ways of forming a true and firm character in a youth, and of training him to habits of observation and accuracy. To specialise our young medical students into a class at a very early period, so as to remove them from the best devised methods of higher education, whatever that may be in the judgment of the educators of the nation, would in the end prove disastrous to the medical profession. The specialisation asserts itself in most men with sufficient force at a later period of life. This subject is to some extent further complicated by the expressed wish of the Council that there should be a special examination in the rudiments of natural science—physical, chemical, and biological—before the student enters on the purely medical curricula. On this proposal there have been received, from the various medical licensing bodies, communications which form the subject of a special report from the committee appointed for the purpose, and therefore it would be out of place here to comment upon them in detail. But I cannot forbear from stating at once that several of the answers show the risks that would attend any instant attempt at coercive regulations in this matter. The Council may have to consider whether it would be expedient to defer the exact requirement of the Council's list of subjects proposed for general education till after the report of the forthcoming commission. This might be desirable in the true interests of the schools for the purpose of securing the steadiness and uniformity in the examinations. The report of the Executive Committee dealing with the letters from Cambridge that are presented to you to-day, suggests even more than this, as regards the local and other examinations of the two old universities. But this does not meet the whole difficulties of the case. Other bodies besides these may send in similar applications. And it might be imprudent to guarantee the same confidence in all applying Boards. These and other considerations must make all wish that the Royal Commission may quickly and with completeness settle what changes, if any, are to be made in the Examining Boards of the kingdom; and to what extent it is desirable that the Central Council should be empowered to enforce detailed regulations on all local institutions. Letters of importance from Mr. Tomes and others will be laid before you. In the construction of the Dentists' Register a difficulty arose with regard to the real fitness of many persons who professed to be in practice and to possess a legal qualification as dentists. This became at once a question of legal interpretation of an existing Act rather than one which this Council has at heart —namely, the education and professional character of registered dentists. When the Council met in February for purposes connected with the Dentists Act only, they decided in accordance with the legal opinions laid before them, giving their judgment upon the facts as furnished to them. One of the results at which the Council had previously arrived was to exclude from the Register all titles other than those definitely stating a qualification in dentistry. It is not to be wondered at that persons such as Mr. Tomes, a Fellow of the Royal Society and an eminent member of the College of Surgeons, and persons who are Fellows of the Royal College of Surgeons, should resent as a hardship, and even an injury, that a title so honourable as a Fellow of the College of Surgeons of England, implying without question surgical knowledge and education of real value for the purposes of the higher problems of dentistry, should not be entered in the Dentists' Register. On the legal advice we have such knowledge, and such titles are considered not to be higher in respect of dentistry in the terms of the Act. If this be so, it is certainly a question for argument whether the Act should not be amended. I do not presume to offer the opinion that the Council would act illegally if it inserted such titles as higher titles, nor to say that a penalty would accrue if it did. The value of so-called higher titles has been made the subject of a question in the House of Commons, and will doubtless be considered at some future occasion. A motion will be brought before you on this subject so far as it affects the Dentists Act. Cases of alleged misconduct in a professional respect will be brought before you for decision in the course of the meeting. One of them, that of Dr. Levenston, asks to be heard by counsel; it has been of long standing, and should for obvious reasons, if possible, be disposed of. Since the lamented death of Dr. Andrew Wood, the Executive Committee has considered some of the arrangements according to which, from usage, the business of the Council has been hitherto conducted. Were it not for the appointment of the Royal Commission, it would be prepared to suggest changes which would tend to diminish expense and facilitate the work of the Council, both at its meetings and in the intervals of its business. Some of these have reference to the times of meeting of the Council and of the Executive Committee, to the constitution and duties of Standing Committees, and to the powers of Committees generally—all matters already brought to your notice by Mr. Teale and by others. I do not venture to indicate what an experience, derived from the whole history of the Council, has taught in these directions. There are few here who must not have often deplored the loss of time and the abstraction from their real duties which Parliamentary agitation, apparently attractive to some minds, has caused within the last ten years. It has rendered a fixed time of meeting, whether for the Council or for the Executive Committee, virtually impossible. It has forced the Council to spend whole meetings in considering whether improvements could be made in machinery, when they would have endeavoured to work the machinery which Parliament had made, and it has practically had the effect, through long delay and by reason of deferred expectation, of throwing several institutions charged with the medical education of the country back upon themselves, and has checked mutual co-operation, which ten years ago seemed not only possible, but certain. It will hereafter be a matter of astonishment that two Governments so powerful as those of Mr. Gladstone and Lord Beaconsfield should, after much labour and full mastery of the subject, have carried Bills in three successive years—1871, 1877, 1878—through the House of Lords, and should not have thought it well to risk opposition in the House of Commons to carefully considered Bills which gave increased powers, and rectified anomalies at home and in the colonies. To one other subject only would I draw your attention—the visitation of the examinations that is now in operation. You need not be reminded of the valuable Reports which were prepared on the condition of all the examinations throughout the kingdom in the years 1865–6, 1868, 1873–5, nor of the reports on the state and needs of education from the principal teachers in all departments of medical science and practice in the chief schools of the country.[1] The Executive Committee, acting on your instructions, has made arrangements for the visitation this year of the Colleges of Physicians and of Surgeons in England, in Scotland, and in Ireland respectively. The visitors are Mr. Teale, Crown Nominee on the Council, Professor Gairdner of Glasgow, and Professor Stokes of Dublin. These gentlemen have undertaken that which the Committee could hardly venture to ask, to visit all those bodies in the course of the present year, and to state a full and careful educational report—the conclusions at which they arrive on the state of medical education, actual and comparative, according to the data which are obtained through their inspection. It would not be well here or now to speak of the qualifications of these eminent persons, of the debt which the Council and the public will owe to them, nor of the value which will be attached to their services. The comparison between England, Scotland, and Ireland, made by the same visitors, will be far more instructive than a separate inspection by different visitors could have been. And the value will be further enhanced by reference to the opinions of the numerous teachers recorded in 1869, as showing the progress of ideas, the results of experience, and the nature and extent of alterations that are needed. It is not possible to forecast what changes are yet needed in teaching so intricate a branch of knowledge as the science and practice of medicine. Pessimists no doubt love to dwell on failure; but those who know the high character of a large proportion of our modern medical students, the immense progress of medical science, whether in the prevention, or cure, or alleviation of disease, in the last twenty-five years, are not likely to despair of the future, or to doubt that the foundation has been laid for successful and united effort towards greater improvements and disinterested work for public good. These are shown in the progress of gained scientific truth by more logical methods of thought, and by more widely diffused skill, by reason of better general education in the application of both to the needs of common life. It remains for me only to add a few words in reference to the subject of "Conjoint Boards," or "State Examinations," a subject which, at the present moment, is, as for ten years it has been, entirely unsettled. It is well known to the Council that a complete board, with all the regulations necessary for its management, has been long agreed to by all the medical authorities in England. But, as years passed by and legislation failed, it became clear that, so long as no such combined or State Examination existed in any form in Scotland or Ireland, the English board was not likely to come into operation. The Medical Act of 1858 gave permissive powers of combination to the nineteen licensing bodies. It gave no compulsory powers to the Council. To the majority of this Council, therefore, there appears, without legislation, no prospect of change, however, desirable. Under these circumstances the Council has done, and is doing, what it can by stimulating education and inspecting examinations, both of which have been much improved. In some respects the examinations may be becoming too severe for many students, unless systematic and careful measures can be taken to secure in the weaker schools as good opportunities and as effective teaching as in the best. To ask this is to ask what may be impossible; therefore, at present, the examination test, however imperfect an instrument, must be chiefly relied upon. Competition in schools, if the examining boards can be made thoroughly judicious for attaining the object in view—viz., sufficient practical professional skill—will simply mean a competition for ensuring the best education. The Royal Commission will doubtless seek a solution of this problem with the least possible delay, and we may be sure will endeavour to leave the administration of its recommendations to the executive best adapted to the existing state of things and to the public interest. It would not become me to suggest any fresh action in new matters on the part of the Council, pending the labours of the Commission, which this Council has every reason to desire may be speedy, complete, and final. We have at this meeting to continue steadily, and, it is hoped, rapidly, the discharge of the necessary and appointed duties which we have in hand.

---

[1] Reports on Professional Education and Examination, 1869.

On the motion of Mr. TURNER, seconded by Mr. SIMON, the address was ordered to be entered on the minutes.

The Business Committee, consisting of Dr. Pitman (chairman), Dr. Aquilla Smith, and Dr. Haldane, was reappointed, as was also the Finance Committee, consisting of Dr. Quain (chairman), Dr. Aquilla Smith, Dr. Pitman, and Dr. Scott Orr.

Dr. PITMAN moved, "That a committee be appointed to consider and report at a future meeting on the preparation of the next edition of the Pharmacopœia, and that it consist of the following members, Dr. Quain (chairman), Dr. Aquilla Smith, Dr. Leet, Dr. Pitman, Mr. Macnamara, Dr. Haldane, and Mr. Bradford." He expressed a hope that the Council would not consider that the object of this motion was to take immediate steps for the republication of a new edition of the Pharmacopœia, because there were at present about 4000 copies on hand. For nineteen years the committee was appointed and reported annually; but by some oversight a few years ago that was not done. There was, therefore, now no such committee in existence to perform one of the duties specially required by the Medical Act. The present Pharmacopœia was published about fourteen years ago.

Sir WILLIAM GULL seconded the motion. He considered that it was a disgrace to the Council to have gone so long without improving the Pharmacopœia. To make it of any use to the profession the committee ought to prepare an addendum year by year containing all new remedies.

Dr. AQUILLA SMITH approved of Sir William Gull's recommendation.

Mr. TURNER suggested the addition of Sir William Gull's name to the committee.

After a few remarks from Mr. Macnamara and Mr. Simon, the motion was agreed to, with the addition of Sir William Gull's name.

On the motion of Sir WM. GULL, seconded by Dr. PYLE, it was agreed, "That it be an instruction to that committee to report to this Council year by year as to addenda to be made to the Pharmacopœia."

A table showing the results of professional examinations held in 1880 for qualifications granted under the Medical Act by the bodies named in Schedule A was laid on the table and ordered to be entered on the minutes.

The usual returns from the Director-General of the Medical Department of the Navy, and from the Army Medical Department, were received, and ordered to be entered on the minutes.

A communication was received from the King and Queen's College of Physicians in Ireland, in accordance with the recommendation of the Council to the licensing bodies to instruct examiners in professional subjects to report to them any cases in which decided ignorance in general education had been displayed by the candidates, with the name of the board or boards before which the preliminary examinations had been passed. The communication stated that in the examinations conducted by the College in 1880 eight candidates for the licence in medicine had been deficient in orthography, of whom six held the licence of the Surgery of the Royal College of Surgeons in Ireland, and two that of the Royal College of Surgeons of England.

Dr. SMITH called attention to the fact that the King and Queen's College of Physicians in Ireland was the only body that had complied with the recommendation of the Council, and added, in explanation of the largeness of the proportion of the candidates referred to holding the licence of the Royal College of Surgeons in Ireland, that three-fourths of the candidates coming before the King and Queen's College of Physicians in Ireland were licentiates of the former body.

Mr. TURNER pointed out that the King and Queen's College of Physicians had not complied with the recommendation of the Council as to the bodies which had passed the candidates in preliminary examinations.

Dr. HALDANE asked if the candidates in question had been rejected by the King and Queen's College of Physicians.

Dr. SMITH.—Certainly not.

On the motion of Sir WM. GULL, it was resolved that the College be requested to furnish the Council with the names of the bodies before which the candidates had passed their preliminary examination.

A communication was read from the Royal College of Surgeons stating that the Council of the College had decided that the preliminary examinations for the diplomas of the College, at present conducted by the College of Preceptors, under the authority of the College, should cease from and after Dec. 31st, 1881. A letter was also read from the College of Preceptors on the same subject, expressing a hope that means would be taken to replace the examinations by some special scheme of a similar character, placed under the control of the Medical Council, and adding that it would give pleasure to the Council of the College if it could be in any way instrumental in carrying such scheme into effect. A report on this subject was presented by the Executive Committee, but before it was read,

Dr. STORRAR complained that the Executive Committee had reported upon a subject which had not been referred to it. The committee, he said, was becoming an *imperium in imperio*, and was practically superseding the action of the Branch Council for England.

Dr. PYLE said he was about to give notice of a question as to whether the action of the Executive Committee was in accordance with the standing orders of the Council.

The PRESIDENT said that Standing Order No. 8 stated, "The Executive Committee shall consider and prepare reports upon any subjects that may seem to require the attention of the Medical Council"; and the object of the committee was to expedite the business of the Council.

Dr. HUMPHRY said that if the committee had not taken action in the matter nothing would probably have been done in reference to it till next year, when the question would be formally referred to the committee.

Dr. STORRAR said the College of Preceptors might have been asked to wait upon the Council to-morrow; but he objected to the whole character of the proceedings of the Executive Commtttee having been altered. Of late years several matters had been considered by the Executive Committee which ought properly to have come before the Branch Council for England. The result had been that the Branch Council had had no meeting for a whole year.

Dr. SMITH said formerly the Executive Committee consisted entirely of English members, but now the objections to the committee had been removed by the change in its constitution.

Dr. PITMAN said it would be only common courtesy to let the Report be read. Any objections to it would be heard afterwards.

The Report was then read.

REPORT TO THE GENERAL COUNCIL BY THE EXECUTIVE COMMITTEE.

In regard to the letter received from the Royal College of Surgeons of England (Clause 11 of this programme), and the foregoing letters (in Clauses 14 and 16) from the College of Preceptors, the Executive Committee reports to the General Council as follows:—"The Examinations in General Preliminary Education under the authority of the Royal College of Surgeons previously to 1875 were held in June and December. Since that time they have been held in March and September, because those months were found to be more suitable to the medical student, as they immediately precede the summer and winter sessions; and the convenience of this arrangement has been proved by the great number of candidates who have resorted to them. It is therefore important that preliminary examinations, suitable and accessible to intending medical students, should be held in those months. After the present year, the 'Registration

Examination for medical students' by the University of Durham, and the 'Examination in Arts' by the Apothecaries' Society of London, will be the only examinations in England which take place in those months. If the often repeated recommendation of the Medical Council, that the preliminary examination of medical students should be conducted by the National Educational and Examining Bodies, is to be carried out in England, it is essential that examinations suitable for intending medical students should be conducted at times convenient to them. The committee would gladly have been able to report that the University Local Examinations and the Oxford and Cambridge Schools Board Examinations are able to supply the deficiency. Those examinations are held in May, June, July, and December, which are the months most suitable to the several schools; and they will probably be more and more resorted to as avenues to registration by medical students; but the times at which they are at present held are inconvenient to many medical students. The letter from the Secretary to the College of Preceptors indicates that that body is willing to institute an examination similar to that which it has conducted under the authority of the College of Surgeons, and by means of local centres to render it more accessible to most medical students. The committee therefore recommends that the Council should delegate to the Executive Committee to make arrangements with bodies willing to institute preliminary examinations suitable for medical students."

The Draft Scheme was ordered to be entered on the minutes, and the Report was received and also ordered to be entered on the minutes.

The Council then proceeded to consider the charges against Samuel Levenston, M.D., of 6, Hope-street, Glasgow. Mr. Anderson appeared as counsel for Dr. Levenston, and Mr. Dickens attended on behalf of the Council as a legal assessor.

Mr. OUVRY read a declaration by a Mr. Bayne, an officer of the Glasgow Mendicity Society, in which he stated that he had frequently in the streets of Glasgow been handed copies of handbills and pamphlets by Dr. Levenston's distributors. Specimens of these were produced and verified by the witness. In other portions of the document there were statements of what Mr. Bayne had heard about the results of Dr. Levenston's treatment.

An affidavit by a man residing near Galashiels was also read. It stated that he had paid five guineas to Dr. Levenston for a parcel containing eight bottles of medicine, and subsequently fifteen guineas for three other parcels. He was not benefited by the medicine, but, on the contrary, was getting into a state of despondency.

Mr. ANDERSON protested against the document being laid before the Council, on the grounds that the notice with which Dr. Levenston had been served contained no intimation of such a charge, and that the person was not present to be cross-examined.

Dr. S. LEVENSTON, in answer to questions by Mr. Anderson, said some of the pamphlets produced had been out of print for a great number of years. A handbill, headed "Elixir of Life," had been circulated in the streets of Glasgow for the last twenty years. His directions were that it should be given only to men. A book, entitled "Nervous Debility, its only Cause," was also distributed in the same manner. The "Elixir of Life" was a strong tonic, sold in bottles. His charge was 35*s.* per parcel of four bottles. He had no recollection of the case referred to from Galashiels, and he kept no books to which he could refer. He had no knowledge of ever having been asked to return the fifteen guineas. If he had expected such an examination as the present he could have brought letters from persons who had been benefited by his treatment. He certainly did not think that the pamphlet on "Nervous Debility" was morally injurious to the persons who read it. To the best of his ability he had given honest and good advice, as an ordinary practitioner, to those who applied to him.

In cross-examination by Mr. OUVRY, the witness said he did not believe that any of his agents had ever sent one of the pamphlets to an educational establishment in Belfast. The medicine he prescribed was the result of long study. He did not think he was entitled to answer the question as to whether it consisted largely of proof spirit.

After a brief discussion between Mr. ANDERSON and Mr. OUVRY the latter withdrew the deposition from Galashiels, and consented that it should not be considered proper evidence.

Mr. ANDERSON then addressed the Council on behalf of Dr. Levenston. He urged that "a due inquiry," as required by the Act, required something more than the statements which had been laid before the Council, many of which were mere hearsay statements that ought never to have been made. He also complained that Mr. Ouvry had not furnished Dr. Levenston with a copy of the documents which were to be brought forward against him. Reference had been made to Dr. Levenston's "victims," but none of them had been brought before the Council for examination, and no adequate evidence of "infamous conduct" had been forthcoming. It had been said by a witness that the medicines were "worthless," but no inquiry had been proved with reference to the accuracy of that statement. Dr. Levenston's conduct might have been unprofessional, and it was a matter of regret that he should have circulated the bills and pamphlets produced; but that, he maintained, was not infamous conduct within the meaning of the Act. A vulgar, puffing announcement of some quack medicine, such as Dr. Levenston had put forth, was certainly unprofessional, but nothing more. If the medicine itself had been worthless, evidence of it would have been given, as he had no doubt that some tests had been made. As to the pamphlet on self-abuse, the subject was no doubt one from which they naturally shrank; but it could not be ignored; it must be treated medically, and he maintained that the work in question, which contained salutary warnings to those who needed them, had nothing in it which could be considered as disgusting or infamous, as alleged in the declaration. The habit in question was a disgusting one, but a medical essay upon it could not be so styled. The manner of its circulation might be open to question; but could it be contended that the circulation in large numbers of a pamphlet in itself unobjectionable was infamous conduct within the meaning of the Act of Parliament?

Mr. OUVRY, in reply, called attention to the fact that the circulation of the pamphlets had been admitted, and said that the matter now rested with the Council.

Strangers were then directed to withdraw while the Council deliberated. At a few minutes to six the doors were again opened, when, on the motion of Dr. PITMAN, seconded by Dr. HUMPHRY, the following communication from the Privy Council Office was referred to a small committee to be considered and reported upon.

"Council Office, March 9th, 1881.

"SIR,—I am directed by the Lord President of the Council to transmit to you the enclosed copy of the latest regulations published respecting the conduct of Swiss Medical Examinations, and I am to request that you will lay that document before the Medical Council, and that you will move that body to favour his Lordship with their remarks on the subject.

"I am, Sir, your obedient servant,

"C. L. PEEL.

"To the Registrar of the General Medical Council."

This letter was accompanied by a pamphlet of thirty closely-printed pages, containing the "Règlement pour les Examens de Médecine Féderaux."

The PRESIDENT then announced that the Council would resume the consideration of Dr. Levenston's case to-morrow, and the Council adjourned.

WEDNESDAY, APRIL 27TH.

At the meeting of the Council to-day, the consideration of the case of Dr. Levenston was resumed. The Council deliberated in private, and ultimately came to the following decision: "That Samuel Levenston, M.D., is adjudged, after due inquiry, to have been guilty of infamous conduct in a professional respect. That, as it has been proved to the satisfaction of the General Medical Council, that Samuel Levenston has been guilty of infamous conduct in a professional respect, the Council does, by this order in writing, direct his name to be erased from the Medical Register, and gives orders to the registrar to erase his name accordingly."

Dr. HUMPHRY, in moving the adoption of the recommendation contained in the report of the Executive Committee respecting preliminary examinations, referred to the recent announcement of the College of Surgeons as to the abandonment of the examinations of the College of Preceptors. That announcement, he said, was a very important one, inasmuch as a very large proportion of the medical students in England resorted to that examination. The College of Surgeons had renounced the power of superintending the preliminary examination of those students, and at the same time renounced not inconsiderable pecuniary advantages in following the recommendation of the Council. It had often been said that the corporate bodies did not attend to the Council's recommendations; but in the case of the College of Surgeons there had been a great concession to the wishes of the Council. It could hardly be supposed that a body like that would have adopted that course had it not been for the relations existing between the College and the Council, maintained by means of its representative. The College had expressed a hope that under the circumstances the Medical Council would, as far as possible, require that the examinations recognised in lieu of those abandoned should be held at such times and places as would be most convenient for the candidates—viz., in March and September. The committee had ascertained that the greater number of examinations were not fixed at those times. The only examinations in September were those of the University of Durham and the Apothecaries' Society. In abandoning the examinations of the College of Preceptors the College of Surgeons hoped that they would be continued, not by the other corporations, but by the general examining bodies of the United Kingdom. The Oxford and Cambridge School Board held an examination in July, but their requirements were too high for ordinary medical students, and a proposal was about to come before the Board to have an examination in July for a certificate of a lower character. It had been proposed by the College of Preceptors to institute another examination in place of the one which had been given up. The Executive Committee had considered the subject, and thought that it required deliberation as to whether, if the examinations were continued, they should be subject to some sort of visitation. Dr. Humphry concluded by proposing "that it be delegated to the Executive Committee to make arrangements with bodies willing to institute preliminary examinations suitable for medical students."

Sir WM. GULL seconded the motion. He believed that in the making of a violin the first requisite was to select the wood, and in an intellectual profession like the medical the first requisite was to select the very best material they could find. He had before suggested that there should be an examination which would cut off 33 per cent.; and the late Professor Stokes had expressed his belief that if that were done all the rest of the examination might go. He was glad that the College of Surgeons had given up the examination hitherto conducted, but it ought not now to be left to chance. As to the proposed examination of the College of Preceptors, if it were adopted by the Council it ought certainly to be subject to some supervision. They could not supervise all the examinations, but they might do what they could in that direction.

Mr. SIMON thought that the matter ought not to be delegated to the Executive Committee without some fundamental instructions. The preliminary education required was not one specially designed for medical students, but an examination common to all among the educated classes; and hence the Council had been anxious to have the examinations conducted by the general educational bodies of the country. The College of Preceptors had a general examination, and it could arrange for one of them at a convenient time for medical students, without arranging any special examination for such students alone.

Dr. QUAIN hoped that the Council would not go back to the old system of preliminary examination by the corporations. Very few of the bodies now retained the examinations; and as to the suggestion of the College of Preceptors, for a special examination for medical students, it was the most monstrous proposal that could be made.

Dr. STORRAR referred to the appointment of a committee of the Council twenty-two years ago on the subject of arts education, and to the struggle that had been required to enforce such education for medical students—not a special one, but one suitable for all classes. The exact subjects were not so important as the adoption of *some* means of mental discipline; and the committee expressed its opinion that no new educational machinery was required. Every effort had been made to induce the Medical Corporations to give up the arts examinations, and he was highly gratified at the example which had been set by the College of Surgeons in that direction. The proper course was for the Council to recognise the examinations of the educational bodies, including those of the College of Preceptors.

Sir JAMES PAGET said the object of the committee was only to recommend that the examinations should be so adjusted as to include all the subjects required by the Council, and to be held at the most convenient times.

Dr. HUMPHRY said it was never intended that the examination should be of a special character.

The PRESIDENT said he had never understood the recommendation otherwise than in the sense expressed by Sir James Paget, that the examinations should include all the subjects required by the Council, and be held at convenient times.

Dr. STORRAR regretted that the Council had last year increased the number of subjects of examination, believing as he did that it would have the result of sacrificing thoroughness to variety. He thought there should be a preliminary arts examination in one or two subjects, and afterwards a preliminary science examination. He wished to ask Sir J. Paget whether the College of Surgeons, in parting with the special examination of the College of Preceptors, would recognise the preliminary examinations of the other medical bodies?

Sir JAMES PAGET said the College wished to discuss the whole subject of preliminary examination. It required the registration of the student by the Council. There were certain cases of students coming from India wishing to study medicine, and in rare cases of the kind the College reserved to itself the right of deciding as to their admission.

Dr. STORRAR hoped that the College of Surgeons would have nothing whatever to do with the preliminary examinations of other medical bodies. For himself he would sweep away a large number of the seventy-three bodies now recognised. They had recognised certain universities in the American colonies, in the United States, in India, and at the Cape of Good Hope; but those recognitions should, he thought, cease, and the Branch Council could deal with individual cases as they presented themselves. If an Indian student had received a mental training through the medium of Sanscrit, his case could be separately considered and decided by the Branch Council. If the Medical Council would divide itself into two committees, one to consider the subject of preliminary arts education, and the other to consider the preliminary science examination, the result, he thought, would be very profitable.

Dr. HUMPHRY said he would substitute the following motion for that which he had made: "That the Executive Committee be requested to communicate with the universities of the United Kingdom and with the College of Preceptors with a view to promote that such of their examinations as most nearly correspond to the minimum requirements of the Medical Council in respect to preliminary education, and are open to all classes of candidates, should be held, or in part held, at times which should be generally convenient to medical students intending to enter upon their professional curriculum in either the winter or summer sessions."

Mr. MACNAMARA hoped that the Council would not be satisfied with written to the exclusion of *vivâ voce* examinations. The Council of the College of Surgeons in Ireland would willingly resign their functions to other hands, but there were great difficulties in the way, and they would not be contented with written examinations only. The present examination of the College was a very complete one, and included subjects, as required by the Medical Council, not required by the university itself. The Schools of the Board of National Education gave instruction in all the required subjects except Greek, but the difficulty was to get an Examining Board.

Dr. Humphry's motion was then put and adopted.

The following report was presented by the Executive Committee with reference to certain letters that had been received from the Oxford and Cambridge Schools Examination Board, the Cambridge University Local Examinations Board, the University of Cambridge, and the Medical Committee of the Hebdomadal Council of Oxford, on the subject of preliminary examination, in reply to a circular letter addressed to them by the Council:—

"It appears that if the new regulations with regard to preliminary examination passed during the last year's session of the Council be strictly enforced, none of the examinations conducted by the University of Cambridge, and the same may be said of those conducted by the University of Oxford, will fulfil the required conditions. It is not probable that those examinations could be altered into conformity with the new regulations; the Executive Committe, therefore, bearing also in mind the recommendation of the Council that 'it is desirable that the examination in general education should be left to the universities, and to such other bodies engaged in general education and examination as may from time to time be approved by this Council,' recommends that the examinations in general education conducted by universities should be accepted as heretofore."

Dr. HALDANE, in moving the adoption of the recommendation of the report, said that some of the university examinations were of a higher standard than were required by the Council, but did not in all respects conform to the letter of the Council's regulations as to the subjects included. In some cases dynamics, dictation, and composition did not form part of the examination, but as the universities had acted in the spirit of the recommendations of the Council, he thought that the examinations should be recognised as heretofore.

Mr. TEALE seconded the motion.

Dr. STORRAR asked if the matter had been referred to the Executive Committee.

Dr. HALDANE said it had not; but the committee thought that time would be saved by their considering the letters that had been received in reply to the circular, and bringing the matter before the Council.

Dr. STORRAR said he heartily approved of the proposal to recognise the university examinations, though they did not embrace all the required subjects, but he renewed his protest against the system which had crept into the proceedings of the Executive Committee, in first dealing with subjects of that character and then handing them over to the Council for consideration. He would vote for the proposed recognition, but not for the report of the Executive Committee.

Dr. HALDANE thought that would amount to a distinct censure upon the Executive Committee.

Dr. FERGUS said the standing orders required the Executive Committee to "prepare reports upon any subjects requiring the attention of the Council."

Dr. STORRAR objected to the business of the Council being "filtered" through the Executive Committee.

Dr. HUMPHRY said that it had often been said that the business of the Council would be better done if it were considered and arranged beforehand; and the Executive Committee was the body required by the standing orders to do that very work. It was for the Council to accept or not the recommendations of the committee. The fees of the Executive Committee had been increased, and he imagined that it was expected that their duties should be increased also.

Dr. SMITH said that Dr. Storrar's amendment involved a censure upon the Executive Committee, and he could not therefore vote for it.

Mr. SIMON thought the committee should distinguish between the preparation of matter for consideration by the Council and the initiation of judgment. He thought it would be better to adopt the recommendation proposed as a separate motion, but not as part of the report. A report was often argumentative, and they might not be able to adopt the arguments as presented.

The PRESIDENT expressed his concurrence with the views of Mr. Simon. He did not think the proposal involved any censure on the committee, but believed that the course proposed by Mr. Simon was the most convenient one to adopt. The committee had only intended to frame a motion for discussion, and not to express any judgment in the matter.

Dr. HALDANE said he would withdraw his motion, and substitute, "That the examinations in general education conducted by the universities be accepted as heretofore."

Mr. MACNAMARA said the Council had spent a good deal of time last year in considering the subjects which the student should be acquainted with, one of the most important of which was "The Elementary Mechanics of Solids and Fluids"; and now it was proposed to undo what the Council had already done, several of the universities not examining in the subjects required by the Council.

Mr. TURNER thought that the motion should be enlarged, and that the Council should distinctly express its opinion that if any of the university examinations which it was proposed to accept did not include the subject of the Elementary Mechanics of Solids and Fluids, the candidate should be required to pass an examination in that subject before he was admitted to his professional examination.

Dr. HALDANE'S motion was then carried, with the following addition suggested by Dr. Storrar: "But that if in any of these examinations the subjects of Elementary Mechanics of Solids and Fluids are not included, a knowledge of those subjects should be required at a subsequent examination."

Mr. SIMON said that the first-class examination of the College of Preceptors was accepted, of course, with the same condition as had been put upon the universities. It was, in reality, a higher examination than was required by the Council, and he would suggest, for the consideration of the Executive Committee, whether the second-class examination of the College might not also be accepted. It was somewhat under the required standard, but that might be compensated for by requiring the candidate to pass in some of the higher divisions of the examination.

The following report was brought up from the Executive Committee:—

"The Executive Committee begs to call the attention of the General Council to cases of students, coming from India, who have passed the Matriculation Examination at the several Indian universities. The examination at these universities includes Latin as an optional subject, but the students, as a rule, take up Sanscrit or some other language in place of Latin. The regulations of the Council require that the Certificate of Examination from these universities should include Latin. Certain students from Bombay who have passed the university examination there, not including Latin, have applied to be allowed to enter for examination, on condition that they shall now pass an examination in Latin, and this the Executive Committee has acceded to. Certain other students in the same condition have applied to the Executive Committee to allow them to enter for examination without any examination in Latin. The committee, under the special circumstances of the case, has considered that the passing in Sanscrit may be accepted in place of Latin, and has granted their request. As, however, this is not in accordance with the words of the recommendation of the General Council on education and examination, the Executive Committee thinks it right to submit the matter to the General Council, in order that the matter may be amended, and a rule laid down for the future guide of the committee. The committee suggests that the General Council delegate to the Executive Committee power to make exception to the recommendations on education and examination, in cases in which such exception shall seem to them to be reasonable."

Dr. STORRAR inquired how the question had come before the Executive Committee.

Dr. HUMPHRY said that the cases referred to in the report had from time to time been brought before the Executive Committee. Strictly they should, no doubt, have been brought before the English Branch Council (Hear, hear, from Dr. Storrar), but the Executive Committee had thought it better to assume the responsibility of making the exemptions instead of calling together the Branch Council for that particular purpose, which would have involved considerable expense, and would have been an unnecessary piece of red-tapeism.

Dr. STORRAR said he had given notice of a motion for the reconsideration of the standing orders relating to the proceedings of the Executive Committee.

Mr. TURNER did not wish to enter into the pretty quarrel which was impending, but would leave the bodies concerned to fight it out between themselves. He would only say that if the recommendation of the committee were adopted, the Scotch Branch Council would be put into a difficult position. It had often had similar cases brought before it of young men coming from the Indian universities without passing an examination in Latin, and it had positively refused over and over again to register them, thus complying with the recommendations issued by the Medical Council. Now, however, it appeared that the Executive Committee had been overriding the resolutions, not of the English Branch Council, but of the General Medical Council itself. With all deference to the committee, he could not help thinking that they had taken a liberty with the Council's recommendations which they had no right to take, and which certainly had put the Scotch Branch Council in a difficult position.

The PRESIDENT said, in reference to the motion of which Dr. Storrar had given notice, that the Executive Committee would only be too glad to have some of the difficult points that had arisen definitely settled. They were anxious to do their best under the circumstances, and desired to have their powers clearly defined.

Dr. STORRAR said that, in taking up the cudgels against the Executive Committee, he did not wish to reflect upon the members individually, who, he had no doubt, had done what they considered their duty; but, filling somewhat the position of Her Majesty's Opposition, he hoped it would not be considered improper that he should express his views clearly and strongly.

The further consideration of the report of the Executive Committee was adjourned.

On the motion of Dr. PITMAN, seconded by Dr. SMITH, Sections I. and IV. of the Standing Orders were referred to the Business Committee to report whether they would recommend any, and if so what, alterations and additions in those sections.

The Council then adjourned.

THURSDAY, APRIL 28TH.

At the meeting of the Council to-day, the adjourned consideration of the report of the Executive Committee in regard to certain students from India was resumed, and after some discussion it was resolved, "That in cases where for some special reason candidates for admission to professional examinations by the licensing bodies may not be able to comply with all the recommendations of the Council as regards examination in general education and registration thereon, exceptions may be allowed;" and it was referred to the Executive Committee to prepare for the consideration of the Council draft rules defining the classes of cases in which such exceptions might properly be allowed.

The remainder of the sitting was occupied with dental business and the discussion of a motion by Dr. Storrar, "That every registered dentist holding any of the surgical qualifications recited in Schedule A of the Medical Act shall be entitled to have such qualification or qualifications recorded on the Dentists' Register, as evidence of a higher degree of knowledge." After an animated debate the motion was carried by 13 against 5, thus reversing the action of the Council at its previous meeting, when it was decided to erase the additional qualifications that had been placed in the Dentists' Register. The Council then adjourned.

A fuller report of this sitting will appear in our next issue.

RECENT DISCOVERIES IN PHYSICS.

SEVERAL very remarkable discoveries in physics have appeared during the last few months. The connexion of physics with chemistry has of late years become more intimate than ever, and many of the most distinguished chemists, both in England and abroad, have in consequence been working in physical lines, hoping by the investigation of molecular physics to gain light in regard to what are commonly called chemical phenomena and chemical laws. A short review of some of the more striking of the results so obtained will interest our readers.

Professor Carnelley's singular discovery of "hot ice" deserves the first notice. It has long been known that the melting-point of ice is lowered by pressure. Ice subjected to the rapid action of an hydraulic press liquefies, and when the pressure is removed freezes again, taking, of course, the form of the mould or other vessel which contains it. The movement of a glacier through a tortuous valley is explained on this principle, the ice in turning corners being melted by the pressure and freezing again into the new form. Professor Carnelley now finds that reduction of the pressure on ice raises its melting point to an extent that could never have been anticipated. A large globe is connected by a short thick india-rubber tube with a glass tube five feet long. The whole is filled with mercury, and the free end of the tube opened under mercury. Of course the mercury leaves the flask and falls in the tube until it stands at a height of about 30 inches. The flask and upper part of the tube are now vacuous, and in fact the instrument is a barometer. The flask is then bent over on its side, and covered with ice and salt. A little water is then injected into the tube, and soon freezes by its own evaporation. We have now practically a cryophorus. A thermometer has previously been fixed in the tube in such a position that its bulb is surrounded by the newly formed ice. If now the heat of a large flame is applied to the outside of the tube the ice evaporates but does not melt, and the thermometer immersed in it is seen to rise, in some experiments as high as 356° F., or very much higher than the boiling point of water. That the ice is really hot is proved by another experiment—a piece of ice prepared in vacuo in the above manner is allowed to fall into water at about 56° F. The water is actually *heated*, and not cooled by the ice.

Similar experiments can be made with corrosive sublimate and with camphor. Camphor is melted in a tube and the air pumped out. It solidifies at once, and no further application of heat will melt it; but when air is let in, instant liquefaction takes place and the camphor boils furiously.

Not less important, though less popularly interesting, are Mr. Crookes's lately published experiments on the viscosity of gases. This curious property of gases is defined as their internal friction—the resistance they offer to the gliding of one portion over another. Now, in 1859, Professor Clerk Maxwell deduced from the mechanical theory of gases the remarkable conclusion that the viscosity should be independent of the density of the gas; and a few years later he supplied experimental proof that within certain considerable limits this theoretical law was true. But it was seen that the law could not apply if the density of the gas were reduced below a certain point not reached in Maxwell's experiments. The viscosity of a gas is intimately connected with what is called the "mean free path" of its molecules. This mean free path is most simply described as the average distance through which each molecule passes before coming into collision with another molecule, and in all ordinary vacua it is a very small distance. But Mr. Crookes, with his wonderful experimental skill and scientific acumen, has pushed the research into regions of gaseous matter where tension is measured in millionths of an atmosphere. Gas in this state is not gas in the common sense of the word, but a fourth condition of matter. The number of its molecules being so greatly reduced, their mean free path is greatly increased, so that it can be measured by inches, or even by feet, and as a consequence the viscosity of the gas almost fades away. In fact, the curve which represents the increase of mean free path also represents approximately the diminution of viscosity. No one can yet appraise the value of this discovery, or the importance of the consequences which may flow from it.

Professor Tyndall's latest contribution to science is but a confirmation, with new apparatus, of results which he had previously obtained, and is an application of a well-known and recent discovery. But the application is so novel, and the thought which suggested it is so brilliant, that science has gained a most important method. Years ago Professor Tyndall showed that gases differed greatly in their power of absorbing and emitting radiant heat. Oxygen, hydrogen, and nitrogen absorbed and emitted almost none, and aqueous vapour—to take a single example—very much. These observations have been controverted by scientific men of recognised skill, and Professor Tyndall has therefore sought for a method perfectly unlike his old one by which to test their truth. No one can deny that his search has been successful.

Rays of electric light—for which, in subsequent experiments, rays of lime light, candles, and even those of a bar of hot iron not visibly luminous, were substituted—were allowed to pass through slits or notches in a revolving disc, and thence to a flask containing the gas or vapour to be examined. On the other side of this flask a tube was placed, by which any sound could be carried to the ear of the observer. When the flask contained perfectly dry air, or any gas which was unable to absorb obscure heat rays, no effect of any kind was perceived; but when any trace of aqueous vapour or any of the gases or vapour which had previously been found to absorb heat were present, a musical note was at once produced. The rays of heat are broken and converted into successive impacts by the slits or notches; and these impacts, if absorbed by the gas, produce momentary expansions, which, repeated with sufficient frequency, give rise to musical notes.

Professor Tyndall finds ordinary fire-damp to be a good absorber of radiant heat. The sounds which it emits are very powerful, and it is hoped that a really satisfactory fire-damp indicator may at last be obtained from this totally unexpected source.

A TESTIMONIAL has been presented to Mr. G. W. Hamilton Cumming, on his resignation of the office of house-surgeon, by the weekly board, medical staff, nurses, and friends connected with the Torbay Hospital, as a mark of their high appreciation of services rendered at a critical period.

THE LANCET.

LONDON: SATURDAY, APRIL 30, 1881.

THE meeting of the Medical Council at this particular time is a mystery. There is nothing in the President's opening speech, or in the proceedings up to the moment of our writing, to explain or to justify the calling together of the Council at the present time. When we announced, some weeks ago, that the Council was summoned for the 26th inst., we confessed ourselves quite unable to understand the fact. We find that many members of that august body labour under a similar disability. As usual, when there is nothing particular for the Council to do, it spends hours upon hours in reviewing its old or its recent Recommendations on Preliminary Education. It is within our knowledge that the meeting was arranged for without any consultation with the Irish members; and it is proper to mention that Dr. HAUGHTON, more competent, perhaps, than any member of the Council to speak on matters of Preliminary Education, is conspicuous by his absence, the time being inconvenient to him. The apologetic tone of the President's own speech is the best proof that nothing in the nature of business is the real explanation of the meeting at the present moment. The speech is full of allusions to the pending inquiry by a Royal Commission, and to the undesirableness of any serious changes in the regulations of the Council. The Council, it is suggested, had better defer requiring the observance of its regulations of last year in regard to preliminary and preliminary scientific subjects till after the report of the forthcoming Commission. "Were it not for the appointment of the Royal Commission," the Executive Committee would have been prepared to suggest changes for diminishing the expenses and facilitating the work of the Council, &c. In the face of such reflections we are increasingly puzzled to know what has brought the Council together for a fragmentary sitting—the second this year. The business that has been done would all have kept till July. The President's speech, including the suppressed or implied denunciation of those wicked persons who delight in parliamentary agitation, would have been as effective in July as in April. The removal of a name from the Register would have been as effective in July as now. The appointment of a Committee to consider the preparation of the next edition of the Pharmacopœia, and to report year by year as to addenda to the Pharmacopœia, is a very proper step, but equally fails to explain the meeting of the Council at present. It may be said that the Recommendations of the Council last year as regards the institution of a preliminary scientific examination, and the answers of the Bodies thereto, demanded a meeting of the Council. But what says the Report of the Committee that was appointed specifically to watch over this subject? It says that some answers have not yet been received; and as it would manifestly be undesirable to present a final Report, which would necessarily be incomplete, the Committee proposes to report fully at the next meeting. Clearly, therefore, this subject cannot be taken up at this meeting of the Council, even if the impending Royal Commission did not, as Dr. ACLAND suggests, make any disposal of it at present impossible. There remains the reported determination of the College of Surgeons to discontinue its Preliminary Examinations, conducted at present by the College of Preceptors under the authority of the College. But this decision is not to take effect till December of this year. Altogether, we are completely puzzled to explain the meeting of the Council, and more than ever amazed at the undignified position in which it places itself year after year in nibbling at Preliminary Education, to the embarrassment of the universities and other national educational institutions. Under these circumstances we are driven to seek for other explanations of the meeting of the Council at this particular moment, and to attribute it to some social feeling on the part of the President or some of the more influential members. We should not venture to imply that the President is perplexed with "thoughts of change" and a desire to see the Council a few times more in its present form. No such thought is possible to one who believes so devoutly in the absolute perfection of the body over which he presides, and who regards so complacently everything that it has done and left undone. We can only hope the members of the Royal Commission will study the proceedings of the present meeting in connexion with those of the last and preceding years, to see how interminably the Council revolves round the question of Preliminary Education, leaving the great subject of Medical Education, for promoting which it mainly exists, to take care of itself.

◆

THE question raised by the line of conduct adopted—and, as it would seem, specifically recommended by the then President of the College of Physicians and others—in relation to the consultations held in a recent case between a Fellow of the College and a reputed homœopathist, is one of exceeding gravity, and concerns the public as urgently and as seriously as it concerns the medical profession. It is, above all other considerations, important that the discussion, which must proceed until the issue is finally adjusted, should be lifted out of the region of professional politics. Some of our lay contemporaries, not looking at the matter from a practical standpoint, have characterised the controversy as the outcome of a system of "trades-unionism," conceived in a spirit of "exclusiveness," among men animated by a feeling of selfishness and regard for "trade interests." If the truth were known, the facts would direct the judgment of every impartial on-looker to a totally opposite conclusion. In reply to such a charge it may be contended that it is clearly to the advantage of a profession to be united, and the exclusion of any class of practitioners from the fellowship of the body as a whole must entail loss and inconvenience upon the community. The medical profession suffers in a variety of ways daily because it cannot recognise homœopathists. It is misunderstood and maligned for its supposed obstinacy, while its members are compelled to make many and grievous sacrifices of personal feeling and interest to discharge the obligations of honourable independence which the profession has imposed upon itself. It is strange that those who charge us with "exclusiveness" do not perceive that this is a fault—if fault it be—which carries with it a deterrent penalty. Obviously the consultee does not desire to be hindered in the exercise of his calling, or circumscribed as regards his constituency and *clientèle*. He is not likely to throw obstacles in his own path. He would rather consent, than decline, to meet any practitioner who asked for his assistance. In short, the profession has nothing to lose, but much to gain, by admitting homœopathists into its fellowship. It is past comprehension that this is not universally recognised. Why then do we not go when we are sent for to meet homœopaths? The answer is simply and finally that we *cannot* do so with clear consciences and as honest men. We should like to waive all difficulties. It is clearly our interest to do this; and if the case be an important one, it is perhaps not unnatural that we should chafe a good deal under the bonds of honour which hold us aloof, and strive might and main to make the divergent lines of inclination and duty seem to coalesce. The public may fairly assume that when a professional man is asked to render his aid, he wishes to comply with the request. Every sort of interest and inclination impels him to do so, and if he refuses it must be against his impulses, and because some weighty consideration coerces him. Again, the opposition we offer cannot arise from any desire to "crush out homœopathy," because there is everything in the mode of practice under that "system" to render it attractive to the professional man who adopts it. In so far as it is consistently practised, it goes by rule of thumb, and must relieve the physician from an infinity of scientific labour, thought, and anxiety. In short, the profession has no interest to be served, or object to be gained, in opposing homœopathy, or in declining to fraternise with homœopathists, and in so far as it restrains itself from a compliant course of conduct, and suffers the loss and annoyance entailed by "exclusiveness," it has a right to claim the respect due to an honourable policy and to resent the imputation of selfishness. We are unable to meet homœopathists because the light in which they view disease, and the principles on which they propose to treat it, are wholly at variance with those which every step forward in the cognate sciences of pathology and therapy confirms and demonstrates. There is no common ground for the homœopathist and the ordinary practitioner, and they cannot therefore consult; still less can they work together.

Now comes the question why we cannot—or, as our censors put it, will not—co-operate with homœopaths when these gentlemen lay aside their peculiar views, with the tenets of their distinctive school, and consent to act on ordinary principles, or to place themselves under the control of the consultee, engaging—and honourably fulfilling the engagement, even against their own better judgments—to carry out all his directions and prescriptions? We cannot answer this interrogation more explicitly than by adopting the phrase employed by Sir WILLIAM GULL last week, and saying we are unable to respect or trust any man who has "two sets of convictions." If the question at issue were a matter of taste, or even policy, in respect to a subject of minor importance, we might subordinate our opinions to the exigencies of the moment; but the greater the urgency of the summons addressed to us, and the more important the case, the greater is the need of strict rectitude. We cannot honestly beg the question, because the issues at stake may be those of life and death. These are not less solemn than the tenets of religion. We could not offer a dying man a choice of Judaism or Christianity—that is, if we ourselves believed in either. Of course, if we started by being sceptics in religion, it might be possible to meet the need of the moment by gratifying the wishes of the sick person or his friends; but this is not the attitude which the profession assumes towards science. Whatever other faults it may have, it is not faithless. Nor can we take the position occupied by those gentlemen who, having "two sets of convictions," assert their right to pick out the "good" things of all systems! Is the minister of religion entitled to serve GOD and Baal alternatively? Is the physician at liberty to obey the dictates of science or of his own instinct, at pleasure? Is it conceivable that Nature has contradictory laws at work in her system? Is it not rather likely that we err by misreading the lessons of her work? We, from our standpoint, are prepared to contend that the "law" of cure by similars is, in every case and under all its forms and applications, a scientific fallacy. We regard it as a misleading and mischievous dogma based on a misapprehension of the data from which it is professedly derived. Therefore we reject it; but those who hold it to be a law of nature are bound to obey it. How is it possible for us to meet a man who avows an alternative or an eclectic belief in the blackness of white and the whiteness of black? The proposal to consult with a physician who has "two sets of convictions" as to disease and its treatment, is an insult to common sense. Such a man must either be hopelessly lost in a fog, or he cannot be thoroughly in earnest in respect to matters of the highest and most urgent concern. Of the two we should have less objection to meet a "homœopath" pure and simple than a practitioner who either becomes all things to all men or claims to be eclectic. The "eclectic" school of physic is the most mischievous extant. It is just now a thorn in the flesh of humanity in America, and this claim to the exercise of a discretionary right to use all systems alike, seeking "the good in each," is the worst possible embodiment of *eclecticism!* The position assumed is that of an empiricist, bound by no law of the science of Nature, but prepared to undertake the treatment of disease, and to fight the battle against death, in obedience to some inner instinct to which no sane man is justified in giving heed. If the treatment of disease is to become a matter of feeling, akin to inspiration, either physic will degenerate into charlatanry, or the healing of the body must be handed back to the care of the priests. Society cannot be safe in the presence of medicine practised by inspiration unless the mission is worked out by a recognised clergy subject to ecclesiastical discipline. Science has nothing whatever to say to such a system or practice. If this pretension is to be admitted, the practitioners of scientific medicine must quit the field.

It is important that the public should understand this question fully and clearly. What we call "scientific medicine" is the science and art of healing based on a patient and ever-progressive investigation of the laws of life in health (physiology) and of the causes and effects of disease (pathology); side by side with which there is a ceaseless search for new remedies, new methods of treatment, and new light on the action of known drugs, and old modes of treatment (therapeutics and materia medica). These principal branches of science are pursued with the aid of other branches (e.g., anatomy, chemistry, botany, &c.), also comprised in the architectonic of Medicine. All the provinces investigated lie within the domain of Nature, and the natural method is adopted in research. It follows that, even if *similia similibus curantur* were true—whereas it is false,—science could not accept it as the dogma of a school, because it arrests, and affects to supersede, the necessity for deep inquiry, by dignifying with the name of a "law of action" what is simply a surface feature of the *seeming* relations subsisting between a certain class of causes and effects. When, therefore, a man says, sometimes "like cures like" and at other times "contrary cures contrary," he is surrendering the last vestige of a claim to be recognised as a scientific practitioner, seeing that he professes to have "two sets of convictions," which are mutually destructive, and neither true, because they are *incomplete.* The parade of either, or both, of these alternative doctrines is as rational as, and no more reasonable than, it would be to say "like cures like" because the cold of a thaw is followed by the end of a frost, and "contrary cures contrary" because the light of day dispels the darkness of night! There is an egregious fallacy underlying each proposition, and the supreme folly of the attempt to embody either as a doctrine of science is apparent on the face of the fact that they are surface deductions from data which have neither been tested nor explored. Whether we regard the alternative "sets of convictions" held by those gentlemen who practise homœopathy and what they are pleased to call "allopathy," at discretion, as relating to sound systems or to misconceptions of fact, it must be obvious that it is equally impossible we should consult with those who hold them. No man can honourably engage in the practice of medicine who is not severely and righteously in earnest, and who is not fairly grounded in the principles of his scientific belief; and the profession, as a whole, is convinced, and will adhere to its conviction, that no two physicians can, or ought to pretend to, consult together except they be agreed.

There can be nothing but compromise—and compromise inimical to the health-interests of the patient, reducing instead of increasing his chances of recovery—when "homœopath" meets "allopath" in consultation. In the, hitherto unprecedented, case in which one of the two voluntarily divests himself of his professional character and consents to act as an assistant or nurse, carrying out "all the directions and prescriptions" of his chief, there could, of course, be no *consultation*, and the patient is simply treated by the so-called consultee. When "homœopath" and "allopath" meet, one treats symptoms, the other treats causes and states. The one looks for "indications" for the application of the principle "like cures like," while the other is striving to penetrate the underlying conditions of the morbid state, and searching for remedies to modify them, and so change it. The one is acting against the disease, the other acting with it. We will, for the sake of argument, concede that either method might, perhaps, benefit the patient; but it must be self-evident that a compromise of two modes of procedure so antagonistic as these are must end in the negation of both, and that the patient can be helped by neither system, while both stand in the way of his possible relief. Scientific medicine can never be made subservient to such a compromise as this, and honourable men must refuse to be parties to it. We are not actuated by any prejudice or stirred by any spirit of "trades-unionism" in making this avowal. It must, sooner or later, be seen to be the only logical and tenable position in the matter. We cannot trim our sails to catch the wind of popular doctrine on this subject. Sir WILLIAM JENNER embodied the mature judgment of the profession in his action in the recent most regrettable difficulty, and Sir WILLIAM GULL has adopted the view taken, and endorsed the decision. Sir WILLIAM JENNER is now President of the Royal College of Physicians, and we may, therefore, cherish the hope that a better and healthier state of professional morals will prevail in the medical body than that which led to a sacrifice of principle when the patient was an "illustrious invalid."

IN a recent number of THE LANCET we directed the attention of the profession to Battey's operation, or spaying of women. Since that time an article by Dr. SAVAGE, entitled "Oöphorectomy," has appeared in the April number of the *Birmingham Medical Review.* This paper gives a brief account of "twenty-five consecutive successful cases" in which the ovaries had been removed. Both ovaries were ablated in twenty-four of the cases, and one only in one case, the removal of the other being found impracticable owing to adhesions, as well in a first as in a second attempt made fifteen months subsequently. The operations in the series were undertaken for various reasons, such as ovarian pain, dysmenorrhœa, absence of the vagina and undeveloped uterus, myoma, prolapse of the ovaries, and hystero-epilepsy. In the course of the operations, or after, various pathological conditions were found, such as adherent ovaries, shrivelled ovaries, and cystic ovaries. The ovaries were manifestly diseased in nineteen of the cases, while they were apparently healthy in six only. The parts removed—these being ovaries or ovaries with portions of the Fallopian tubes—varied in weight from 30 grains to 310 grains. The first case of the series was operated upon in January, 1878; the second in January, 1879; and the remainder during 1880 and 1881. It appears that besides this series of twenty-five cases, the author has "had a few cases (of myoma) where simply an exploratory incision has been made, and nothing else done, either because the tumour for some reason, as size, thickness of stump, relations, &c., was incapable of removal, or the ovaries could not be reached, and yet in the course of a few weeks afterwards, the tumour showed a clear decrease in size." Moreover, "In the case of E. H—— not in this series, and which I class as one of incomplete oöphorectomy, both ovaries were so tied down by adhesions that I felt it impossible to remove them."

We have made the above quotations in order to draw attention to the fact that we do not think the author has done justice to himself, the profession, or science, by publishing a series of successful cases, while he had had in the course of his practice some cases in which the operation could not be completed. The operation of spaying is at present on its trial, and it is neither right nor just to publish successful cases only, withholding those that are unsuccessful. In saying this, we entirely acquit Dr. SAVAGE of any unworthy motive in publishing his successful cases; but we are of opinion that he has fallen into error in not adding his unsuccessful ones. We trust that he will soon publish them.

The paper presents some points deserving of attention, and at the same time demands criticism. The author evidently has no little faith in the capabilities of the operation, for he states "as experience increases I am sure that the field for its benefits widens, and that it will gradually attain to a well-deserved reputation, and be carried out in many more and different cases than were at first proposed for its adoption." Unfortunately, in so far as this series of cases goes, such a conclusion is by no means justified, for the cases are so briefly recorded that it is not possible for the reader to form for himself any conclusion as to the necessity or desirability of the procedure. In an operation like spaying, which holds a peculiar position, and differs from all or most other operations, in that it unfits the subject for one of the chief objects of her existence; in the fact that the condition of the organs to be removed can, as a rule, not be diagnosed beforehand; and, further, in the fact that the conditions (reflex neuroses and pain) for which the operation is often undertaken have not and cannot at present be proved to be dependent upon the organs to be removed—an operation which is on its trial, and, we must add, one open to abuse,—every case in which it is performed, be it successful or fatal, complete, incomplete, or exploratory, should be recorded in detail, with the reasons for undertaking the operation. It is in this way only that the necessity or desirability of oöphorectomy can be judged of, and it is by this means also that a scientific estimate of the operation can be ultimately formed, and the limitations formulated with which it should unquestionably be hedged about. Every operation of this kind performed in our present state of knowledge is necessarily an experiment in physiology and pathology, and for this and reasons already named a full history of the case before and after the operation, as well as a minute description of the parts removed, should be placed on record. Not only should all cases in which the proceeding was successful as far as the possibility of the removal of the ovaries was concerned be recorded, but all exploratory and incomplete operations having removal of the ovaries as a chief or alternative object should be published. Such cases occur to all operators, and these contribute, no less than the successful ones, to the formation of a correct estimate of the value of spaying. The results of the operation should also be published. The cases should be watched for a protracted period afterwards—months or perhaps years; for the real effects of the mutilation do not appear to show themselves immediately in all cases. Speaking of ovarian dysmenorrhœa, Dr. SAVAGE says: "The effects of oöphorectomy in this class of disorders are well known not to be always immediate, and hence we must allow a certain time—say twelve months or so—before we can form a reliable opinion as to its benefits or otherwise in a particular case; and it is not difficult to conceive of the continuance of painful impressions and other abnormal sensations even for some time after the cause which produced them has been taken away." It should also be added that the reverse of this may happen: suffering may be relieved for a time and return after several months. This necessitates the watching for a prolonged period of all cases operated upon, for without a knowledge of the ultimate result no case can contribute to place the operation upon a proper and scientific basis. Now, in the series before us twenty of the cases were operated on since the beginning of last July—some as recently as last February,—and consequently a sufficient time has not elapsed to enable trustworthy conclusions to be formed with regard to them. Moreover, the author states: "I have not taken accurate notes of the question of menstruation afterwards, but I have a strong impression that it has not occurred more than once or twice in any of the patients, and that the large majority have not menstruated at all." We cannot refrain from asking: What is the value of cases so imperfectly recorded? They justify one conclusion, and one only—viz., that the ovaries in a large number of cases can be successfully removed, an inference we should have been perfectly warranted in forming from the success which has been obtained in ovariotomy.

There is one other point we would draw attention to—the fact mentioned by Dr. SAVAGE, that in some cases myomata diminish in size after an exploratory incision only has been made. This is very curious and very important, and is certainly not in favour of the operation of spaying. We deeply regret that the record of these cases is so meagre, for it is no small loss to science. A full and complete account of these twenty-five cases, and of the others upon which the author has operated, a full past history of the patient, a detailed description of the parts removed, and a full history of the patient for a year or two after the operation, would have been invaluable in the present state of our knowledge. We trust that the author will be able at some future time to supply these data, for without them this series of operations can be of but little value; it serves not to establish the operation upon a proper basis, but to make immediate recovery from it prominent, and, at the same time, to put out of sight the great object of the operation, permanent restoration to health, and in so far it is misleading. In making these observations we do not intend them specially for the author of this paper, but for all who undertake Battey's operation. There has been a great deal too much of immediate publication of results, especially when successful, and there have been too many scanty records of the operation published, so that it is not possible to form any trustworthy estimate of the value and place of spaying as a remedy for disease.

Annotations.

"Ne quid nimis."

THE ROYAL COMMISSION ON MEDICAL LEGISLATION.

WE have reason to believe that the following names will be submitted to the Queen:—The Master of the Rolls (Sir George Jessel), the Bishop of Peterborough, Lord Camperdown, Lord Reay, Mr. Sclater-Booth, M.P., Mr. Cohen, M.P., Mr. Huxley, Sir William Jenner, Bart., K.C.B. (President of the Royal College of Physicians), Mr. Simon, C.B., Professor Turner (of Edinburgh), and Dr. Macdonnell (of Dublin). We should gladly have seen the name of Mr. Erichsen (President of the Royal College of Surgeons), who has long been identified with medical education, examinations, and legislation during the last quarter of a century, on the list. There is, however, ample promise of energy in the *personnel* of the Commission as provisionally constituted, and it includes names which afford a guarantee for the earnestness and completeness of the inquiry to be prosecuted.

MURDER, NOT "SUICIDE," OF THE SULTAN ABDUL AZIZ.

WHEN the official statement appeared to the effect that the ex-Sultan Abdul Aziz had committed suicide, we discussed the story at length on medical and general grounds, and wrote as follows (THE LANCET, June 10th, 1876):—"The ex-Sultan was of a singularly inert temperament. Those who saw something of him when in England are not likely to be the first to accept the story of his self-slaughter by the method alleged. He might, it will be contended, have taken poison if he could have procured it, but scarcely stabbed himself in the *arms* with a pair of scissors! Setting these and many other considerations aside, it is difficult, we repeat, to conceive that suicide, by an act of this nature, is probable. We hear nothing of any measures being taken to secure a free flow of blood from the opened veins, such as were familiar to the old-fashioned phlebotomists. There might even appear to be a sinister intention in the statement that an ex-Sultan, dying by his own design, selected as an instrument an implement so exclusively the tool, or possibly the weapon, of a woman. The sudden death, the strange story told in explanation, and the hasty interment, combine to make the whole affair a mystery. This is the impression produced by the story, and such are the inferences derived from the general facts and circumstances of the case. We are, however, confronted by a document signed by nineteen physicians of various nationalities describing the appearances, and attesting that in their judgment the case was one of suicide." The accuracy of the conclusion at which we arrived, after a careful examination of the evidence available at the moment for the formation of an independent judgment, is now, it seems, demonstrated by the confession of one of his assassins. "At the instigation of a certain Mohmoud Bey, who was formerly a high official, and has been for the last four years a member of the State Council, three servants of the Sultan Murad, and a Palace secretary, called Bahú Bey, have been arrested, and the three former have, it is said, confessed to having taken part in the assassination of the late Sultan. One of the three, a professional wrestler, celebrated for his great muscular strength, is said to have held His Majesty while another opened the principal veins of his arm with a pair of scissors."

OVER-WORKING THE UNDEVELOPED BRAIN.

"OVER-WORK," properly so-called, can only occur when the organ upon which the stress of the labour falls is as yet immature, and, therefore, in process of development. When an organ has reached the maturity of its growth it can only work up to the level of its capacity or faculty for work! Fatigue may produce exhaustion, but that exhaustion will come soon enough to save the organ. Repeated "efforts" may, under abnormal conditions, follow each other too rapidly to allow of recuperation in the intervals of actual exertion, and as the starting-point will, in each successive instance, be lower than the previous state, there may be a gradual abasement; but even this process should not seriously injure a healthy and well-developed organ. In short, a great deal of nonsense has been said and written about the "over-work" of *mature* brains, and there are grounds for believing that an excuse has been sought for idleness, or indulgence in a valetudinarian habit, in the popular outcry on this subject which awhile ago attracted much attention. Nevertheless there can be no room to question the extreme peril of "over-work" to growing children and youths with *undeveloped* brains. The excessive use of an immature organ arrests its development by diverting the energy which should be appropriated to its growth, and consuming it in work. What happens to horses which are allowed to run races too early happens to boys and girls who are over-worked at school. The competitive system as applied to youths has produced a most ruinous effect on the mental constitution which this generation has to hand down to the next, and particularly the next-but-one ensuing. School-work should be purely and exclusively directed to development. "Cramming" the young for examination-purposes is like compelling an infant in arms to sit up before the muscles of its back are strong enough to support it in the upright position, or to sustain the weight of its body on its legs by standing, while as yet the limbs are unable to bear the burden imposed on them. A crooked spine or weak or contorted legs is the inevitable penalty of such folly. Another blunder is committed when one of the organs of the body—to wit, the brain—is worked at the expense of other parts of the organism, in face of the fact that the measure of general health is proportioned to the integrity of development, and the functional activity, of the body as a whole in the harmony of its component systems. No one organ can be developed at the expense of the rest without a corresponding weakening of the whole. These faults of "training" attain their supreme height of folly and short-sightedness when they are committed in reference to the youths destined for the public services. They are especially illustrated by the "Regulations respecting Naval Cadets" just issued, and which will take effect in June of the present year. The work of the Civil Service Commissioners in respect to these classes of the possible servants of the State is personally and racially *destructive*. Sooner or later public opinion must recognise this fact, and then perhaps the Government or the Legislature may be moved to interpose—not before, but when it is too late.

THE MEDICAL SOCIETY OF LONDON.

THE last ordinary meeting of the Medical Society for the session took place on Monday, the 25th inst., under the presidency of Dr. Broadbent. A remarkable case of so-called "villous" tumour of the rectum was shown by Mr. Goodsall, the tumour being the size of an orange, lobulated, vascular, and pedunculated. Dr. Allen Sturge read a lucid and interesting paper upon muscular atrophy, especially that form which is dependent upon affection of the anterior grey cornua of the spinal cord, seen in the acute inflammatory form in infantile paralysis in the parallel affection in the adult, and in a chronic form in progressive muscular atrophy. One of the main points raised by Dr. Sturge was the fact that the muscles involved in such cases were not those which are related together by their anatomical distribution or nervous supply, but those which are physiologically connected in the execution of movements, a point more difficult to establish in the case of complex coördinated acts than in the simpler ones. This was exemplified in two patients, the subjects of muscular atrophy. In one, the muscles flexing the elbow-joint—namely, the supinator longus, biceps, and coraco-brachialis—were wasted, the other muscles of the arms and forearms being of full size; and in the other, these flexors of the elbow were the only muscles of the limb which were not affected. Applying the same reasoning to lead palsy, Dr. Sturge thought that the selection of the affected muscles pointed to a central rather than a peripheral lesion. Dr. Gilbart Smith exhibited some of the apparatus, and many photographs in illustration of its various forms, invented by Professor Zander of Stockholm, and largely employed in the system of mechanico-therapeutics. He read a short paper descriptive of the measures aimed at in the exercise of muscles, and enumerated the affections in which it had been found most useful.—It was announced that on Monday next, May 2nd, the Annual Oration would be delivered by Mr. Durham, and the usual conversazione would take place.

DR. BROWN-SÉQUARD'S RESEARCHES.

DR. BROWN-SÉQUARD is indefatigable in his experimental investigations, and gives the results to the profession without delay. Three papers by him were read at a recent meeting of the Société de Biologie. One related to the methods of investigating the action of poisons. He believes that the methods are unreliable which are at present in use to determine whether a poison acts, after its absorption into the blood, on the nervous system or other organs, as the heart, or by an irritation of the peripheral nerves of the surface to which it is applied. His researches with chloroform, chloral, prussic acid, and other substances, have led to another mode of experimentation, which has already yielded important results. After having placed the poison in contact with the skin, or injected it beneath the skin on one side of the body, he ascertains the differences which exist between the two halves of the body in voluntary movements, sensibility, reflex action, the sensory organs, the bloodvessels, the colour of the blood, the involuntary contractions, the excitability of the nerves, the muscular irritability, cadaveric rigidity, putrefaction, the state of the kidneys, of the lungs, of the two halves of the cerebro-spinal centres, &c. The striking differences found between the two sides in the case of the animals on which Dr. Brown-Séquard has experimented with chloroform and other poisons have shown him how fertile is this new field of observation. It seems to him needless to insist that the unilateral effects which he has found to occur, on the side to which the poison has been applied, or on the opposite side, are clearly the result of an influence on the peripheral nerves, acting on the central nervous system, and not on an action produced on the latter by the presence of the poison in the circulating blood. Continuing his experiments on the effect of anæsthetics applied to the skin, Dr. Brown-Séquard has found that anhydrous chloral differs in its action from chloroform in that it can produce all its inhibitory and dynamogenetic effects when it is applied to a part of the skin which has been paralysed by the section of the dorsal spinal cord, or of the principal nerves. A larger dose of anhydrous chloral is, however, necessary to kill an animal which has been rendered paraplegic, when applied to the skin of the sacrum or loins, than is necessary to kill another animal of the same kind and size, but not paraplegic. A concentrated solution of chloral hydrate applied to the skin produces nearly the same general and unilateral effects as the anhydrous chloral. A rabbit weighing 1850 grammes died at the end of two hours by gradual arrest of the heart, the respiration being also weakened and retarded, and the temperature lowered. Twelve or thirteen cubic centimetres of a concentrated solution of chloral hydrate had been applied to the skin of the lumbar region, in small quantities, during twenty-five minutes. Anhydrous chloral must produce its effect by some other means than by its absorption in the form of chloral hydrate, for a cubic centimetre of anhydrous chloral killed a rabbit weighing 1600 grammes, when applied to the skin of the back, while the application of five, six, or seven cubic centimetres of a concentrated solution of chloral hydrate did not kill such animals, although it produced very marked toxic effects. The next day they had recovered their normal condition. The third communication related to the production of anæsthesia by stretching the medulla and cervical spinal cord, by bending down the head of the animal. The anæsthesia thus produced is often so pronounced that it is possible, without causing any notable suffering, to perform an operation ordinarily very painful—such, for example, as exposing the spinal cord and dividing it unilaterally. This experiment usually succeeds better in small than in large animals, but the anæsthetic effect is often very marked, even in dogs. Dr. Brown-Séquard reminded his hearers that he discovered long ago that this experiment causes a diminution, and even arrest, of the circulation and respiration, lowering the temperature, and even changing the colour of the venous blood, which, instead of its ordinary dark colour, becomes bright red.

POISONOUS FISH.
